5.185 IN_SET

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Used for defining constraints with set variables.

Constraint IN_SET(VAL, SET)

Synonyms DOM, MEMBER.

Arguments

VAL	:	dvar
SET	:	svar

Purpose Constraint variable VAL to belong to set SET.

Example $(3, \{1, 3\})$

Remark When SET is fixed the IN_SET constraint is referenced under the name DOM in **Gecode**.

Systems MEMBER in **Choco**, REL in **Gecode**, DOM in **Gecode**.

Used in BIPARTITE, CLIQUE, CONNECTED, CUTSET, DAG, DISCREPANCY, DISJ, INVERSE_SET, K_CUT, LINK_SET_TO_BOOLEANS, OPEN_ALLDIFFERENT, OPEN_AMONG, OPEN_ATLEAST, OPEN_ATMOST, OPEN_GLOBAL_CARDINALITY, OPEN_GLOBAL_CARDINALITY_LOW_UP, PATH_FROM_TO, PROPER_FOREST, ROOTS, STRONGLY_CONNECTED, SUM, SUM_SET, SYMMETRIC, SYMMETRIC_CARDINALITY, SYMMETRIC_GCC, TOUR.

See also **common keyword:** IN *(value constraint)*.

specialisation: IN_INTERVAL *(set variable replaced by fixed interval)*.

Keywords **constraint arguments:** constraint involving set variables.

constraint type: predefined constraint, value constraint.

modelling: included.

5.186 INCOMPARABLE

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Inspired by incomparable rectangles.

Constraint INCOMPARABLE(VECTOR1, VECTOR2)

Synonym INCOMPARABLES.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
$|\texttt{VECTOR1}| \geq 1$
$|\texttt{VECTOR2}| \geq 1$
$|\texttt{VECTOR1}| = |\texttt{VECTOR2}|$

Purpose Enforce that when the components of VECTOR1 and VECTOR2 are ordered, and respectively denoted by SVECTOR1 and SVECTOR2, we neither have $\texttt{SVECTOR1}[i].\texttt{var} \leq \texttt{SVECTOR2}[i].\texttt{var}$ (for all $i \in [1, |\texttt{SVECTOR1}|]$) nor have $\texttt{SVECTOR2}[i].\texttt{var} \leq \texttt{SVECTOR1}[i].\texttt{var}$ (for all $i \in [1, |\texttt{SVECTOR1}|]$).

Example $(\langle 16, 2\rangle, \langle 4, 11\rangle)$

The INCOMPARABLE constraint holds since $16 > 4$ and $2 < 11$.

Typical $|\texttt{VECTOR1}| > 1$

Symmetries

- Items of VECTOR1 are permutable.
- Items of VECTOR2 are permutable.
- Arguments are permutable w.r.t. permutation (VECTOR1, VECTOR2).

Used in ALL_INCOMPARABLE.

See also **implies:** LEX_DIFFERENT.

system of constraints: ALL_INCOMPARABLE.

Keywords **characteristic of a constraint:** vector.

constraint arguments: constraint between two collections of variables.

constraint type: predefined constraint.

Cond. implications

- INCOMPARABLE(VECTOR1, VECTOR2)
  with $|\texttt{VECTOR1}| = 2$
  implies DISJOINT(VARIABLES1 : VECTOR1, VARIABLES2 : VECTOR2).

- INCOMPARABLE(VECTOR1, VECTOR2)
  with $|\texttt{VECTOR1}| = 2$
  implies INT_VALUE_PRECEDE_CHAIN(VALUES : VECTOR1, VARIABLES : VECTOR2).

5.187 INCREASING

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin KOALOG

Constraint INCREASING(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restriction required(VARIABLES, var)

Purpose The variables of the collection VARIABLES are increasing.

Example $(\langle 1, 1, 4, 8\rangle)$

The INCREASING constraint holds since $1 \leq 1 \leq 4 \leq 8$.

Typical $|\text{VARIABLES}| > 2$
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

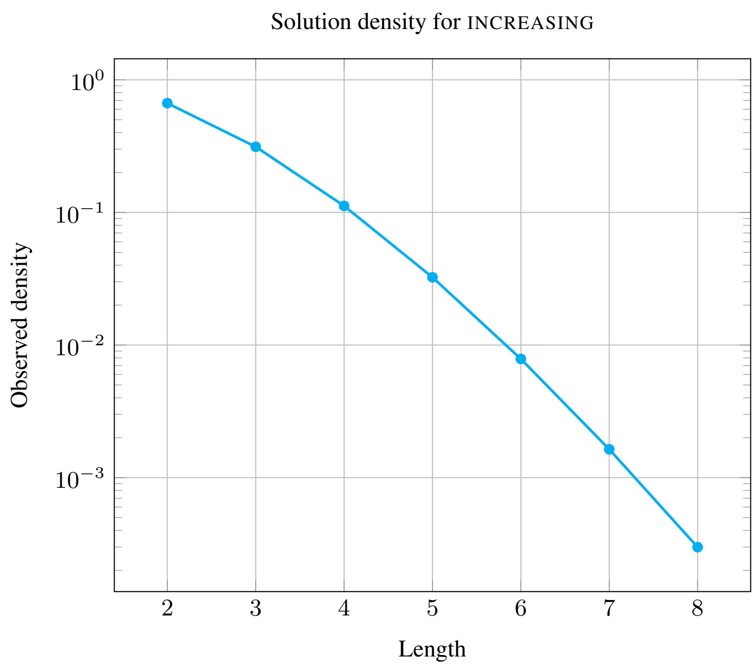
Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

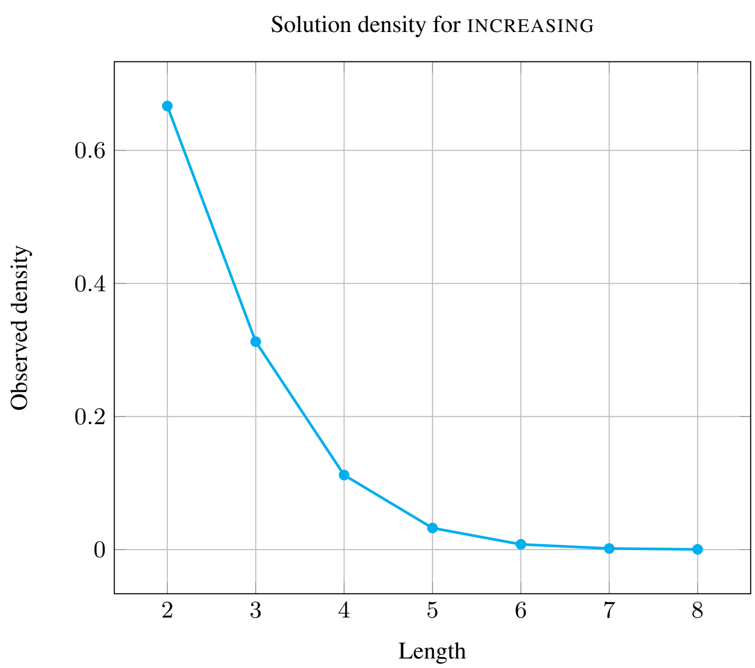
Arg. properties Contractible wrt. VARIABLES.

Counting

Length (n)	2	3	4	5	6	7	8
Solutions	6	20	70	252	924	3432	12870

Number of solutions for INCREASING: domains $0..n$





Systems INCREASINGNVALUE in **Choco**, REL in **Gecode**, INCREASING in **MiniZinc**.

Used in GLOBAL_CARDINALITY_LOW_UP, INCREASING_GLOBAL_CARDINALITY,

INCREASING_NVALUE, INCREASING_SUM, NVALUE, SUM_CTR.

5.188 INCREASING_GLOBAL_CARDINALITY

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Conjoin GLOBAL_CARDINALITY_LOW_UP and INCREASING.

Constraint INCREASING_GLOBAL_CARDINALITY(VARIABLES, VALUES)

Synonyms INCREASING_GLOBAL_CARDINALITY_LOW_UP, INCREASING_GCC, INCREASING_GCC_LOW_UP.

Arguments

VARIABLES : collection(var−dvar)
VALUES : collection(val−int, omin−int, omax−int)

Restrictions

required(VARIABLES, var)
INCREASING(VARIABLES)
$|\mathtt{VALUES}| > 0$
required(VALUES, [val, omin, omax])
distinct(VALUES, val)
$\mathtt{VALUES.omin} \geq 0$
$\mathtt{VALUES.omax} \leq |\mathtt{VARIABLES}|$
$\mathtt{VALUES.omin} \leq \mathtt{VALUES.omax}$

Purpose The variables of the collection VARIABLES are increasing. In addition, each value $\mathtt{VALUES}[i].\mathtt{val}$ $(1 \leq i \leq |\mathtt{VALUES}|)$ should be taken by at least $\mathtt{VALUES}[i].\mathtt{omin}$ and at most $\mathtt{VALUES}[i].\mathtt{omax}$ variables of the VARIABLES collection.

Example

$$\left(\begin{array}{l}\langle 3,3,6,8\rangle, \\ \left\langle\begin{array}{lll}\mathtt{val}-3 & \mathtt{omin}-2 & \mathtt{omax}-3, \\ \mathtt{val}-5 & \mathtt{omin}-0 & \mathtt{omax}-1, \\ \mathtt{val}-6 & \mathtt{omin}-1 & \mathtt{omax}-2\end{array}\right\rangle\end{array}\right)$$

The INCREASING_GLOBAL_CARDINALITY constraint holds since:

- The values of the collection $\langle 3,3,6,8\rangle$ are sorted in increasing order.
- Values 3, 5 and 6 are respectively used 2 $(2 \leq 2 \leq 3)$, 0 $(0 \leq 0 \leq 1)$ and 1 $(1 \leq 1 \leq 2)$ times within the collection $\langle 3,3,6,8\rangle$ and since no constraint was specified for value 8.

Typical

$|\mathtt{VARIABLES}| > 1$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 1$
$|\mathtt{VALUES}| > 1$
$\mathtt{VALUES.omin} \leq |\mathtt{VARIABLES}|$
$\mathtt{VALUES.omax} > 0$
$\mathtt{VALUES.omax} \leq |\mathtt{VARIABLES}|$
$|\mathtt{VARIABLES}| > |\mathtt{VALUES}|$

Typical model $\texttt{nval}(\texttt{VARIABLES.var}) > 2$

Symmetry Items of VALUES are permutable.

Usage This constraint can be used in order to break symmetry in the context of the following pattern. We have a matrix $\mathcal{M}$ of variables with the same constraint on each row and a GLOBAL_CARDINALITY_LOW_UP constraint on each column. Beside lexicographically ordering the rows of $\mathcal{M}$ with a LEX_CHAIN_LESSEQ constraint, one can also state a INCREASING_GLOBAL_CARDINALITY on the first column of $\mathcal{M}$ in order to improve propagation on the corresponding variables.

Reformulation The INCREASING_GLOBAL_CARDINALITY constraint can be expressed in term of a conjunction of a GLOBAL_CARDINALITY_LOW_UP and an INCREASING constraints. Even if we achieve arc-consistency on these two constraints this hinders propagation as shown by the following small example.

We have two variables X and Y $(X \leq Y)$, which both take their values in the set $\{2, 3\}$. In addition, assume that the minimum number of occurrences of values 0, 1 and 2 are respectively equal to 0, 1 and 1. Similarly assume that, the maximum number of occurrences of values 0, 1 and 2 are respectively equal to 1, 1 and 2. The reformulation does not reduce the domain of variables X, Y in any way, while the automaton described in the **Automaton** slot fixes X to 2 and Y to 3.

See also **implies:** GLOBAL_CARDINALITY_LOW_UP, INCREASING.

related: ORDERED_GLOBAL_CARDINALITY.

Keywords **application area:** assignment.

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: value constraint, order constraint.

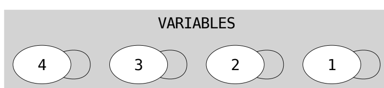
filtering: arc-consistency.

symmetry: symmetry, matrix symmetry.

For all items of VALUES:

Arc input(s)	VARIABLES
Arc generator	*SELF* $\mapsto$ collection(variables)
Arc arity	1
Arc constraint(s)	variables.var = VALUES.val
Graph property(ies)	• **NVERTEX** $\geq$ VALUES.omin • **NVERTEX** $\leq$ VALUES.omax

Graph model Since we want to express one unary constraint for each value we use the "For all items of VALUES" iterator. Part (A) of Figure 5.438 shows the initial graphs associated with each value 3, 5 and 6 of the VALUES collection of the **Example** slot. Part (B) of Figure 5.438 shows the two corresponding final graphs respectively associated with values 3 and 6 that are both assigned to the variables of the VARIABLES collection (since value 5 is not assigned to any variable of the VARIABLES collection the final graph associated with value 5 is empty). Since we use the **NVERTEX** graph property, the vertices of the final graphs are stressed in bold.



(A)

(B)

Figure 5.438: Initial and final graph of the INCREASING_GLOBAL_CARDINALITY constraint

Automaton A first systematic approach for creating an automaton that only recognises the solutions to the INCREASING_GLOBAL_CARDINALITY constraint could be to:

- First, create an automaton that recognises the solutions to the INCREASING constraint.
- Second, create an automaton that recognises the solutions to the GLOBAL_CARDINALITY_LOW_UP constraint.
- Third, make the product of the two previous automata and minimise the resulting automaton.

However this approach is not going to scale well in practice since the automaton associated with the GLOBAL_CARDINALITY_LOW_UP constraint may have a too big size. Therefore we propose an approach where we directly construct in a single step the automaton that only recognises the solutions to the INCREASING_GLOBAL_CARDINALITY constraint. Note that we do not have any formal proof that the resulting automaton is always minimum.

Without loss of generality, we assume that:

- All items of the VALUES collection are sorted in increasing value on the attribute val.
- All the potential values of the variables of the VARIABLES collection are included within the set of values of the collection VALUES (i.e., the val attribute).[9]
- All values of the VALUES collection for which the attribute omax is set to 0 cannot be assigned to the variables of the VARIABLES collection.[10]

Before defining the states of the automaton, we first need to introduce the following notion. A value $\texttt{VALUES}[v].\texttt{val}$ is *constrained by its maximum number of occurrences* if and only if $\texttt{VALUES}[v].\texttt{omax} \leq 1 \vee \texttt{VALUES}[v].\texttt{omax} < |\texttt{VARIABLES}| - \sum_{u=1,u\neq v}^{|\texttt{VALUES}|} \texttt{VALUES}[u].\texttt{omin}$.[11] Let $\mathcal{V}$ denote the set of constrained values (i.e., their indexes within the collection VALUES) by their respective maximum number of occurrences.

After determining the set $\mathcal{V}$, the omax attribute of each potential value is normalised in the following way:

- For an unconstrained value $\texttt{VALUES}[v].\texttt{val}$ we reset $\texttt{VALUES}[v].\texttt{omax}$ to $\max(1, \texttt{VALUES}[v].\texttt{omin})$.
- For a constrained value $\texttt{VALUES}[v].\texttt{val}$ we reset $\texttt{VALUES}[v].\texttt{omax}$ to 1 if its current value is smaller than 1.

We are now in position to introduce the states of the automaton.

The $1 + \sum_{v=1,v\in\mathcal{V}}^{|\texttt{VALUES}|} \texttt{VALUES}[v].\texttt{omax} + \sum_{v=1,v\notin\mathcal{V}}^{|\texttt{VALUES}|} \texttt{VALUES}[v].\texttt{omin}$ states of the automaton that only accepts solutions to the INCREASING_GLOBAL_CARDINALITY constraint are defined in the following way:

- For the v^{th} item of the collection VALUES we have:
  - If $v \in \mathcal{V}$, $\texttt{VALUES}[v].\texttt{omax}$ states labelled by s_{vo} $(1 \leq o \leq \texttt{VALUES}[v].\texttt{omax})$.

[9] If this is not the case, we can include these values within the VALUES collection and set their minimum and maximum number of occurrences to 0 and $|\texttt{VARIABLES}| - \sum_{v=1}^{|\texttt{VALUES}|} \texttt{VALUES}[v].\texttt{omin}$.

[10] We initially remove such values from all variables of the VARIABLES collection.

[11] When $\texttt{VALUES}[v].\texttt{omax} \leq 1$ we cannot reduce the number of states related to value $\texttt{VALUES}[v].\texttt{val}$ and we therefore consider that we are in the constrained case.

  – If $v \notin \mathcal{V}$, `VALUES`$[v]$.`omin` states labelled by s_{vo} ($1 \leq o \leq$ `VALUES`$[v]$.`omin`).

- We have an initial state labelled by s_{00}.

Terminal states correspond to those states s_{vo} such that, both (1) o is greater than or equal to `VALUES`$[v]$.`omin`, and (2) there is no value item `VALUES`$[w]$ ($w > v$) such that `VALUES`$[w]$.`omin` > 0. Transitions are defined in the following way:

- There is an arc, labelled by `VALUES`$[v]$.`val`, from the initial state s_{00} to every state s_{v1} where `VALUES`$[v]$ is an item for which all values `VALUES`$[u]$.`val` strictly less than `VALUES`$[v]$.`val` verify the condition `VALUES`$[u]$.`omin` $= 0$.
- For each value `VALUES`$[v]$.`val` constrained by its maximum number of occurrences (i.e., $v \in \mathcal{V}$), there is an arc, labelled by `VALUES`$[v]$.`val`, from the state s_{vk} to the state s_{vk+1} for all k in $[1,$ `VALUES`$[v]$.`omax` $- 1]$.
- For each value `VALUES`$[v]$.`val` unconstrained by its maximum number of occurrences (i.e., $v \notin \mathcal{V}$), there is an arc, labelled by `VALUES`$[v]$.`val`, from the state s_{vk} to the state s_{vk+1} for all k in $[1,$ `VALUES`$[v]$.`omin` $- 1]$. There is also a loop, labelled by `VALUES`$[v]$.`val`, from state s_{vk} to the state s_{vk} for $k =$ `VALUES`$[v]$.`omin`.
- For each value `VALUES`$[v]$.`val` constrained by its maximum number of occurrences (i.e., $v \in \mathcal{V}$), there is an arc, labelled by `VALUES`$[w]$.`val`, from state s_{vk} to state s_{w1} ($v < w$) for all k in [`VALUES`$[v]$.`omin`, `VALUES`$[v]$.`omax`] and for all w such that $\forall u \in [v+1, w-1]$: `VALUES`$[u]$.`omin` $= 0$.
- For each value `VALUES`$[v]$.`val` unconstrained by its maximum number of occurrences (i.e., $v \notin \mathcal{V}$), there is an arc, labelled by `VALUES`$[w]$.`val`, from state s_{vk} to state s_{w1} ($v < w$) for $k =$ `VALUES`$[v]$.`omin` and for all w such that $\forall u \in [v+1, w-1]$: `VALUES`$[u]$.`omin` $= 0$.

Figure 5.439 depicts the automaton associated with the INCREASING_GLOBAL_CARDINALITY constraint of the **Example** slot. For this purpose we assume without loss of generality that we have four decision variables that all take their potential values within interval $[3, 8]$. Consequently, values 4, 7 and 8 are first added to the items of the `VALUES` collection. Both values 3 and 6 are unconstrained by their respective maximum number of occurrences. Therefore their `omax` attributes are respectively reduced to 2 and 1. All other values, namely values 4, 5, 7 and 8, are constrained values. The INCREASING_GLOBAL_CARDINALITY constraint holds since the corresponding sequence of visited states, s_{00} s_{11} s_{12} s_{41} s_{61}, ends up in an accepting state (i.e., accepting states are denoted graphically by a double circle in the figure). Note that non initial states are first indexed by the position of an item within the `VALUES` collection, and not by the value itself (e.g., within s_{12} the 1 designates value 3). For instance state s_{11} depicts the fact that the automaton has already recognised a single occurrence of value 3, while s_{12} corresponds to the fact that the automaton has already seen at least two occurrences of value 3.[12]

[12] The at least comes from the loop on state s_{12}.

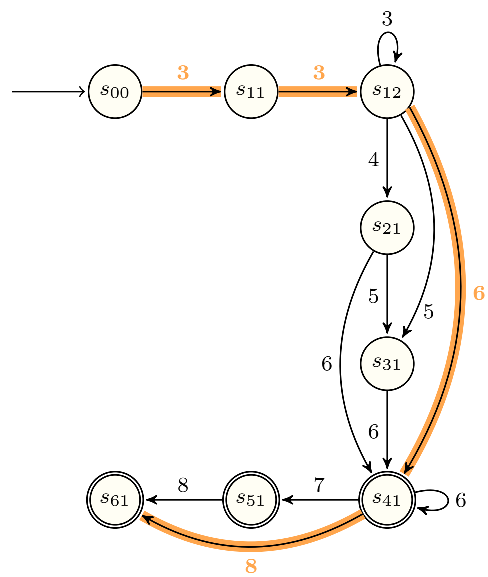


Figure 5.439: Automaton of the INCREASING_GLOBAL_CARDINALITY constraint of the **Example** slot: the path corresponding to the solution $\langle \mathbf{3}, \mathbf{3}, \mathbf{6}, \mathbf{8} \rangle$ is depicted by thick orange arcs

5.189 INCREASING_NVALUE

DESCRIPTION LINKS GRAPH AUTOMATON

Origin Conjoin NVALUE and INCREASING.

Constraint INCREASING_NVALUE(NVAL, VARIABLES)

Arguments

NVAL	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

NVAL $\geq$ min(1, |VARIABLES|)
NVAL $\leq$ |VARIABLES|
required(VARIABLES, var)
INCREASING(VARIABLES)

Purpose The variables of the collection VARIABLES are increasing. In addition, NVAL is the number of distinct values taken by the variables of the collection VARIABLES.

Example

$(2, \langle 6, 6, 8, 8, 8\rangle)$
$(1, \langle 6, 6, 6, 6, 6\rangle)$
$(5, \langle 0, 2, 3, 6, 7\rangle)$

The first INCREASING_NVALUE constraint (see Figure 5.440 for a graphical representation) holds since:

- The values of the collection $\langle 6, 6, 8, 8, 8\rangle$ are sorted in increasing order.
- NVAL $= 2$ is set to the number of distinct values occurring within the collection $\langle 6, 6, 8, 8, 8\rangle$.

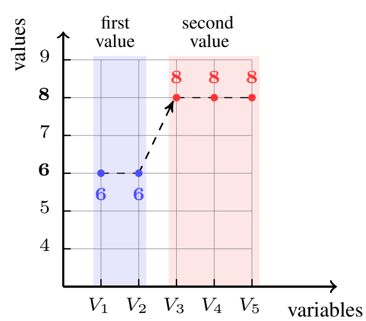

Figure 5.440: Illustration of the first example of the **Example** slot: five variables V_1, V_2, V_3, V_4, V_5 respectively fixed to values 6, 6, 8, 8 and 8, and the corresponding number of distinct values NVAL $= 2$

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

Typical model

$\texttt{nval}(\texttt{VARIABLES.var}) > 2$

Symmetry

One and the same constant can be added to the `var` attribute of all items of `VARIABLES`.

Arg. properties

Functional dependency: `NVAL` determined by `VARIABLES`.

Algorithm

A complete filtering algorithm in a linear time complexity over the sum of the domain sizes is described in [51].

Reformulation

The INCREASING_NVALUE constraint can be expressed in term of a conjunction of a NVALUE and an INCREASING constraints (i.e., a chain of non strict inequality constraints on adjacent variables of the collection `VARIABLES`). But as shown by the following example, $V_1 \in [1,2]$, $V_2 \in [1,2]$, $V_1 \leq V_2$, NVALUE$(2, \langle V_1, V_2\rangle)$, this hinders propagation (i.e., the unique solution $V_1 = 1$, $V_2 = 2$ is not directly obtained after stating all the previous constraints).

A better reformulation achieving arc-consistency uses the SEQ_BIN constraint [321] that we now introduce. Given `N` a domain variable, `X` a sequence of domain variables, and `C` and `B` two binary constraints, SEQ_BIN$(\texttt{N}, \texttt{X}, \texttt{C}, \texttt{B})$ holds if (1) `N` is equal to the number of `C`-stretches in the sequence `X`, and (2) `B` holds on any pair of consecutive variables in `X`. A `C`-stretch is a generalisation of the notion of stretch introduced by G. Pesant [316], where the equality constraint is made explicit by replacing it by a binary constraint `C`, i.e., a `C`-stretch is a maximal length subsequence of `X` for which the binary constraint `C` is satisfied on consecutive variables. INCREASING_NVALUE$(\texttt{NVAL}, \texttt{VARIABLES})$ can be reformulated as SEQ_BIN$(\texttt{NVAL}, \texttt{VARIABLES}, =, \leq)$.

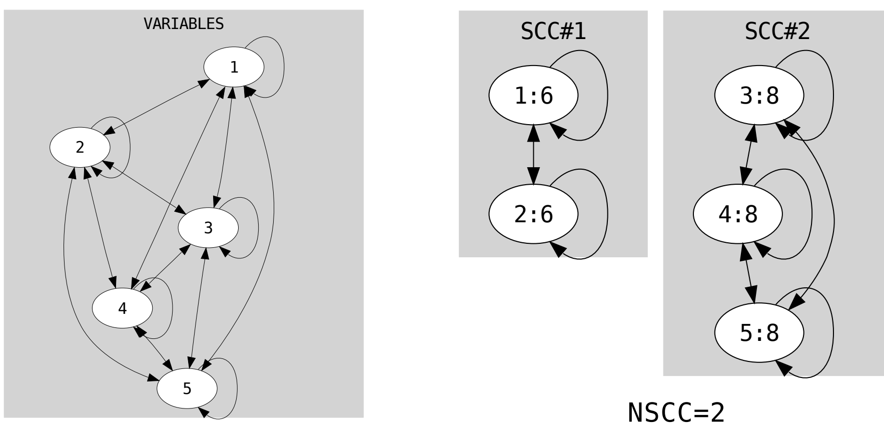
Graph model Parts (A) and (B) of Figure 5.441 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a value that is assigned to some variables of the VARIABLES collection. The 2 following values 6 and 8 are used by the variables of the VARIABLES collection.



(A) (B)

Figure 5.441: Initial and final graph of the INCREASING_NVALUE constraint

Automaton

A first systematic approach for creating an automaton that only recognises the solutions to the INCREASING_NVALUE constraint could be to:

- First, create an automaton that recognises the solutions to the INCREASING constraint.
- Second, create an automaton that recognises the solutions to the NVALUE constraint.
- Third, make the product of the two previous automata and minimise the resulting automaton.

However this approach is not going to scale well in practice since the automaton associated with the NVALUE constraint has a too big size. Therefore we propose an approach where we directly construct in a single step the automaton that only recognises the solutions to the INCREASING_NVALUE constraint. Note that we do not have any formal proof that the resulting automaton is always minimum.

Without loss of generality, assume that the collection of variables `VARIABLES` contains at least one variable (i.e., $|\texttt{VARIABLES}| \geq 1$). Let l, m, n, min and max respectively denote the minimum and maximum possible value of variable `NVAL`, the number of variables of the collection `VARIABLES`, the smallest value that can be assigned to the variables of `VARIABLES`, and the largest value that can be assigned to the variables of `VARIABLES`. Let $s = max - min + 1$ denote the total number of potential values. Clearly, the maximum number of distinct values that can be assigned to the variables of the collection `VARIABLES` cannot exceed the quantity $d = \min(m, n, s)$. The $\frac{s\cdot(s+1)}{2} - \frac{(s-d)\cdot(s-d+1)}{2} + 1$ states of the automaton that only accepts solutions to the INCREASING_NVALUE constraint can be defined in the following way:

- We have an initial state labelled by s_{00}.
- We have $\frac{s\cdot(s+1)}{2} - \frac{(s-d)\cdot(s-d+1)}{2}$ states labelled by s_{ij} $(1 \leq i \leq d, i \leq j \leq s)$. The first index i of a state s_{ij} corresponds to the number of distinct values already encountered, while the second index j denotes the the current value (i.e., more precisely the index of the current value, where the minimum value has index 1).

Terminal states depend on the possible values of variable `NVAL` and correspond to those states s_{ij} such that i is a possible value for variable `NVAL`. Note that we assume no further restriction on the domain of `NVAL` (otherwise the set of accepting states needs to be reduced in order to reflect the current set of possible values of `NVAL`). Three classes of transitions are respectively defined in the following way:

1. There is a transition, labelled by $min + j - 1$, from the initial state s_{00} to the state s_{1j} $(1 \leq j \leq s)$.
2. There is a loop, labelled by $min + j - 1$ for every state s_{ij} $(1 \leq i \leq d, i \leq j \leq s)$.
3. $\forall i \in [1, d-1], \forall j \in [i, s], \forall k \in [j+1, s]$ there is a transition labelled by $min+k-1$ from s_{ij} to s_{i+1k}.

We respectively have s transitions of class 1, $\frac{s\cdot(s+1)}{2} - \frac{(s-d)\cdot(s-d+1)}{2}$ transitions of class 2, and $\frac{(s-1)\cdot s\cdot(s+1)}{6} - \frac{(s-d)\cdot(s-d+1)\cdot(s-d+2)}{6}$ transitions of class 3.

Note that all states s_{ij} such that $i + s - j < l$ can be discarded since they do not allow to reach the minimum number of distinct values required l.

Part (A) of Figure 5.442 depicts the automaton associated with the INCREASING_NVALUE constraint of the first example of the **Example** slot. For this purpose, we assume that variable NVAL is fixed to value 2 and that variables of the collection VARIABLES take their values within interval $[6, 8]$. Part (B) of Figure 5.442 represents the simplified automaton where all states that do not allow to reach an accepting state were removed. The corresponding INCREASING_GLOBAL_CARDINALITY constraint holds since the corresponding sequence of visited states, s_{00} s_{11} s_{11} s_{23} s_{23} s_{23}, ends up in an accepting state (i.e., accepting states are denoted graphically by a double circle).

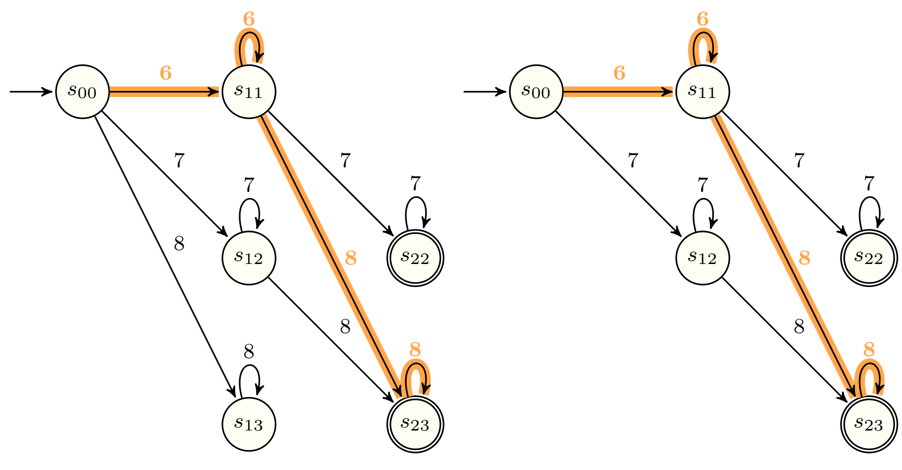


Figure 5.442: Automaton – Part (A) – and simplified automaton – Part (B) – of the INCREASING_NVALUE$(2, \langle 6, 6, 8, 8, 8\rangle)$ constraint of the first example of the **Example** slot: the path corresponding to the second argument $\langle 6, 6, 8, 8, 8\rangle$ is depicted by thick orange arcs, where the self-loop on state s_{23} is applied twice

Figure 5.443 depicts a second deterministic automaton with one counter associated with the INCREASING_NVALUE constraint, where the argument NVAL is unified to the final value of the counter.

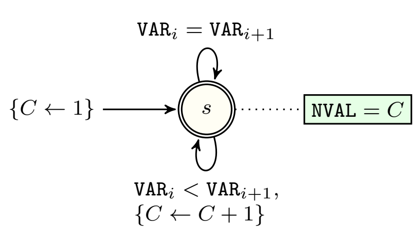

Figure 5.443: Automaton (with one counter) of the INCREASING_VALUE constraint for a non-empty collection of variables

5.190 INCREASING_NVALUE_CHAIN

DESCRIPTION LINKS GRAPH AUTOMATON

Origin Derived from INCREASING_NVALUE.

Constraint INCREASING_NVALUE_CHAIN(NVAL, VARIABLES)

Arguments

NVAL	:	dvar
VARIABLES	:	collection(b−dvar, var−dvar)

Restrictions

NVAL $\geq$ min$(1, |$VARIABLES$|)$
NVAL $\leq |$VARIABLES$|$
required(VARIABLES, [b, var])
VARIABLES.b ≥ 0
VARIABLES.b ≤ 1

Purpose

For each consecutive pair of items VARIABLES$[i]$, VARIABLES$[i+1]$ $(1 \leq i < |$VARIABLES$|)$ of the VARIABLES collection at least one of the following conditions hold:

1. VARIABLES$[i+1]$.b $= 0$,
2. VARIABLES$[i]$.var $\leq$ VARIABLES$[i+1]$.var.

In addition, NVAL is equal to number of pairs of variables VARIABLES$[i]$, VARIABLES$[i+1]$ $(1 \leq i < |$VARIABLES$|)$ plus one, which verify at least one of the following conditions:

1. VARIABLES$[i+1]$.b $= 0$,
2. VARIABLES$[i]$.var $<$ VARIABLES$[i+1]$.var.

Note that VARIABLES$[1]$.b is not referenced at all in the previous definition (i.e., its value does not influence at all the values assigned to the other variables).

Example

$$\left(6, \left\langle \begin{array}{ll} \texttt{b}-0 & \texttt{var}-2, \\ \texttt{b}-1 & \texttt{var}-4, \\ \texttt{b}-1 & \texttt{var}-4, \\ \texttt{b}-1 & \texttt{var}-4, \\ \texttt{b}-0 & \texttt{var}-4, \\ \texttt{b}-1 & \texttt{var}-8, \\ \texttt{b}-0 & \texttt{var}-1, \\ \texttt{b}-0 & \texttt{var}-7, \\ \texttt{b}-1 & \texttt{var}-7 \end{array} \right\rangle \right)$$

The INCREASING_NVALUE_CHAIN constraint holds since:

1. The condition VARIABLES$[i+1]$.b $= 0 \vee$ VARIABLES$[i]$.var $\leq$ VARIABLES$[i+1]$.var holds for every pair of adjacent items of the VARIABLES collection:

- For the pair $(\texttt{VARIABLES}[1].\texttt{var}, \texttt{VARIABLES}[2].\texttt{var})$ we have $\texttt{VARIABLES}[1].\texttt{var} \leq \texttt{VARIABLES}[2].\texttt{var}$ $(2 \leq 4)$.
- For the pair $(\texttt{VARIABLES}[2].\texttt{var}, \texttt{VARIABLES}[3].\texttt{var})$ we have $\texttt{VARIABLES}[2].\texttt{var} \leq \texttt{VARIABLES}[3].\texttt{var}$ $(4 \leq 4)$.
- For the pair $(\texttt{VARIABLES}[3].\texttt{var}, \texttt{VARIABLES}[4].\texttt{var})$ we have $\texttt{VARIABLES}[3].\texttt{var} \leq \texttt{VARIABLES}[4].\texttt{var}$ $(4 \leq 4)$.
- For the pair $(\texttt{VARIABLES}[4].\texttt{var}, \texttt{VARIABLES}[5].\texttt{var})$ we have $\texttt{VARIABLES}[5].\texttt{b} = 0$.
- For the pair $(\texttt{VARIABLES}[5].\texttt{var}, \texttt{VARIABLES}[6].\texttt{var})$ we have $\texttt{VARIABLES}[5].\texttt{var} \leq \texttt{VARIABLES}[6].\texttt{var}$ $(4 \leq 8)$.
- For the pair $(\texttt{VARIABLES}[6].\texttt{var}, \texttt{VARIABLES}[7].\texttt{var})$ we have $\texttt{VARIABLES}[7].\texttt{b} = 0$.
- For the pair $(\texttt{VARIABLES}[7].\texttt{var}, \texttt{VARIABLES}[8].\texttt{var})$ we have $\texttt{VARIABLES}[8].\texttt{b} = 0$.
- For the pair $(\texttt{VARIABLES}[8].\texttt{var}, \texttt{VARIABLES}[9].\texttt{var})$ we have $\texttt{VARIABLES}[8].\texttt{var} \leq \texttt{VARIABLES}[9].\texttt{var}$ $(7 \leq 7)$.

2. NVAL is equal to number of pairs of variables $\texttt{VARIABLES}[i], \texttt{VARIABLES}[i+1]$ $(1 \leq i < |\texttt{VARIABLES}|)$ plus one which verify at least $\texttt{VARIABLES}[i+1].\texttt{b} = 0 \vee \texttt{VARIABLES}[i].\texttt{var} < \texttt{VARIABLES}[i+1].\texttt{var}$. Beside the *plus one*, the following five pairs contribute for 1 in NVAL:

   - For the pair $(\texttt{VARIABLES}[1].\texttt{var}, \texttt{VARIABLES}[2].\texttt{var})$ we have $\texttt{VARIABLES}[1].\texttt{var} \leq \texttt{VARIABLES}[2].\texttt{var}$ $(2 < 4)$.
   - For the pair $(\texttt{VARIABLES}[4].\texttt{var}, \texttt{VARIABLES}[5].\texttt{var})$ we have $\texttt{VARIABLES}[5].\texttt{b} = 0$.
   - For the pair $(\texttt{VARIABLES}[5].\texttt{var}, \texttt{VARIABLES}[6].\texttt{var})$ we have $\texttt{VARIABLES}[5].\texttt{var} \leq \texttt{VARIABLES}[6].\texttt{var}$ $(4 < 8)$.
   - For the pair $(\texttt{VARIABLES}[6].\texttt{var}, \texttt{VARIABLES}[7].\texttt{var})$ we have $\texttt{VARIABLES}[7].\texttt{b} = 0$.
   - For the pair $(\texttt{VARIABLES}[7].\texttt{var}, \texttt{VARIABLES}[8].\texttt{var})$ we have $\texttt{VARIABLES}[8].\texttt{b} = 0$.

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{range}(\texttt{VARIABLES.b}) > 1$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

(A) **(B)**

Figure 5.444: Initial and final graph of the INCREASING_NVALUE_CHAIN constraint

Automaton Without loss of generality, assume that the collection VARIABLES contains at least one variable (i.e., $|\texttt{VARIABLES}| \geq 1$). Let l, m, n, min and max respectively denote the minimum and maximum possible value of variable NVAL, the number of items of the collection VARIABLES, the smallest value that can be assigned to $\texttt{VARIABLES}[i].\texttt{var}$ $(1 \leq i \leq n)$, and the largest value that can be assigned to $\texttt{VARIABLES}[i].\texttt{var}$ $(1 \leq i \leq n)$. Let $s = max - min + 1$ denote the total number of potential values. Clearly, the maximum value of NVAL cannot exceed the quantity $d = \min(m, n)$. The states of the automaton that only accepts solutions to the INCREASING_NVALUE_CHAIN constraint can be defined in the following way:

- We have an initial state labelled by s_{00}.
- We have $d \cdot s$ states labelled by s_{ij} $(1 \leq i \leq d, 1 \leq j \leq s)$.

Terminal states depend on the possible values of variable NVAL and correspond to those states s_{ij} such that i is a possible value for variable NVAL. Note that we assume no further restriction on the domain of NVAL (otherwise the set of accepting states needs to be reduced in order to reflect the current set of possible values of NVAL).

Transitions of the automaton are labelled by a pair of values (α, β) and correspond to a condition of the form $\texttt{VARIABLES}[i].\texttt{b} = \alpha \wedge \texttt{VARIABLES}[i].\texttt{var} = \beta$, $(1 \leq i \leq n)$. Characters $*$ and $+$ respectively represent all values in $\{0, 1\}$ and all values in $\{min, min + 1, \ldots, max\}$. Four classes of transitions are respectively defined in the following way:

1. There is a transition, labelled by the pair $(*, min + j - 1)$, from the initial state s_{00} to the state s_{1j} $(1 \leq j \leq s)$. We use the $*$ character since $\texttt{VARIABLES}[1].\texttt{b}$ is not use at all in the definition of the INCREASING_NVALUE_CHAIN constraint.
2. There is a loop, labelled by the pair $(1, min + j - 1)$ for every state s_{ij} $(1 \leq i \leq d, 1 \leq j \leq s)$.
3. $\forall i \in [1, d-1], \forall j \in [1, s], \forall k \in [j+1, s]$ there is a transition labelled by the pair $(1, min + k - 1)$ from s_{ij} to s_{i+1k}.
4. $\forall i \in [1, d-1], \forall j \in [1, s]$ there is a transition labelled by the pair $(0, +)$ from s_{ij} to $s_{i+1\,1}$.

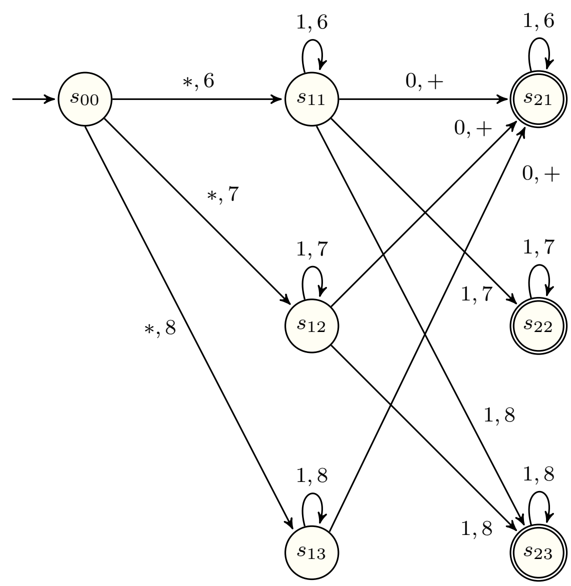

Figure 5.445: Automaton of the INCREASING_NVALUE_CHAIN constraint under the hypothesis that all variables are assigned a value in $\{6, 7, 8\}$ and that NVAL is equal to 2. The character $*$ on a transition corresponds to a 0 or to a 1 and the $+$ corresponds to a 6, 7 or 8.

5.191 INCREASING_PEAK

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Derived from PEAK and INCREASING.

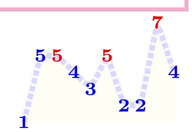
Constraint INCREASING_PEAK(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restrictions |VARIABLES| > 0
required(VARIABLES, var)

Purpose A variable V_k $(1 < k < m)$ of the sequence of variables VARIABLES $= V_1, \dots, V_m$ is a *peak* if and only if there exists an i $(1 < i \leq k)$ such that $V_{i-1} < V_i$ and $V_i = V_{i+1} = \dots = V_k$ and $V_k > V_{k+1}$.
When considering all the peaks of the sequence VARIABLES from left to right enforce all peaks to be increasing, i.e. the altitude of each peak is greater than or equal to the altitude of its preceding peak when it exists.

Example $(\langle 1, 5, 5, 3, 5, 2, 2, 7, 4\rangle)$



The INCREASING_PEAK constraint holds since the sequence 1 5 **5** 3 **5** 2 2 **7** 4 contains three peaks, in bold, that are increasing.

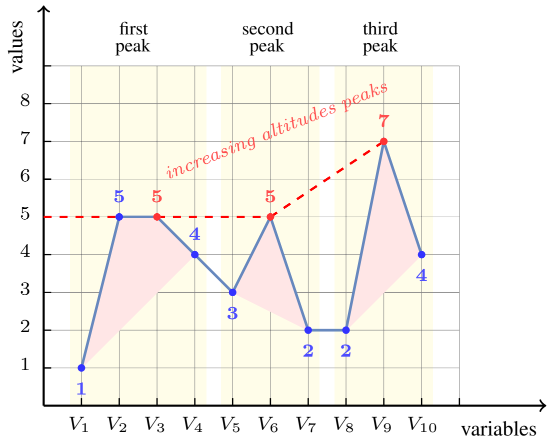


Figure 5.446: Illustration of the **Example** slot: a sequence of ten variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10} respectively fixed to values 1, 5, 5, 4, 3, 5, 2, 2, 7, 4 and its corresponding three peaks, in red, respectively located at altitudes 5, 5 and 7

Typical

$|\texttt{VARIABLES}| \geq 7$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$
$\texttt{PEAK}(\texttt{VARIABLES.var}) \geq 3$

Typical model

$\texttt{nval}(\texttt{VARIABLES.var}) > 2$

Symmetry

One and the same constant can be added to the `var` attribute of all items of `VARIABLES`.

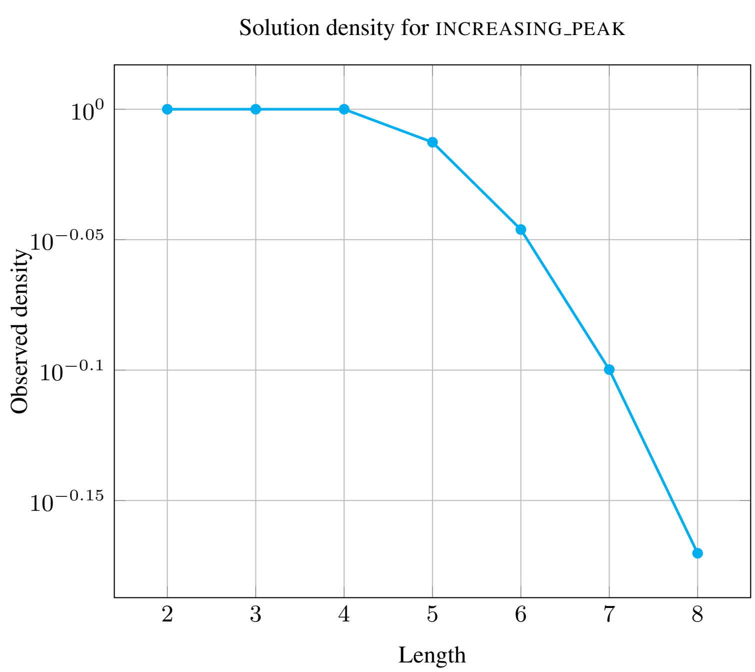
Arg. properties

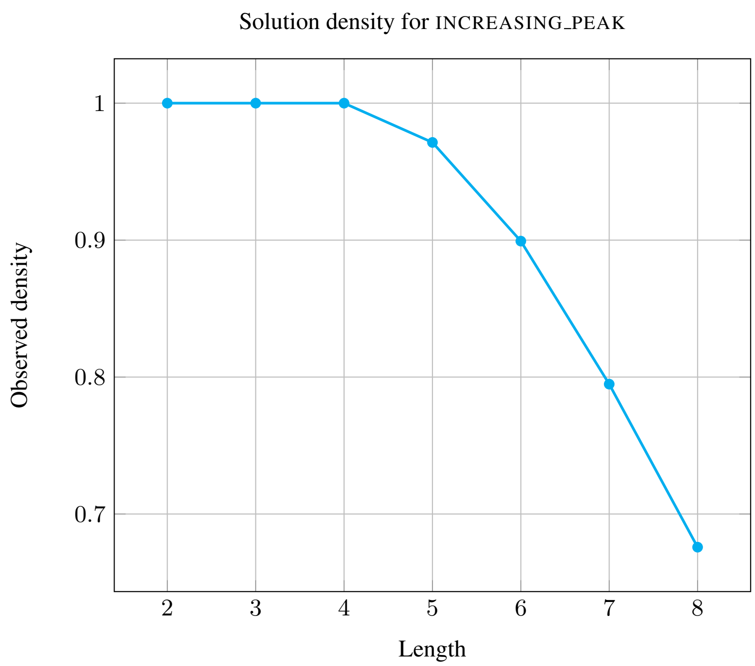
- Prefix-contractible wrt. `VARIABLES`.
- Suffix-contractible wrt. `VARIABLES`.

Counting

Length (n)	2	3	4	5	6	7	8
Solutions	9	64	625	7553	105798	1666878	29090469

Number of solutions for INCREASING_PEAK: domains $0..n$





See also **implied by:** ALL_EQUAL_PEAK.

related: DECREASING_PEAK, PEAK.

Keywords **characteristic of a constraint:** automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint network structure: sliding cyclic(1) constraint network(2).

Cond. implications INCREASING_PEAK(VARIABLES)
with PEAK(VARIABLES.var) > 0
implies NOT_ALL_EQUAL(VARIABLES).

Automaton Figure 5.447 depicts the automaton associated with the INCREASING_PEAK constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $(\mathtt{VAR}_i < \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 0) \wedge (\mathtt{VAR}_i = \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 1) \wedge (\mathtt{VAR}_i > \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 2)$.

STATE SEMANTICS

s	: initial stationary or decreasing mode	$(\{= \mid >\}^*)$
u	: increasing (before first potential peak) mode	$(< \{< \mid =\}^*)$
v	: decreasing (after a peak) mode	$(> \{> \mid =\}^*)$
w	: increasing (after a peak) mode	$(< \{< \mid =\}^*)$

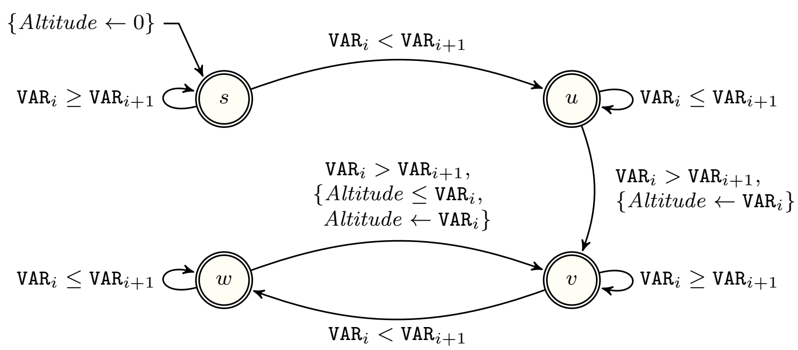


Figure 5.447: Automaton for the INCREASING_PEAK constraint (note the conditional transition from state w to state v testing that the counter $Altitude$ is less than or equal to $\mathtt{VAR}_i$ for enforcing that all peaks from left to right are in increasing altitude)

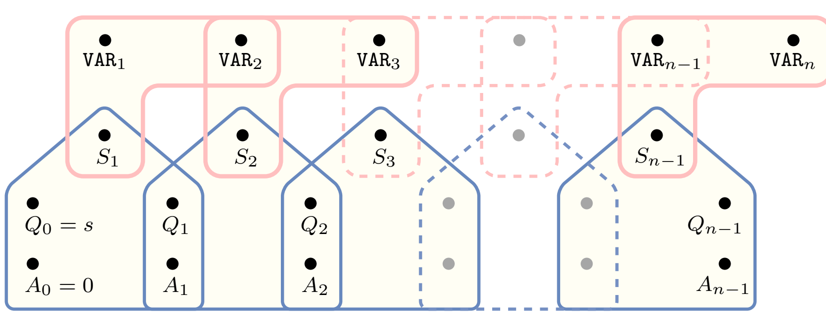

Figure 5.448: Hypergraph of the reformulation corresponding to the automaton of the INCREASING_PEAK constraint where A_i stands for the value of the counter $Altitude$ (since all states of the automaton are accepting there is no restriction on the last variable Q_{n-1})

5.192 INCREASING_SUM

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin

Conjoin INCREASING and SUM_CTR.

Constraint

INCREASING_SUM(VARIABLES, S)

Synonyms

INCREASING_SUM_CTR, INCREASING_SUM_EQ.

Arguments

VARIABLES	:	collection(var−dvar)
S	:	dvar

Restrictions

required(VARIABLES, var)
INCREASING(VARIABLES)

Purpose

The variables of the collection VARIABLES are increasing. In addition, S is the sum of the variables of the collection VARIABLES.

Example

$(\langle 3, 3, 6, 8\rangle, 20)$

The INCREASING_SUM constraint holds since:

- The values of the collection $\langle 3, 3, 6, 8\rangle$ are sorted in increasing order.
- $\mathtt{S} = 20$ is set to the sum $\langle 3 + 3 + 6 + 8\rangle$.

Typical

$|\mathtt{VARIABLES}| > 1$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 1$

Typical model

$\mathtt{nval}(\mathtt{VARIABLES.var}) > 2$

Arg. properties

Functional dependency: S determined by VARIABLES.

Usage

The INCREASING_SUM constraint can be used for breaking some symmetries in bin packing problems. Given a set of n bins with the same maximum capacity, and a set of items each of them with a specific height, the problem is to pack all items in the bins. To break symmetry we order bins by increasing use. This is done by introducing a variable x_i $(0 \leq i < n)$ for each bin i giving its use, i.e., the sum of items heights assigned to bin i, and by posting the following INCREASING_SUM$(\langle x_0, x_1, \ldots, x_{n-1}\rangle, s)$ where s denotes the sum of the heights of all the items to pack.

Algorithm

A linear time filtering algorithm achieving bound-consistency for the INCREASING_SUM constraint is described in [324]. This algorithm was motivated by the fact that achieving bound-consistency on the inequality constraints and on the sum constraint independently hinders propagation, as illustrated by the following small example, where the maximum value of x_1 is not reduced to 2: $x_1 \in [1, 3]$, $x_2 \in [2, 5]$, $s \in [5, 6]$, $x_1 < x_2$, $x_1 + x_2 = s$.

Given an INCREASING_SUM$(\langle x_0, x_1, \ldots, x_{n-1}\rangle, s)$ constraint, the bound-consistency algorithm consists of three phases:

1. A normalisation phase adjusts the minimum and maximum value of variables $x_0, x_1, \ldots, x_{n-1}$ with respect to the chain of inequalities $x_0 \leq x_1 \leq \cdots \leq x_{n-1}$. A forward phase adjusts the minimum value of $x_1, x_2, \ldots, x_{n-1}$ (i.e., $\underline{x_{i+1}} \geq \underline{x_i}$), while a backward phase adjusts the maximum value of $x_{n-2}, x_{n-1}, \ldots, x_0$ (i.e., $\overline{x_{i-1}} \leq \overline{x_i}$).

2. A phase restricts the minimum and maximum value of the sum variable s with respect to the chain of inequalities $x_0 \leq x_1 \leq \cdots \leq x_{n-1}$ (i.e., $\underline{s} \geq \sum_{0 \leq i < n} \underline{x_i}$ and $\overline{s} \leq \sum_{0 \leq i < n} \overline{x_i}$).

3. A final phase reduces the minimum and maximum value of variables $x_0, x_1, \ldots, x_{n-1}$ both from the bounds of s and from the chain of inequalities. Without loss of generality we now focus on the pruning of the maximum value of variables $x_0, x_1, \ldots, x_{n-1}$. For this purpose we first need to introduce the notion of *last intersecting index of a variable* x_i, denoted by $last_i$. This corresponds to the greatest index in $[i+1, n-1]$ such that $\overline{x_i} > \underline{x_{last_i}}$, or i if no such integer exists. Then the increase of the minimum value of s when x_i is equal to $\overline{x_i}$ is equal to $\sum_{k \in [i, last_i]} (\overline{x_i} - \underline{x_k})$. When this increase exceeds the available margin, i.e. $\overline{s} - \sum_{0 \leq i < n} \underline{x_i}$, we update the maximum value of x_i.

We illustrate a part of the final phase on the following example INCREASING_SUM$(\langle x_0, x_1, x_2, x_3, x_4, x_5 \rangle, s)$, where $x_0 \in [2,6]$, $x_1 \in [4,7]$, $x_2 \in [4,7]$, $x_3 \in [5,7]$, $x_4 \in [6,9]$, $x_5 \in [7,9]$ and $s \in [28,29]$. Observe that the domains are consistent with the first two phases of the algorithm, since,

1. the minimum (and maximum) values of variables $x_0, x_1, x_2, x_3, x_4, x_5$ are increasing,

2. the sum of the minimum of the variables $x_0, x_1, x_2, x_3, x_4, x_5$, i.e., 28 is less than or equal to the maximum value of s,

3. the sum of the maximum of the variables $x_0, x_1, x_2, x_3, x_4, x_5$, i.e., 45 is greater than or equal to the minimum value of s.

Now, assume we want to know the increase of the minimum value of s when x_0 is set to its maximum value 6. First we compute the last intersecting index of variable x_0. Since x_4 is the last variable for which the minimum value is less than or equal to maximum value of x_0 we have $last_0 = 4$. The increase is equal to $\sum_{k \in [0,4]} (\overline{x_0} - \underline{x_k}) = (6-2)+(6-4)+(6-4)+(6-5)+(6-6) = 9$. Since it exceeds the margin $29-(2+4+4+5+6+7) = 1$ we have to reduce the maximum value of x_0. How to do this incrementally is described in [324].

5.193 INCREASING_VALLEY

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Derived from VALLEY and INCREASING.

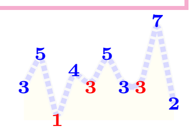
Constraint INCREASING_VALLEY(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restrictions |VARIABLES| > 0
required(VARIABLES, var)

Purpose A variable V_k $(1 < k < m)$ of the sequence of variables VARIABLES $= V_1, \ldots, V_m$ is a *valley* if and only if there exists an i $(1 < i \leq k)$ such that $V_{i-1} > V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k < V_{k+1}$.
When considering all the valleys of the sequence VARIABLES from left to right enforce all valleys to be increasing, i.e. the altitude of each valley is greater than or equal to the altitude of its preceding valley when it exists.

Example $(\langle 3, 5, 1, 4, 3, 5, 3, 3, 7, 2\rangle)$



The INCREASING_VALLEY constraint holds since the sequence 3 5 **1** 4 **3** 5 3 **3** 7 2 contains three valleys, in bold, that are increasing.

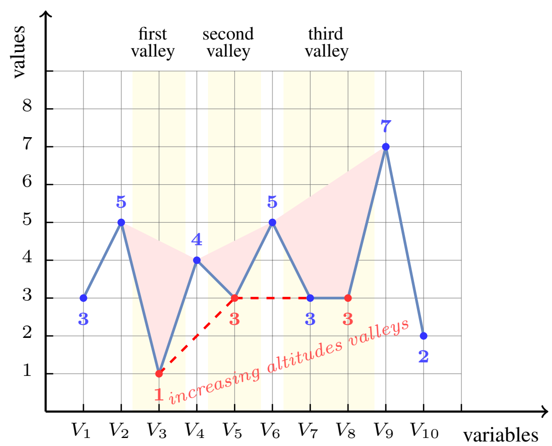


Figure 5.449: Illustration of the **Example** slot: a sequence of ten variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10} respectively fixed to values 3, 5, 1, 4, 3, 5, 3, 3, 7, 2 and its corresponding three valleys, in red, respectively located at altitudes 1, 3 and 3

Typical

$|$VARIABLES$| \geq 7$
range(VARIABLES.var) > 1
VALLEY(VARIABLES.var) ≥ 3

Typical model

nval(VARIABLES.var) > 2

Symmetry

One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Counting

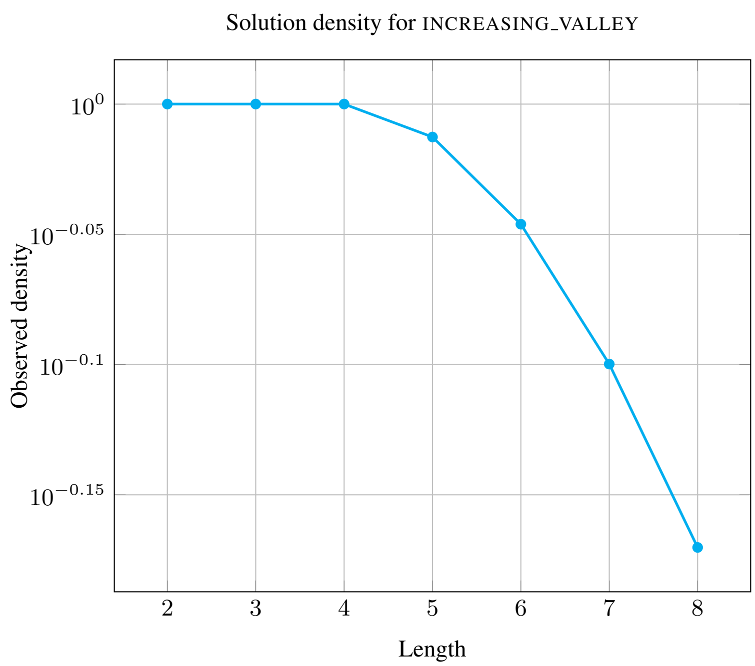
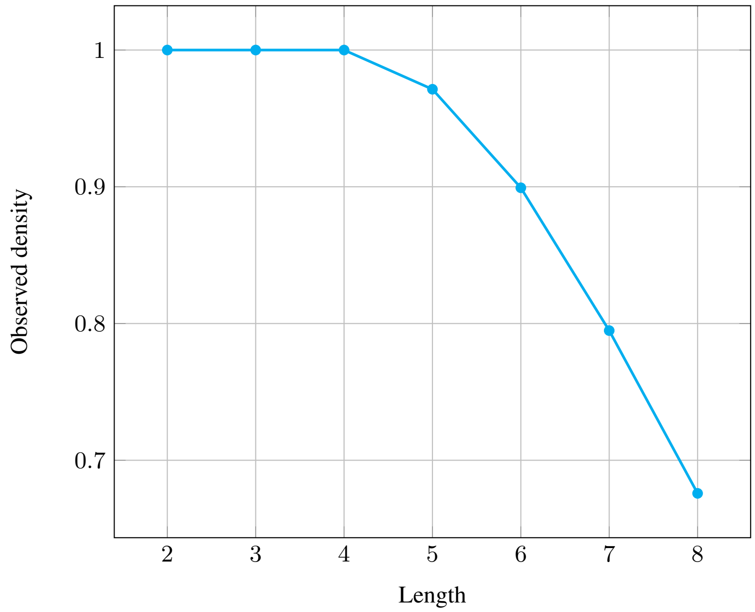
Number of solutions for INCREASING_VALLEY: domains $0..n$



Solution density for INCREASING_VALLEY



See also **implied by:** ALL_EQUAL_VALLEY.

related: DECREASING_VALLEY, VALLEY.

Keywords **characteristic of a constraint:** automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint network structure: sliding cyclic(1) constraint network(2).

Cond. implications INCREASING_VALLEY(VARIABLES)
with VALLEY(VARIABLES.var) > 0
implies NOT_ALL_EQUAL(VARIABLES).

Automaton Figure 5.450 depicts the automaton associated with the INCREASING_VALLEY constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $(\mathtt{VAR}_i < \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 0) \wedge (\mathtt{VAR}_i = \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 1) \wedge (\mathtt{VAR}_i > \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 2)$.

STATE SEMANTICS

s	: initial stationary or increasing mode	$(\{= \mid <\}^*)$
u	: decreasing (before first potential valley) mode	$(> \{> \mid =\}^*)$
v	: increasing (after a valley) mode	$(< \{< \mid =\}^*)$
w	: decreasing (after a valley) mode	$(> \{> \mid =\}^*)$

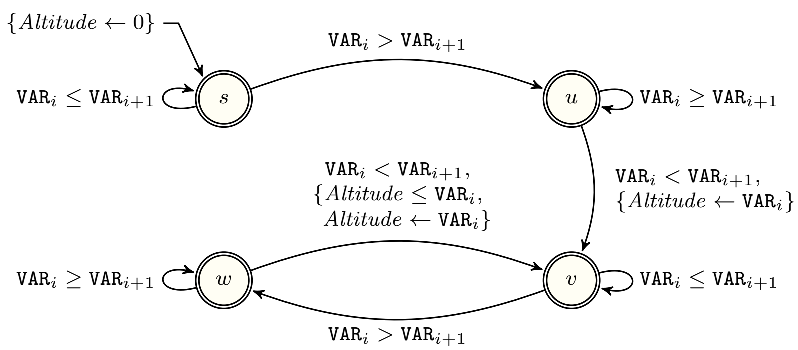


Figure 5.450: Automaton for the INCREASING_VALLEY constraint (note the conditional transition from state w to state v testing that the counter $Altitude$ is less than or equal to $\mathtt{VAR}_i$ for enforcing that all valleys from left to right are in increasing altitude)

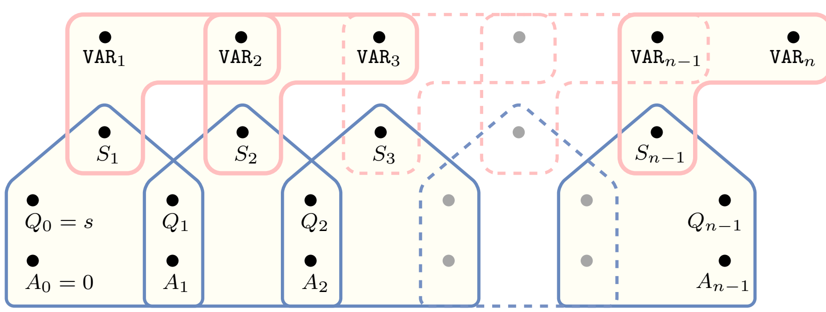

Figure 5.451: Hypergraph of the reformulation corresponding to the automaton of the INCREASING_VALLEY constraint where A_i stands for the value of the counter $Altitude$ (since all states of the automaton are accepting there is no restriction on the last variable Q_{n-1})

5.194 INDEXED_SUM

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint INDEXED_SUM(ITEMS, TABLE)

Arguments

ITEMS : collection(index−dvar, weight−dvar)
TABLE : collection(index−int, summation−dvar)

Restrictions

$|\mathtt{ITEMS}| > 0$
$|\mathtt{TABLE}| > 0$
required(ITEMS, [index, weight])
ITEMS.index ≥ 1
ITEMS.index $\leq |\mathtt{TABLE}|$
required(TABLE, [index, summation])
TABLE.index ≥ 1
TABLE.index $\leq |\mathtt{TABLE}|$
increasing_seq(TABLE, index)

Purpose

Given several items of the collection ITEMS (each of them having a specific fixed index as well as a weight that may be negative or positive), and a table TABLE (each entry of TABLE corresponding to a summation variable), assign each item to an entry of TABLE so that the sum of the weights of the items assigned to that entry is equal to the corresponding summation variable.

Example

$$\left(\begin{array}{l}\left\langle\begin{array}{ll}\mathtt{index}-3 & \mathtt{weight}-{-4},\\ \mathtt{index}-1 & \mathtt{weight}-6,\\ \mathtt{index}-3 & \mathtt{weight}-1\end{array}\right\rangle,\\ \left\langle\begin{array}{ll}\mathtt{index}-1 & \mathtt{summation}-6,\\ \mathtt{index}-2 & \mathtt{summation}-0,\\ \mathtt{index}-3 & \mathtt{summation}-{-3}\end{array}\right\rangle\end{array}\right)$$

The INDEXED_SUM constraint holds since the summation variables associated with each entry of TABLE are equal to the sum of the weights of the items assigned to the corresponding entry:

- TABLE[1].summation $=$ ITEMS[2].weight $= 6$ (since TABLE[1].index $=$ ITEMS[2].index $= 1$),
- TABLE[2].summation $= 0$ (since TABLE[2].index $= 2$ does not occur as a value of the index attribute of an item of ITEMS),
- TABLE[3].summation $=$ ITEMS[1].weight $+$ ITEMS[3].weight $= -4 + 1 = -3$ (since TABLE[3].index $=$ ITEMS[1].index $=$ ITEMS[3].index $= 3$).

Typical

$|\texttt{ITEMS}| > 1$
$\texttt{range}(\texttt{ITEMS.index}) > 1$
$|\texttt{TABLE}| > 1$
$\texttt{range}(\texttt{TABLE.summation}) > 1$

Symmetries

- Items of ITEMS are permutable.
- Items of TABLE are permutable.

Reformulation

The INDEXED_SUM(ITEMS, TABLE) constraint can be expressed in term of a set of reified constraints and of $|\texttt{TABLE}|$ arithmetic constraints (i.e., SCALAR_PRODUCT constraints).

1. For each item $\texttt{ITEMS}[i]$ ($i \in [1, |\texttt{ITEMS}|]$) and for each table entry j ($j \in [1, |\texttt{TABLE}|]$) of TABLE we create a 0-1 variable B_{ij} that will be set to 1 if and only if $\texttt{ITEMS}[i].\texttt{index}$ is fixed to j (i.e., $B_{ij} \Leftrightarrow \texttt{ITEMS}[i].\texttt{index} = j$).
2. For each entry j of the table TABLE, we impose the sum $\texttt{ITEMS}[1].\texttt{weight} \cdot B_{1j} + \texttt{ITEMS}[2].\texttt{weight} \cdot B_{2j} + \cdots + \texttt{ITEMS}[|\texttt{ITEMS}|].\texttt{weight} \cdot B_{|\texttt{ITEMS}|j}$ to be equal to $\texttt{TABLE}[j].\texttt{summation}$.

See also

implied by: ELEMENTS_ALLDIFFERENT.

specialisation: BIN_PACKING *(negative contribution not allowed, effective use variable for each bin replaced by an overall fixed capacity)*, BIN_PACKING_CAPA *(negative contribution not allowed, effective use variable for each bin replaced by a fixed capacity for each bin)*.

used in graph description: SUM_CTR.

Keywords

application area: assignment.

modelling: variable indexing, variable subscript.

For all items of TABLE:

Arc input(s)	ITEMS TABLE
Arc generator	$PRODUCT \mapsto$ collection(items, table)
Arc arity	2
Arc constraint(s)	items.index = table.index
Sets	SUCC $\mapsto$ [source, variables − col (VARIABLES−collection(var−dvar), [item(var − ITEMS.weight)])]
Constraint(s) on sets	SUM_CTR(variables, =, TABLE.summation)

Graph model We enforce the SUM_CTR constraint on the weight of the items that are assigned to the same entry. Within the context of the **Example** slot, part (A) of Figure 5.452 shows the initial graphs associated with entries 1, 2 and 3 (i.e., one initial graph for each item of the TABLE collection). Part (B) of Figure 5.452 shows the corresponding final graphs associated with entries 1 and 3. Each source vertex of the final graph can be interpreted as an item assigned to a specific entry of TABLE.

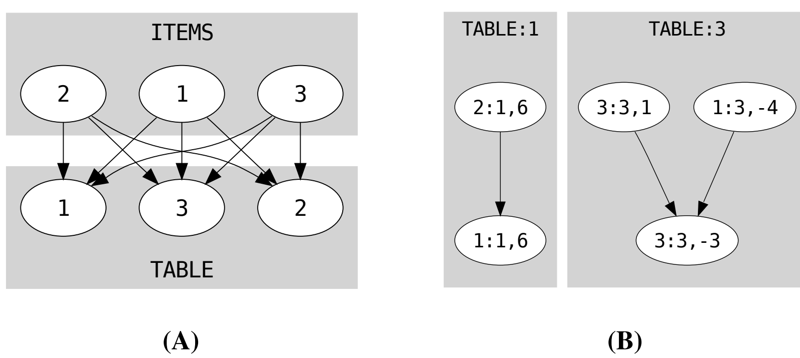

Figure 5.452: Initial and final graph of the INDEXED_SUM constraint

5.195 INFLEXION

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin N. Beldiceanu

Constraint INFLEXION(N, VARIABLES)

Arguments

N : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\text{N} \geq 0$
$\text{N} \leq \max(0, |\text{VARIABLES}| - 2)$
required(VARIABLES, var)

Purpose

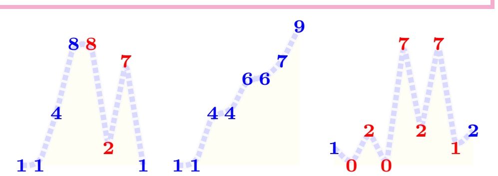
N is equal to the number of times that the following conjunctions of constraints hold:

- X_i CTR $X_{i+1} \wedge X_i \neq X_{i+1}$,
- $X_{i+1} = X_{i+2} \wedge \cdots \wedge X_{j-2} = X_{j-1}$,
- $X_{j-1} \neq X_j \wedge X_{j-1}$ ¬CTR X_j.

where X_k is the k^{th} item of the VARIABLES collection and $1 \leq i, i+2 \leq j, j \leq n$ and CTR is $<$ or $>$.

Example

(3, ⟨1, 1, 4, 8, 8, 2, 7, 1⟩)
(0, ⟨1, 1, 4, 4, 6, 6, 7, 9⟩)
(7, ⟨1, 0, 2, 0, 7, 2, 7, 1, 2⟩)



The first INFLEXION constraint holds since the sequence 1 1 4 8 8 2 7 1 contains three inflexions peaks that respectively correspond to values 8, 2 and 7.

All solutions

Figure 5.454 gives all solutions to the following non ground instance of the INFLEXION constraint: $\text{N} \in \{0, 2\}$, $\text{V}_1 = 2$, $\text{V}_2 \in [2, 3]$, $\text{V}_3 \in [1, 2]$, $\text{V}_4 \in [1, 2]$, $\text{V}_5 = 3$, INFLEXION(N, ⟨$\text{V}_1, \text{V}_2, \text{V}_3, \text{V}_4, \text{V}_5$⟩).

Typical

$\text{N} > 0$
$|\text{VARIABLES}| > 2$
range(VARIABLES.var) > 1

Typical model

nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Functional dependency: N determined by VARIABLES.

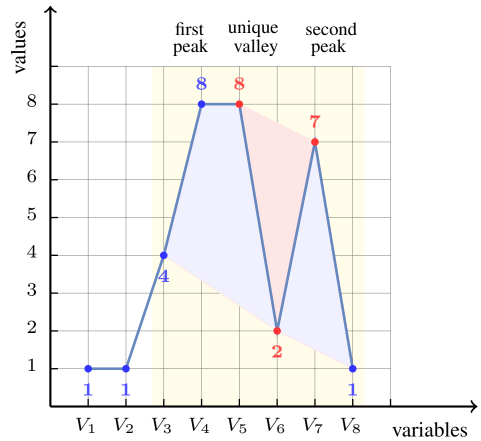


Figure 5.453: Illustration of the first example of the **Example** slot: a sequence of eight variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8 respectively fixed to values $1, 1, 4, 8, 8, 2, 7, 1$ and its three inflexions in red, two peaks and one valley ($\mathtt{N} = 3$)

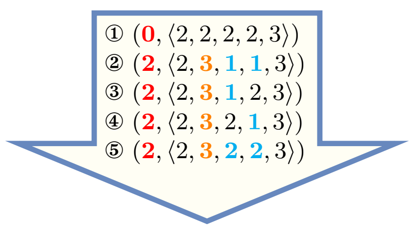

Figure 5.454: All solutions corresponding to the non ground example of the INFLEXION constraint of the **All solutions** slot where each inflexion (i.e. peak or valley) is coloured in orange or cyan

Usage

Useful for constraining the number of *inflexions* of a sequence of domain variables.

Remark

Since the arity of the arc constraint is not fixed, the INFLEXION constraint cannot be currently described with the graph-based representation. However, this would not hold anymore if we were introducing a slot that specifies how to merge adjacent vertices of the final graph.

5.196 INSIDE_SBOXES

DESCRIPTION LINKS LOGIC

Origin Geometry, derived from [349]

Constraint INSIDE_SBOXES(K, DIMS, OBJECTS, SBOXES)

Synonym INSIDE.

Types

VARIABLES	:	collection(v−dvar)
INTEGERS	:	collection(v−int)
POSITIVES	:	collection(v−int)

Arguments

K	:	int
DIMS	:	sint
OBJECTS	:	collection(oid−int, sid−dvar, x − VARIABLES)
SBOXES	:	collection(sid−int, t − INTEGERS, l − POSITIVES)

Restrictions

$|\mathtt{VARIABLES}| \geq 1$
$|\mathtt{INTEGERS}| \geq 1$
$|\mathtt{POSITIVES}| \geq 1$
required(VARIABLES, v)
$|\mathtt{VARIABLES}| = \mathtt{K}$
required(INTEGERS, v)
$|\mathtt{INTEGERS}| = \mathtt{K}$
required(POSITIVES, v)
$|\mathtt{POSITIVES}| = \mathtt{K}$
$\mathtt{POSITIVES.v} > 0$
$\mathtt{K} > 0$
$\mathtt{DIMS} \geq 0$
$\mathtt{DIMS} < \mathtt{K}$
increasing_seq(OBJECTS, [oid])
required(OBJECTS, [oid, sid, x])
$\mathtt{OBJECTS.oid} \geq 1$
$\mathtt{OBJECTS.oid} \leq |\mathtt{OBJECTS}|$
$\mathtt{OBJECTS.sid} \geq 1$
$\mathtt{OBJECTS.sid} \leq |\mathtt{SBOXES}|$
$|\mathtt{SBOXES}| \geq 1$
required(SBOXES, [sid, t, l])
$\mathtt{SBOXES.sid} \geq 1$
$\mathtt{SBOXES.sid} \leq |\mathtt{SBOXES}|$
do_not_overlap(SBOXES)

Purpose

Holds if, for each pair of objects (O_i, O_j), $i < j$, O_i is inside O_j with respect to a set of dimensions depicted by `DIMS`. O_i and O_j are objects that take a shape among a set of shapes. Each *shape* is defined as a finite set of shifted boxes, where each shifted box is described by a box in a `K`-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a *shifted box* is an entity defined by its shape id `sid`, shift offset `t`, and sizes `l`. Then, a shape is defined as the union of shifted boxes sharing the same shape id. An *object* is an entity defined by its unique object identifier `oid`, shape id `sid` and origin `x`.

An object O_i *is inside* an object O_j with respect to a set of dimensions depicted by `DIMS` if and only if, for all shifted boxes s_i associated with O_i, there exists a shifted box s_j of O_j such that s_j is inside s_i. A shifted box s_j *is inside* a shifted box s_i if and only if, for all dimensions $d \in$ `DIMS`, (1) the start of s_j in dimension d is strictly less than the start of s_i in dimension d, and (2) the end of s_i in dimension d is strictly less than the end of s_j in dimension d.

Example

$$\left(\begin{array}{l} 2, \{0,1\}, \\ \left\langle\begin{array}{lll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 3,3\rangle, \\ \texttt{oid}-2 & \texttt{sid}-2 & \texttt{x}-\langle 2,2\rangle, \\ \texttt{oid}-3 & \texttt{sid}-3 & \texttt{x}-\langle 1,1\rangle \end{array}\right\rangle, \\ \left\langle\begin{array}{lll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 3,3\rangle, \\ \texttt{sid}-3 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 5,5\rangle \end{array}\right\rangle \end{array}\right)$$

Figure 5.459 shows the objects of the example. Since O_1 is inside O_2 and O_3, and since O_2 is also inside O_3, the INSIDE_SBOXES constraint holds.

Typical

$|\texttt{OBJECTS}| > 1$

Symmetries

- Items of `SBOXES` are permutable.
- Items of `OBJECTS.x`, `SBOXES.t` and `SBOXES.l` are permutable (*same permutation used*).

Arg. properties

Suffix-contractible wrt. `OBJECTS`.

Remark

One of the eight relations of the *Region Connection Calculus* [349]. The constraint INSIDE_SBOXES is a restriction of the original relation since it requires that each box of an object is contained by one box of the other object.

5.197 INT_VALUE_PRECEDE

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin [269]

Constraint INT_VALUE_PRECEDE(S, T, VARIABLES)

Synonyms PRECEDE, PRECEDENCE, VALUE_PRECEDE.

Arguments

S	:	int
T	:	int
VARIABLES	:	collection(var−dvar)

Restrictions

$\mathtt{S} \neq \mathtt{T}$
required(VARIABLES, var)

Purpose If value T occurs in the collection of variables VARIABLES then its first occurrence should be preceded by an occurrence of value S.

Example $(0, 1, \langle 4, 0, 6, 1, 0\rangle)$

The INT_VALUE_PRECEDE constraint holds since the first occurrence of value 0 precedes the first occurrence of value 1.

Typical

$\mathtt{S} < \mathtt{T}$
$|\mathtt{VARIABLES}| > 1$
ATLEAST(1, VARIABLES, S)
ATLEAST(1, VARIABLES, T)

Symmetries

- An occurrence of a value of VARIABLES.var that is different from S and T can be replaced by any other value that is also different from S and T.
- All occurrences of values S and T can be swapped in S, T and VARIABLES.var.

Arg. properties

- Suffix-contractible wrt. VARIABLES.
- Aggregate: S(id), T(id), VARIABLES(union).

Algorithm A filtering algorithm for maintaining value precedence is presented in [269]. Its complexity is linear to the number of variables of the collection VARIABLES.

Systems PRECEDE in **Gecode**, VALUE_PRECEDE in **MiniZinc**.

See also **generalisation:** INT_VALUE_PRECEDE_CHAIN *(*sequence *of* 2 values *replaced by* sequence *of at least* 2 values*)*, SET_VALUE_PRECEDE *(*sequence *of* domain variables *replaced by* sequence *of* set variables*)*.

Keywords

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: order constraint.

filtering: arc-consistency.

symmetry: symmetry, indistinguishable values, value precedence.

Automaton Figure 5.460 depicts the automaton associated with the INT_VALUE_PRECEDE constraint. Let $\mathtt{VAR}_i$ be the i^{th} variable of the VARIABLES collection. To each triple $(\mathtt{S}, \mathtt{T}, \mathtt{VAR}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\mathtt{VAR}_i = \mathtt{S} \Leftrightarrow S_i = 1) \wedge (\mathtt{VAR}_i = \mathtt{T} \Leftrightarrow S_i = 2) \wedge (\mathtt{VAR}_i \neq \mathtt{S} \wedge \mathtt{VAR}_i \neq \mathtt{T} \Leftrightarrow S_i = 3)$.

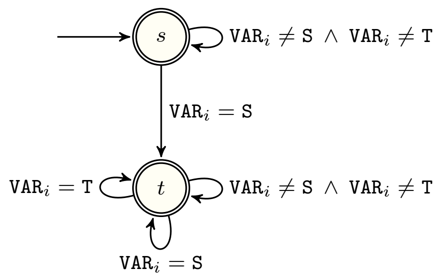

Figure 5.460: Automaton of the INT_VALUE_PRECEDE constraint (state s means that value S was not yet encountered, while state t means that value S was already encountered)

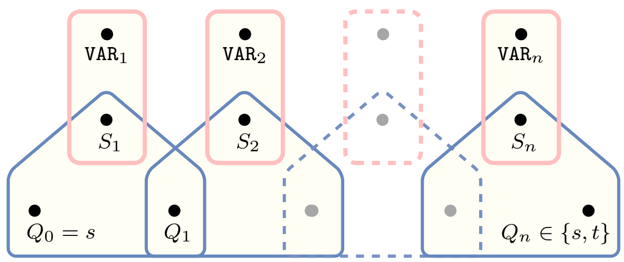

Figure 5.461: Hypergraph of the reformulation corresponding to the automaton of the INT_VALUE_PRECEDE constraint

5.198 INT_VALUE_PRECEDE_CHAIN

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin [269]

Constraint INT_VALUE_PRECEDE_CHAIN(VALUES, VARIABLES)

Synonyms PRECEDE, PRECEDENCE, VALUE_PRECEDE_CHAIN.

Arguments

VALUES	:	collection(var−int)
VARIABLES	:	collection(var−dvar)

Restrictions

required(VALUES, var)
distinct(VALUES, var)
required(VARIABLES, var)

Purpose Assuming n denotes the number of items of the VALUES collection, the following condition holds for every $i \in [1, n-1]$: When it is defined, the first occurrence of the $(i+1)^{th}$ value of the VALUES collection should be preceded by the first occurrence of the i^{th} value of the VALUES collection.

Example $(\langle 4,0,1\rangle, \langle 4,0,6,1,0\rangle)$

The INT_VALUE_PRECEDE_CHAIN constraint holds since within the sequence 4, 0, 6, 1, 0:

- The first occurrence of value 4 occurs before the first occurrence of value 0.
- The first occurrence of value 0 occurs before the first occurrence of value 1.

Typical

$|\mathtt{VALUES}| > 1$
STRICTLY_INCREASING(VALUES)
$|\mathtt{VARIABLES}| > |\mathtt{VALUES}|$
range(VARIABLES.var) > 1
USED_BY(VARIABLES, VALUES)

Symmetry An occurrence of a value of VARIABLES.var that does not occur in VALUES.var can be replaced by any other value that also does not occur in VALUES.var.

Arg. properties

- Contractible wrt. VALUES.
- Suffix-contractible wrt. VARIABLES.
- Aggregate: VALUES(id), VARIABLES(union).

Usage The INT_VALUE_PRECEDE_CHAIN constraint is useful for breaking symmetries in graph colouring problems. We set a INT_VALUE_PRECEDE_CHAIN constraint on all variables $V_1, V_2, \ldots, V_n$ associated with the vertices of the graph to colour, where we state that the first occurrence of colour i should be located before the first occurrence of colour $i+1$ within the sequence $V_1, V_2, \ldots, V_n$.

Figure 5.462 illustrates the problem of *colouring earth and mars* from Thom Sulanke. Part (A) of Figure 5.462 provides a solution where the first occurrence of each value of i, ($i \in \{1, 2, \ldots, 8\}$) is located before the first occurrence of value $i+1$. This is obtained by using the following constraints:

$$\left\{\begin{array}{l}
\mathtt{A} \neq \mathtt{B}, \mathtt{A} \neq \mathtt{E}, \mathtt{A} \neq \mathtt{F}, \mathtt{A} \neq \mathtt{G}, \mathtt{A} \neq \mathtt{H}, \mathtt{A} \neq \mathtt{I}, \mathtt{A} \neq \mathtt{J}, \mathtt{A} \neq \mathtt{K},\\
\mathtt{B} \neq \mathtt{A}, \mathtt{B} \neq \mathtt{C}, \mathtt{B} \neq \mathtt{F}, \mathtt{B} \neq \mathtt{G}, \mathtt{B} \neq \mathtt{H}, \mathtt{B} \neq \mathtt{I}, \mathtt{B} \neq \mathtt{J}, \mathtt{B} \neq \mathtt{K},\\

\mathtt{I} \neq \mathtt{A}, \mathtt{I} \neq \mathtt{B}, \mathtt{I} \neq \mathtt{C}, \mathtt{I} \neq \mathtt{D}, \mathtt{I} \neq \mathtt{E}, \mathtt{I} \neq \mathtt{F}, \mathtt{I} \neq \mathtt{G}, \mathtt{I} \neq \mathtt{H}, \mathtt{I} \neq \mathtt{J}, \mathtt{I} \neq \mathtt{K},\\
\mathtt{J} \neq \mathtt{A}, \mathtt{J} \neq \mathtt{B}, \mathtt{J} \neq \mathtt{C}, \mathtt{J} \neq \mathtt{D}, \mathtt{J} \neq \mathtt{E}, \mathtt{J} \neq \mathtt{F}, \mathtt{J} \neq \mathtt{G}, \mathtt{J} \neq \mathtt{H}, \mathtt{J} \neq \mathtt{I}, \mathtt{J} \neq \mathtt{K},\\
\mathtt{K} \neq \mathtt{A}, \mathtt{K} \neq \mathtt{B}, \mathtt{K} \neq \mathtt{C}, \mathtt{K} \neq \mathtt{D}, \mathtt{K} \neq \mathtt{E}, \mathtt{K} \neq \mathtt{F}, \mathtt{K} \neq \mathtt{G}, \mathtt{K} \neq \mathtt{H}, \mathtt{K} \neq \mathtt{I}, \mathtt{K} \neq \mathtt{J},\\
\text{INT_VALUE_PRECEDE_CHAIN}(\langle 1,2,3,4,5,6,7,8,9\rangle, \langle \mathtt{A},\mathtt{B},\mathtt{C},\mathtt{D},\mathtt{E},\mathtt{F},\mathtt{G},\mathtt{H},\mathtt{I},\mathtt{J},\mathtt{K}\rangle).
\end{array}\right.$$

Part (B) provides a symmetric solution where the value precedence constraints between the pairs of values $(1, 2)$, $(2, 3)$, $(4, 5)$, $(7, 8)$ and $(8, 9)$ are all violated (each violation is depicted by a dashed arc).

For one other example of use of the INT_VALUE_PRECEDE_CHAIN constraint in the context of bin packing problems see the exercise called switching time and resource and breaking symmetry of the CUMULATIVE constraint.

Remark When we have more than one class of interchangeable values (i.e., a partition of interchangeable values) we can use one INT_VALUE_PRECEDE_CHAIN constraint for breaking value symmetry in each class of interchangeable values. However it was shown in [450] that enforcing arc-consistency for such a conjunction of INT_VALUE_PRECEDE_CHAIN constraints is NP-hard.

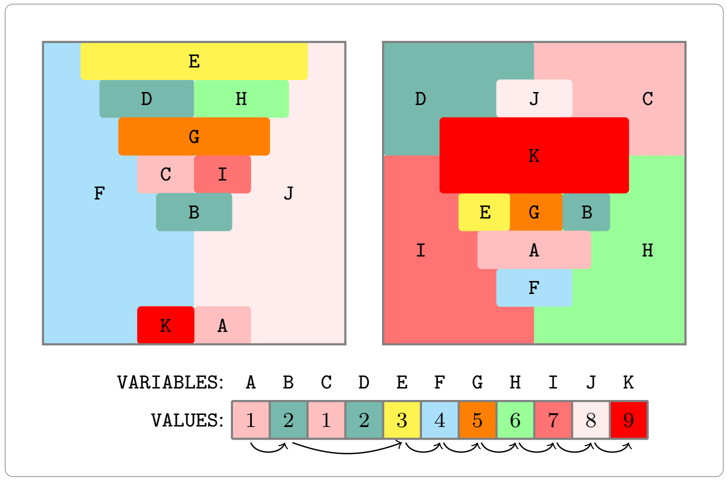
Algorithm The 2004 reformulation [30] associated with the automaton of the **Automaton** slot achieves arc-consistency since the corresponding constraint network is a Berge-acyclic constraint network. Later on, another formulation into a sequence of ternary sliding constraints was proposed by [449]. It also achieves arc-consistency for the same reason.

Systems PRECEDE in **Gecode**, VALUE_PRECEDE_CHAIN in **MiniZinc**.

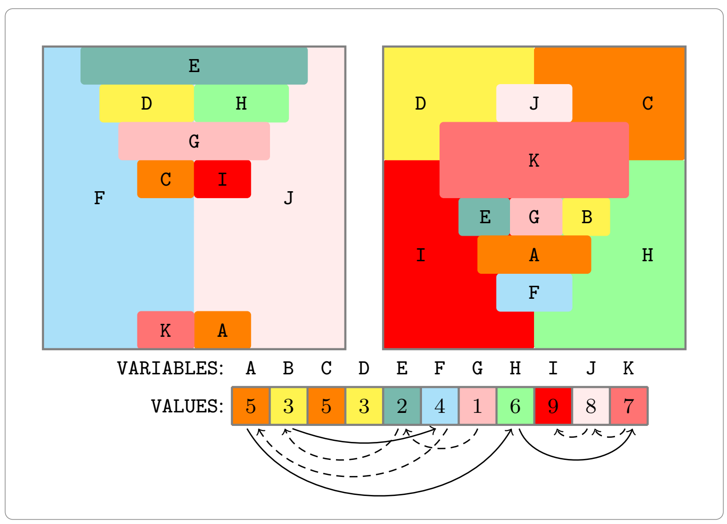
See also **specialisation:** INT_VALUE_PRECEDE *(*`sequence` *of at least* 2 `values` *replaced by* `sequence` *of* 2 `values`*)*.

Keywords **characteristic of a constraint:** automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.



(A) Chain of satisfied value precedences between first occurrence of consecutive values



(B) Broken value precedences between first occurrence of consecutive values (in dashed)

Figure 5.462: Using the INT_VALUE_PRECEDE_CHAIN constraint for breaking symmetries in graph colouring problems; there is an arc between the first occurrence of value v $(1 \leq v \leq 8)$ in the sequence of variables A, B, C, D, E, F, G, H, I, J, K, and the first occurrence of value $v+1$ (a plain arc if the corresponding value precedence constraint holds, a dashed arc otherwise)

constraint type: order constraint.

filtering: arc-consistency.

problems: graph colouring.

symmetry: symmetry, indistinguishable values, value precedence.

Automaton Figure 5.463 depicts the automaton associated with the INT_VALUE_PRECEDE_CHAIN constraint. Let n and m respectively denote the number of variables of the VARIABLES collection and the number of values of the VALUES collection. Let $\mathtt{VAR}_i$ be the i^{th} variable of the VARIABLES collection. Let $\mathtt{val}_v$ $(1 \leq v \leq m)$ denote the v^{th} value of the VALUES collection.

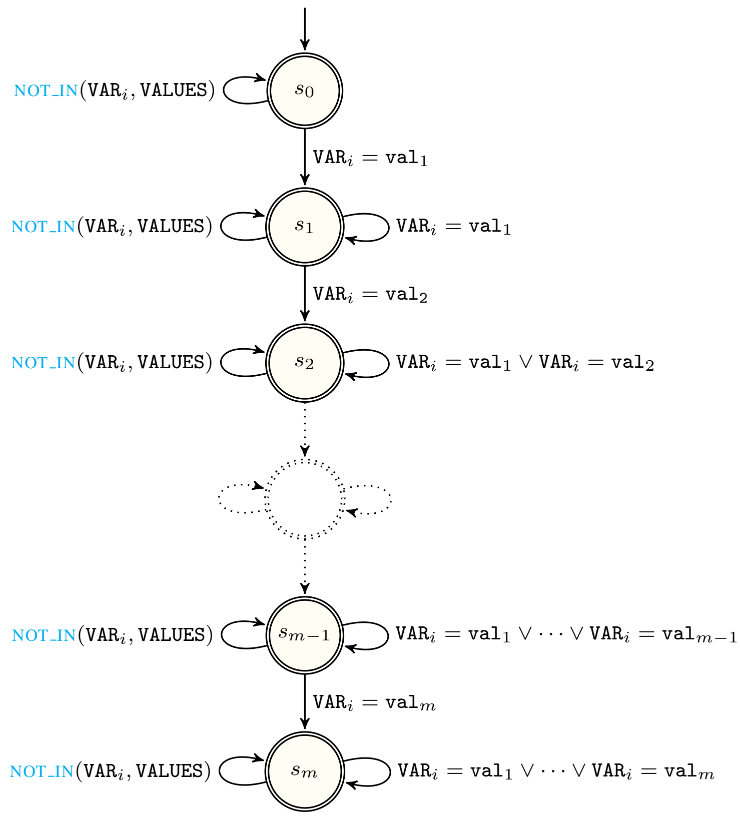


Figure 5.463: Automaton of the INT_VALUE_PRECEDE_CHAIN constraint (state s_i means that (1) each value $\mathtt{val}_1, \mathtt{val}_2, \ldots, \mathtt{val}_i$ was already encountered at least once, and that (2) value $\mathtt{val}_{i+1}$ was not yet found)

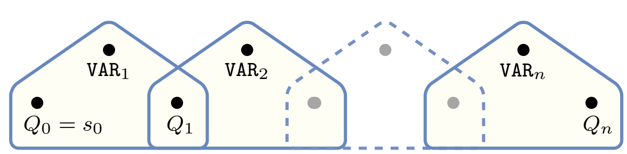

Figure 5.464: Hypergraph of the reformulation corresponding to the automaton of the INT_VALUE_PRECEDE_CHAIN constraint (since all states of the automaton are accepting there is no restriction on the last variable Q_n)

We now show how to construct such an automaton systematically. For this purpose let us first introduce some notations:

- Without loss of generality we assume that we have at least two values (i.e., $m \geq 2$).
- Let $\mathcal{C}$ be the set of values that can be potentially assigned to a variable of the `VARIABLES` collection, but which do not belong to the values of the `VALUES` collection (i.e., $\mathcal{C} = (dom(\mathtt{VAR}_1) \cup dom(\mathtt{VAR}_2) \cup \cdots \cup dom(\mathtt{VAR}_n) - \{\mathtt{val}_1, \mathtt{val}_2, \ldots, \mathtt{val}_m\} = \{w_1, w_2, \ldots, w_{|\mathcal{C}|}\}$.

The states and transitions of the automaton are respectively defined in the following way:

- We have $m+1$ states labelled $s_0, s_1, \ldots, s_m$ from which s_0 is the initial state. All states are accepting states.
- We have the following three sets of transitions:
  1. For all $v \in [0, m-1]$, a transition from s_v to s_{v+1} labelled by value $\mathtt{val}_{v+1}$. Each transition of this type will be triggered on the first occurrence of value $\mathtt{val}_{v+1}$ within the variables of the `VARIABLES` collection.
  2. For all $v \in [1, m]$ and for all $w \in [1, v]$, a self loop on s_v labelled by value $\mathtt{val}_w$. Such transitions encode the fact that we stay in the same state as long as we have a value that was already encountered.
  3. If the set $\mathcal{C}$ is not empty, then for all $v \in [0, m]$ a self loop on s_v labelled by the fact that we take a value not in `VALUES` (i.e., a value in $\mathcal{C}$). This models the fact that, encountering a value that does not belong to the set of values of the `VALUES` collection, leaves us in the same state.

5.199 INTERVAL_AND_COUNT

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin [135]

Constraint INTERVAL_AND_COUNT(ATMOST, COLOURS, TASKS, SIZE_INTERVAL)

Arguments

ATMOST	:	int
COLOURS	:	collection(val−int)
TASKS	:	collection(origin−dvar, colour−dvar)
SIZE_INTERVAL	:	int

Restrictions

ATMOST ≥ 0
required(COLOURS, val)
distinct(COLOURS, val)
required(TASKS, [origin, colour])
TASKS.origin ≥ 0
SIZE_INTERVAL > 0

Purpose

First consider the set of tasks of the TASKS collection, where each task has a specific colour that may not be initially fixed. Then consider the intervals of the form $[k \cdot \texttt{SIZE\_INTERVAL}, k \cdot \texttt{SIZE\_INTERVAL} + \texttt{SIZE\_INTERVAL} - 1]$, where k is an integer. The INTERVAL_AND_COUNT constraint forces that, for each interval I_k previously defined, the total number of tasks, which both are assigned to I_k and take their colours in COLOURS, does not exceed the limit ATMOST.

Example

$$\left(\begin{array}{l} 2, \langle 4 \rangle, \\ \left\langle \begin{array}{ll} \texttt{origin}-1 & \texttt{colour}-4, \\ \texttt{origin}-0 & \texttt{colour}-9, \\ \texttt{origin}-10 & \texttt{colour}-4, \\ \texttt{origin}-4 & \texttt{colour}-4 \end{array} \right\rangle, 5 \end{array}\right)$$

Figure 5.465 shows the solution associated with the example. The constraint INTERVAL_AND_COUNT holds since, for each interval, the number of tasks taking colour 4 does not exceed the limit 2.

Typical

ATMOST > 0
ATMOST $<$ |TASKS|
|COLOURS| > 0
|TASKS| > 1
range(TASKS.origin) > 1
range(TASKS.colour) > 1
SIZE_INTERVAL > 1

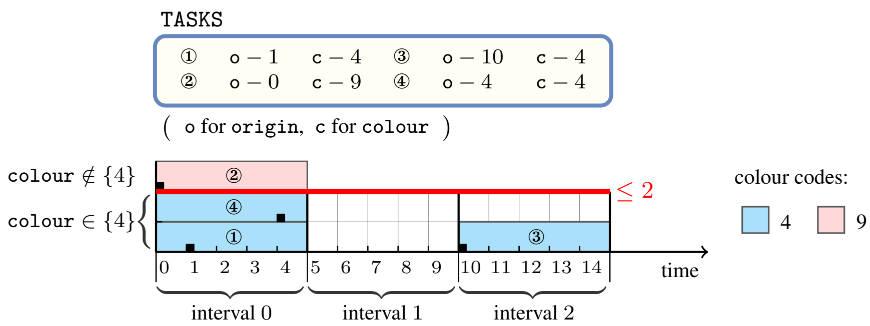

Figure 5.465: The INTERVAL_AND_COUNT solution to the **Example** slot with the use of each interval

Symmetries

- ATMOST can be increased.
- Items of COLOURS are permutable.
- Items of TASKS are permutable.
- One and the same constant can be added to the origin attribute of all items of TASKS.
- An occurrence of a value of TASKS.origin that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.
- An occurrence of a value of TASKS.colour that belongs to COLOURS.val (resp. does not belong to COLOURS.val) can be replaced by any other value in COLOURS.val (resp. not in COLOURS.val).

Arg. properties

- Contractible wrt. COLOURS.
- Contractible wrt. TASKS.

Usage This constraint was originally proposed for dealing with timetabling problems. In this context the different intervals are interpreted as morning and afternoon periods of different consecutive days. Each colour corresponds to a type of course (i.e., French, mathematics). There is a restriction on the maximum number of courses of a given type each morning as well as each afternoon.

Remark If we want to only consider intervals that correspond to the morning or to the afternoon we could extend the INTERVAL_AND_COUNT constraint in the following way:

- We introduce two extra parameters REST and QUOTIENT that correspond to non-negative integers such that REST is strictly less than QUOTIENT,
- We add the following condition to the arc constraint: $(\texttt{tasks1.origin}/\texttt{SIZE\_INTERVAL}) \equiv \texttt{REST}(\bmod \texttt{QUOTIENT})$

Now, if we want to express a constraint on the morning intervals, we set REST to 0 and QUOTIENT to 2.

Reformulation Let K denote the index of the last possible interval where the tasks can be assigned: $K = \lfloor \frac{\max_{i\in[1,|\texttt{TASKS}|]}(\texttt{TASKS}[i].\texttt{origin})+\texttt{SIZE\_INTERVAL}-1}{\texttt{SIZE\_INTERVAL}} \rfloor$. The

INTERVAL_AND_COUNT(ATMOST, COLOURS, TASKS, SIZE_INTERVAL) constraint can be expressed in term of a set of reified constraints and of K arithmetic constraints (i.e., SUM_CTR constraints).

1. For each task TASKS$[i]$ ($i \in [1, |\texttt{TASKS}|]$) of the TASKS collection we create a 0-1 variable B_i that will be set to 1 if and only if task TASKS$[i]$ takes a colour within the set of colours COLOURS:
$B_i \Leftrightarrow \texttt{TASKS}[i].\texttt{colour} = \texttt{COLOURS}[1].\texttt{val} \vee$
$\texttt{TASKS}[i].\texttt{colour} = \texttt{COLOURS}[2].\texttt{val} \vee$
$\dots\dots\dots\dots\dots\dots$
$\texttt{TASKS}[i].\texttt{colour} = \texttt{COLOURS}[|\texttt{COLOURS}|].\texttt{val}$.
2. For each task TASKS$[i]$ ($i \in [1, |\texttt{TASKS}|]$) and for each interval $[k \cdot \texttt{SIZE\_INTERVAL}, k \cdot \texttt{SIZE\_INTERVAL} + \texttt{SIZE\_INTERVAL} - 1]$ ($k \in [0, K]$) we create a 0-1 variable B_{ik} that will be set to 1 if and only if, both task TASKS$[i]$ takes a colour within the set of colours COLOURS, and the origin of task TASKS$[i]$ is assigned within interval $[k \cdot \texttt{SIZE\_INTERVAL}, k \cdot \texttt{SIZE\_INTERVAL} + \texttt{SIZE\_INTERVAL} - 1]$:
$B_{ik} \Leftrightarrow B_i \wedge$
$\texttt{TASKS}[i].\texttt{origin} \geq k \cdot \texttt{SIZE\_INTERVAL} \wedge$
$\texttt{TASKS}[i].\texttt{origin} \leq k \cdot \texttt{SIZE\_INTERVAL} + \texttt{SIZE\_INTERVAL} - 1$
3. Finally, for each interval $[k \cdot \texttt{SIZE\_INTERVAL}, k \cdot \texttt{SIZE\_INTERVAL} + \texttt{SIZE\_INTERVAL} - 1]$ ($k \in [0, K]$), we impose the sum $B_{1k} + B_{2k} + \cdots + B_{|\texttt{TASKS}|k}$ to not exceed the maximum allowed capacity ATMOST.

Arc input(s)	TASKS TASKS
Arc generator	$PRODUCT \mapsto$ collection(tasks1, tasks2)
Arc arity	2
Arc constraint(s)	tasks1.origin/SIZE_INTERVAL = tasks2.origin/SIZE_INTERVAL
Sets	SUCC $\mapsto$ [source, variables − col(VARIABLES−collection(var−dvar), [item(var − TASKS.colour)])]
Constraint(s) on sets	AMONG_LOW_UP(0, ATMOST, variables, COLOURS)

Graph model We use a bipartite graph where each class of vertices corresponds to the different tasks of the TASKS collection. There is an arc between two tasks if their origins belong to the same interval. Finally we enforce an AMONG_LOW_UP constraint on each set $\mathcal{S}$ of successors of the different vertices of the final graph. This put a restriction on the maximum number of tasks of $\mathcal{S}$ for which the colour attribute takes its value in COLOURS.

Parts (A) and (B) of Figure 5.466 respectively show the initial and final graph associated with the **Example** slot. Each connected component of the final graph corresponds to items that are all assigned to the same interval.

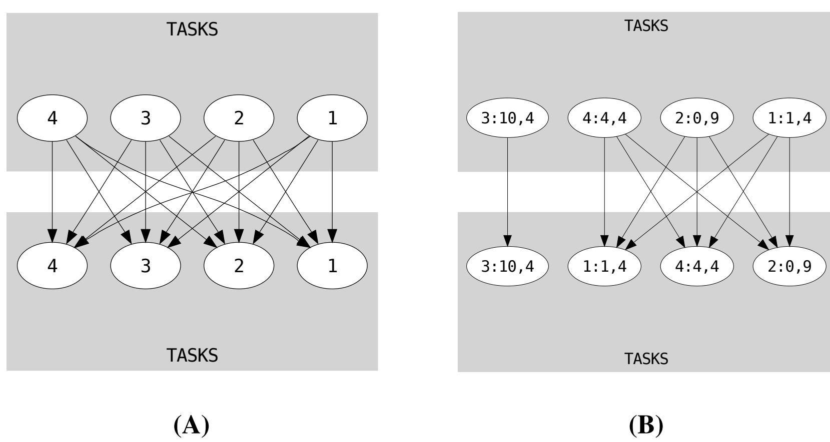

Figure 5.466: Initial and final graph of the INTERVAL_AND_COUNT constraint

Automaton Figure 5.467 depicts the automaton associated with the INTERVAL_AND_COUNT constraint. Let $\texttt{COLOUR}_i$ be the `colour` attribute of the i^{th} item of the `TASKS` collection. To each pair $(\texttt{COLOURS}, \texttt{COLOUR}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $\texttt{COLOUR}_i \in \texttt{COLOURS} \Leftrightarrow S_i$.

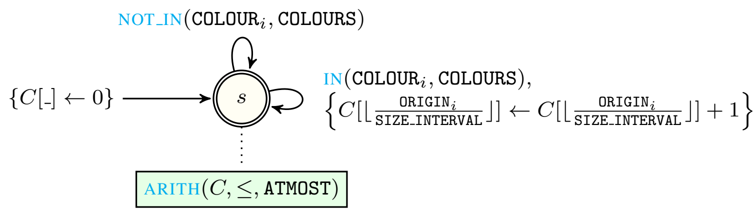

Figure 5.467: Automaton of the INTERVAL_AND_COUNT constraint

5.200 INTERVAL_AND_SUM

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Derived from CUMULATIVE.

Constraint INTERVAL_AND_SUM(SIZE_INTERVAL, TASKS, LIMIT)

Arguments

SIZE_INTERVAL	:	int
TASKS	:	collection(origin−dvar, height−dvar)
LIMIT	:	int

Restrictions

SIZE_INTERVAL > 0
required(TASKS, [origin, height])
TASKS.origin ≥ 0
TASKS.height ≥ 0
LIMIT ≥ 0

Purpose

A maximum resource capacity constraint: We have to fix the origins of a collection of tasks in such a way that, for all the tasks that are allocated to the same interval, the sum of the heights does not exceed a given capacity. All the intervals we consider have the following form: $[k \cdot \mathtt{SIZE\_INTERVAL}, k \cdot \mathtt{SIZE\_INTERVAL} + \mathtt{SIZE\_INTERVAL} - 1]$, where k is an integer.

Example

$$\left(5, \left\langle \begin{array}{ll} \mathtt{origin}-1 & \mathtt{height}-2, \\ \mathtt{origin}-10 & \mathtt{height}-2, \\ \mathtt{origin}-10 & \mathtt{height}-3, \\ \mathtt{origin}-4 & \mathtt{height}-1 \end{array} \right\rangle, 5\right)$$

Figure 5.468 shows the solution associated with the example. The constraint INTERVAL_AND_SUM holds since the sum of the heights of the tasks that are located in the same interval does not exceed the limit 5. Each task t is depicted by a rectangle r associated with the interval to which the task t is assigned. The rectangle r is labelled with the position of t within the items of the TASKS collection. The origin of task t is represented by a small black square located within its corresponding rectangle r. Finally, the height of a rectangle r is equal to the height of the task t to which it corresponds.

Typical

SIZE_INTERVAL > 1
$|\mathtt{TASKS}| > 1$
range(TASKS.origin) > 1
range(TASKS.height) > 1
LIMIT $<$ sum(TASKS.height)

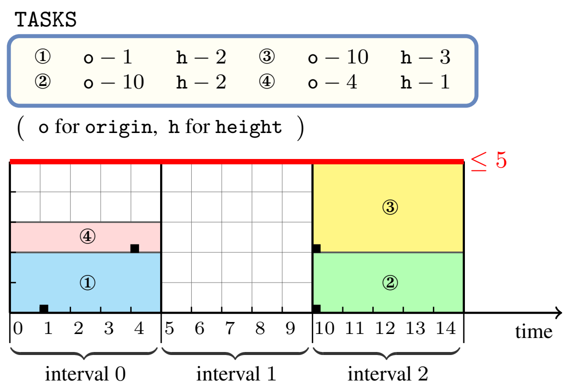

Figure 5.468: The INTERVAL_AND_SUM solution to the **Example** slot with the use of each interval

Symmetries

- Items of TASKS are permutable.
- One and the same constant can be added to the origin attribute of all items of TASKS.
- An occurrence of a value of TASKS.origin that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.
- TASKS.height can be decreased to any value ≥ 0.
- LIMIT can be increased.

Arg. properties

Contractible wrt. TASKS.

Usage

This constraint can be use for timetabling problems. In this context the different intervals are interpreted as morning and afternoon periods of different consecutive days. We have a capacity constraint for all tasks that are assigned to the same morning or afternoon of a given day.

Reformulation

Let K denote the index of the last possible interval where the tasks can be assigned: $K = \lfloor \frac{\max_{i\in[1,|\mathtt{TASKS}|]}(\overline{\mathtt{TASKS}[i].\mathtt{origin}})+\mathtt{SIZE\_INTERVAL}-1}{\mathtt{SIZE\_INTERVAL}} \rfloor$. The INTERVAL_AND_SUM(SIZE_INTERVAL, TASKS, LIMIT) constraint can be expressed in term of a set of reified constraints and of K arithmetic constraints (i.e., SCALAR_PRODUCT constraints).

1. For each task TASKS$[i]$ ($i \in [1, |\mathtt{TASKS}|]$) and for each interval $[k \cdot \mathtt{SIZE\_INTERVAL}, k \cdot \mathtt{SIZE\_INTERVAL} + \mathtt{SIZE\_INTERVAL} - 1]$ ($k \in [0, K]$) we create a 0-1 variable B_{ik} that will be set to 1 if and only if the origin of task TASKS$[i]$ is assigned within interval $[k \cdot \mathtt{SIZE\_INTERVAL}, k \cdot \mathtt{SIZE\_INTERVAL} + \mathtt{SIZE\_INTERVAL} - 1]$:
$B_{ik} \Leftrightarrow \mathtt{TASKS}[i].\mathtt{origin} \geq k \cdot \mathtt{SIZE\_INTERVAL} \wedge$
$\mathtt{TASKS}[i].\mathtt{origin} \leq k \cdot \mathtt{SIZE\_INTERVAL} + \mathtt{SIZE\_INTERVAL} - 1$
2. Finally, for each interval $[k \cdot \mathtt{SIZE\_INTERVAL}, k \cdot \mathtt{SIZE\_INTERVAL} + \mathtt{SIZE\_INTERVAL} - 1]$ ($k \in [0, K]$), we impose the sum $\mathtt{TASKS}[1].\mathtt{height} \cdot$

B_{1k} + TASKS[2].height $\cdot B_{2k} + \cdots +$ TASKS[|TASKS|].height $\cdot B_{|\mathtt{TASKS}|k}$ to not exceed the maximum allowed capacity LIMIT.

5.201 INVERSE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint INVERSE(NODES)

Synonyms ASSIGNMENT, CHANNEL, INVERSE_CHANNELING.

Argument NODES : collection(index−int, succ−dvar, pred−dvar)

Restrictions

required(NODES, [index, succ, pred])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ ≤ |NODES|
NODES.pred ≥ 1
NODES.pred ≤ |NODES|

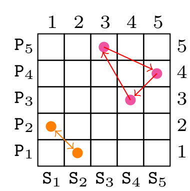
Purpose

Enforce each vertex of a digraph to have exactly one predecessor and one successor. In addition the following two statements are equivalent:

1. The successor of the i^{th} node is the j^{th} node.
2. The predecessor of the j^{th} node is the i^{th} node.

Example

$$\left(\left\langle\begin{array}{lll}\texttt{index}-1 & \texttt{succ}-2 & \texttt{pred}-2,\\ \texttt{index}-2 & \texttt{succ}-1 & \texttt{pred}-1,\\ \texttt{index}-3 & \texttt{succ}-5 & \texttt{pred}-4,\\ \texttt{index}-4 & \texttt{succ}-3 & \texttt{pred}-5,\\ \texttt{index}-5 & \texttt{succ}-4 & \texttt{pred}-3\end{array}\right\rangle\right)$$



The INVERSE constraint holds since:

- NODES[1].succ = 2 ⇔ NODES[2].pred = 1,
- NODES[2].succ = 1 ⇔ NODES[1].pred = 2,
- NODES[3].succ = 5 ⇔ NODES[5].pred = 3,
- NODES[4].succ = 3 ⇔ NODES[3].pred = 4,
- NODES[5].succ = 4 ⇔ NODES[4].pred = 5.

All solutions

Figure 5.471 gives all solutions to the following non ground instance of the INVERSE constraint: $S_1 \in [2,4]$, $P_1 \in [1,4]$, $S_2 \in [1,2]$, $P_2 \in [1,4]$, $S_3 \in [1,4]$, $P_3 \in [1,4]$, $S_4 \in [2,4]$, $P_4 \in [1,3]$, INVERSE(⟨1 S_1 P_1, 2 S_2 P_2, 3 S_3 P_3, 4 S_4 P_4⟩).

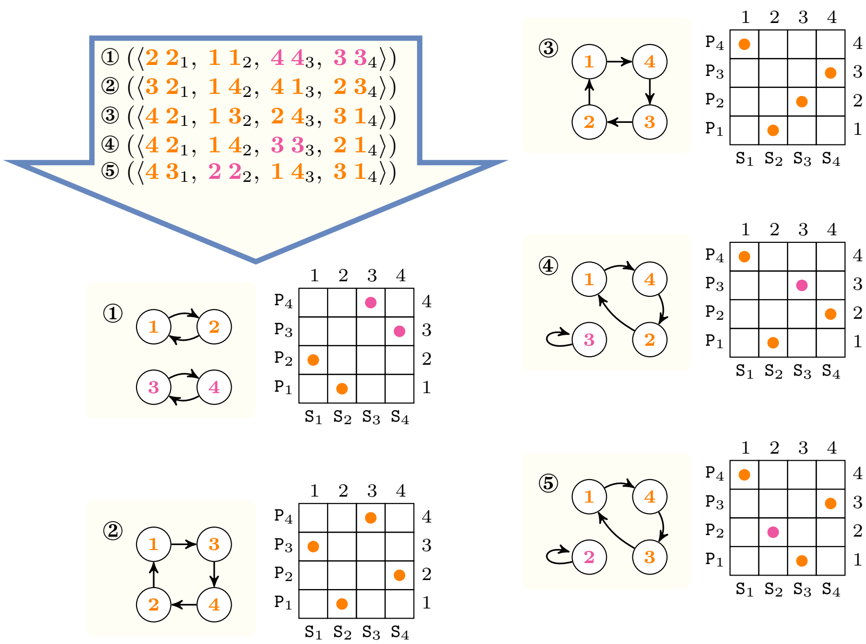


Figure 5.471: All solutions corresponding to the non ground example of the INVERSE constraint of the **All solutions** slot; in the left-hand side the `index` attributes are displayed as indices of the `pred` attribute, while in the right-hand side and in the lower part they are directly displayed within each node of the corresponding graph.

Typical $|\texttt{NODES}| > 1$

Symmetries

- Items of `NODES` are permutable.
- Attributes of `NODES` are permutable w.r.t. permutation (`index`) (`succ`, `pred`) (*permutation applied to all items*).

Arg. properties

- Functional dependency: `NODES.succ` determined by `NODES.index` and `NODES.pred`.
- Functional dependency: `NODES.pred` determined by `NODES.index` and `NODES.succ`.

Usage This constraint is used in order to make the link between the successor and the predecessor variables. This is sometimes required by specific heuristics that use both predecessor and successor variables. In some problems, the successor and predecessor variables are respectively interpreted as *column* an *row* variables (i.e., we have a bijection between the successor variables and their values). This is the case, for example, in the n-queens problem (i.e., place n queens on an n by n chessboard in such a way that no two queens are on the same row, the same column or the same diagonal) when we use the following model: to each column of the chessboard we associate a variable that gives the row where the corresponding queen is located. Symmetrically, to each row of the chessboard we create a variable that indicates the column where the associated queen is placed. Having these two sets of variables, we can now write a heuristic that selects the column or the row for which we have the fewest number of alternatives for placing a queen.

Remark In the original INVERSE constraint of **CHIP** the `index` attribute was not explicitly present. It was implicitly defined as the position of a variable in a list, the first position being 1. This is also the case for **SICStus Prolog**, **JaCoP** and **Gecode** where the variables are respectively indexed from 1, 0 and 0. Within **SICStus Prolog** and **JaCoP** (`http://www.jacop.eu/`), the INVERSE constraint is called ASSIGNMENT. Within **Gecode**, it is called CHANNEL (`http://www.gecode.org/`).

Algorithm An arc-consistency filtering algorithm for the INVERSE constraint is described in [138, 139]. The algorithm is based on the following ideas:

- We first normalize the domains of the variables by removing value i from the j^{th} predecessor variable if value j does not belong to the i^{th} successor variable, and by removing value j from the i^{th} successor variable if value i does not belong to the j^{th} predecessor variable.
- Second, one can map solutions to the INVERSE constraint to perfect matchings in a so-called variable bipartite graph derived from the domain of the variables of the constraint in the following way: to each successor variable corresponds a vertex; similarly to each predecessor variable corresponds a vertex; there is and edge between the i^{th} successor variable and the j^{th} predecessor variable if and only if value i belongs to the domain of the j^{th} predecessor variable and value j belongs to the domain of the i^{th} successor variable.
- Third, Dulmage-Mendelsohn decomposition [157] is used to characterise all edges that do not belong to any perfect matching, and therefore prune the corresponding variables.

Systems INVERSECHANNELING in **Choco**, CHANNEL in **Gecode**, INVERSE in **MiniZinc**, ASSIGNMENT in **SICStus**.

Arc input(s)	NODES
Arc generator	*CLIQUE*↦collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	• nodes1.succ = nodes2.index • nodes2.pred = nodes1.index
Graph property(ies)	**NARC**= |NODES|

Graph model In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices. This is why the INVERSE constraint considers objects that have three attributes:

- One fixed attribute index that is the identifier of the vertex,
- One variable attribute succ that is the successor of the vertex,
- One variable attribute pred that is the predecessor of the vertex.

Parts (A) and (B) of Figure 5.472 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

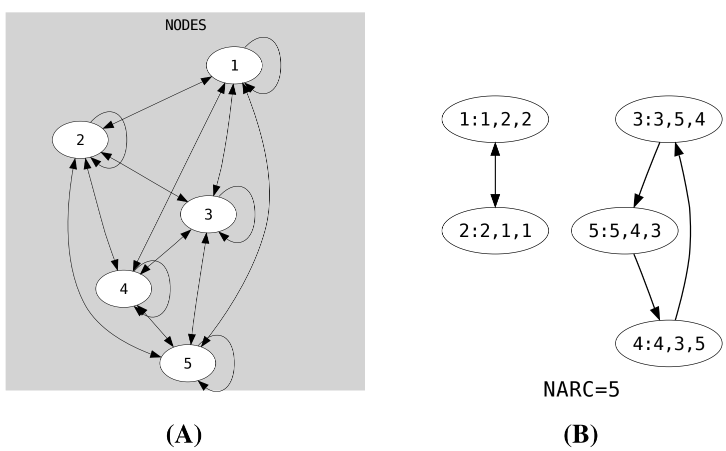

Figure 5.472: Initial and final graph of the INVERSE constraint

Signature Since all the index attributes of the NODES collection are distinct and because of the first condition nodes1.succ = nodes2.index of the arc constraint all the vertices of the final graph have at most one predecessor.

Since all the index attributes of the NODES collection are distinct and because of the second condition nodes2.pred = nodes1.index of the arc constraint all the vertices of the final graph have at most one successor.

From the two previous remarks it follows that the final graph is made up from disjoint paths and disjoint circuits. Therefore the maximum number of arcs of the final graph is equal to its maximum number of vertices NODES. So we can rewrite the graph property $\mathbf{NARC} = |\mathtt{NODES}|$ to $\mathbf{NARC} \geq |\mathtt{NODES}|$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

Automaton Figure 5.473 depicts the automaton associated with the INVERSE constraint. To each item of the collection NODES corresponds a signature variable S_i that is equal to 1.

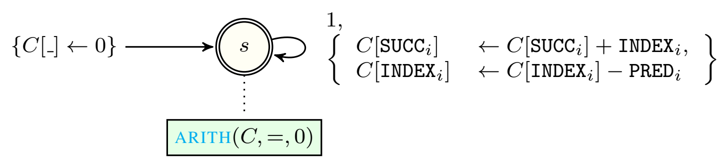

Figure 5.473: Automaton of the INVERSE constraint

5.202 INVERSE_EXCEPT_LOOP

DESCRIPTION LINKS

Origin Derived from INVERSE

Constraint INVERSE_EXCEPT_LOOP(NODES)

Argument NODES : collection(index−int, succ−dvar, pred−dvar)

Restrictions
required(NODES, [index, succ, pred])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
NODES.succ ≥ 1
NODES.succ $\leq$ |NODES|
NODES.pred ≥ 1
NODES.pred $\leq$ |NODES|

Purpose

Enforce the following conditions:

1. $\texttt{NODES}[i].\texttt{succ} = j \wedge i \neq j \Leftrightarrow \texttt{NODES}[j].\texttt{pred} = i \wedge i \neq j$,
2. $\texttt{NODES}[i].\texttt{succ} = i \Leftrightarrow \forall j \in [1, n] : \texttt{NODES}[j].\texttt{pred} \neq i$,
3. $\texttt{NODES}[i].\texttt{pred} = i \Leftrightarrow \forall j \in [1, n] : \texttt{NODES}[j].\texttt{succ} \neq i$.

Example

$$\left(\left\langle\begin{array}{lll} \texttt{index}-1 & \texttt{succ}-3 & \texttt{pred}-1, \\ \texttt{index}-2 & \texttt{succ}-4 & \texttt{pred}-2, \\ \texttt{index}-3 & \texttt{succ}-3 & \texttt{pred}-1, \\ \texttt{index}-4 & \texttt{succ}-5 & \texttt{pred}-2, \\ \texttt{index}-5 & \texttt{succ}-5 & \texttt{pred}-4 \end{array}\right\rangle\right)$$

Figure 5.474 illustrates the constraint of the **Example** slot. The INVERSE_EXCEPT_LOOP constraint holds since:

1.
   - $\texttt{NODES}[1].\texttt{succ} = 3 \wedge 1 \neq 3 \Leftrightarrow \texttt{NODES}[3].\texttt{pred} = 1 \wedge 3 \neq 1$,
   - $\texttt{NODES}[2].\texttt{succ} = 4 \wedge 2 \neq 4 \Leftrightarrow \texttt{NODES}[4].\texttt{pred} = 2 \wedge 4 \neq 2$,
   - $\texttt{NODES}[4].\texttt{succ} = 5 \wedge 4 \neq 5 \Leftrightarrow \texttt{NODES}[5].\texttt{pred} = 4 \wedge 5 \neq 4$.
2.
   - $\texttt{NODES}[3].\texttt{succ} = 3 \Leftrightarrow \forall j \in [1, 5] : \texttt{NODES}[j].\texttt{pred} \neq 3$,
   - $\texttt{NODES}[5].\texttt{succ} = 5 \Leftrightarrow \forall j \in [1, 5] : \texttt{NODES}[j].\texttt{pred} \neq 5$.
3.
   - $\texttt{NODES}[1].\texttt{pred} = 1 \Leftrightarrow \forall j \in [1, 5] : \texttt{NODES}[j].\texttt{succ} \neq 1$,
   - $\texttt{NODES}[2].\texttt{pred} = 2 \Leftrightarrow \forall j \in [1, 5] : \texttt{NODES}[j].\texttt{succ} \neq 2$.

Typical $|\texttt{NODES}| > 1$

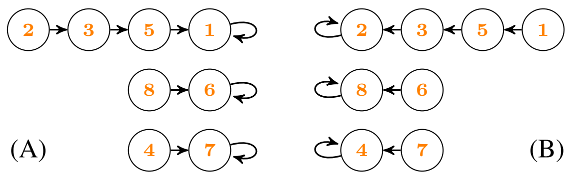

Figure 5.474: (A) Successor and (B) predecessor views corresponding to the constraint of the **Example** slot

Arg. properties

- Functional dependency: NODES.succ determined by NODES.index and NODES.pred.
- Functional dependency: NODES.pred determined by NODES.index and NODES.succ.

Usage

The INVERSE_EXCEPT_LOOP constraint can be used in the reformulation of the PATH(NPATH, $\langle 1\ s_1, \ldots, n\ s_n \rangle$) constraint. This reformulation is based on the use of two TREE constraints as well as on the use of one INVERSE_EXCEPT_LOOP channeling constraint for connecting the two TREE constraints:

- TREE(NPATH, $\langle 1\ s_1, \ldots, n\ s_n \rangle$),
- INVERSE_EXCEPT_LOOP($\langle 1\ s_1\ p_1, \ldots, n\ s_n\ p_n \rangle$),
- TREE(NPATH, $\langle 1\ p_1, \ldots, n\ p_n \rangle$).

In the context of one single path this reformulation was first mentioned in the PhD thesis of J.-G. Fages [166].

5.203 INVERSE_OFFSET

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Gecode

Constraint INVERSE_OFFSET(SOFFSET, POFFSET, NODES)

Synonym CHANNEL.

Arguments

SOFFSET : int
POFFSET : int
NODES : collection(index−int, succ−dvar, pred−dvar)

Restrictions

required(NODES, [index, succ, pred])
$\text{NODES.index} \geq 1$
$\text{NODES.index} \leq |\text{NODES}|$
distinct(NODES, index)
$\text{NODES.succ} \geq 1 + \text{SOFFSET}$
$\text{NODES.succ} \leq |\text{NODES}| + \text{SOFFSET}$
$\text{NODES.pred} \geq 1 + \text{POFFSET}$
$\text{NODES.pred} \leq |\text{NODES}| + \text{POFFSET}$

Purpose

Enforce each vertex of a digraph to have exactly one predecessor and one successor. In addition the following two statements are equivalent:

1. The successor of the i^{th} node minus **SOFFSET** is equal to j.
2. The predecessor of the j^{th} node minus **POFFSET** is equal to i.

I.e., $\text{NODES}[i].\text{succ} - \textbf{SOFFSET} = j \Leftrightarrow \text{NODES}[j].\text{pred} - \textbf{POFFSET} = i$.

Example

$$\left(\begin{array}{l} -1, 0, \left\langle \begin{array}{lll} \text{index}-1 & \text{succ}-4 & \text{pred}-3, \\ \text{index}-2 & \text{succ}-2 & \text{pred}-5, \\ \text{index}-3 & \text{succ}-0 & \text{pred}-2, \\ \text{index}-4 & \text{succ}-6 & \text{pred}-8, \\ \text{index}-5 & \text{succ}-1 & \text{pred}-1, \\ \text{index}-6 & \text{succ}-7 & \text{pred}-7, \\ \text{index}-7 & \text{succ}-5 & \text{pred}-4, \\ \text{index}-8 & \text{succ}-3 & \text{pred}-6 \end{array} \right\rangle \end{array}\right)$$

The INVERSE_OFFSET constraint holds since:

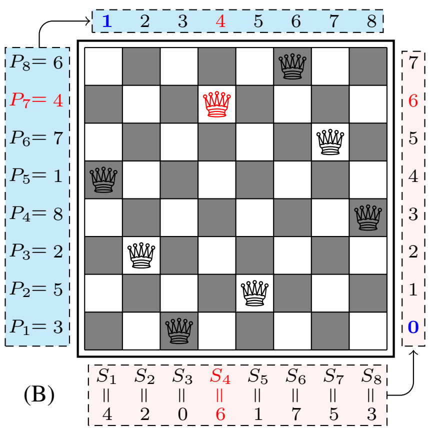
- $\text{NODES}[1].\text{succ} - (-1) = 5 \Leftrightarrow \text{NODES}[5].\text{pred} - 0 = 1$,
- $\text{NODES}[2].\text{succ} - (-1) = 3 \Leftrightarrow \text{NODES}[3].\text{pred} - 0 = 2$,
- $\text{NODES}[3].\text{succ} - (-1) = 1 \Leftrightarrow \text{NODES}[1].\text{pred} - 0 = 3$,
- $\text{NODES}[4].\text{succ} - (-1) = 7 \Leftrightarrow \text{NODES}[7].\text{pred} - 0 = 4$,
- $\text{NODES}[5].\text{succ} - (-1) = 2 \Leftrightarrow \text{NODES}[2].\text{pred} - 0 = 5$.

- $\texttt{NODES}[6].\texttt{succ} - (-1) = 8 \Leftrightarrow \texttt{NODES}[8].\texttt{pred} - 0 = 6$.
- $\texttt{NODES}[7].\texttt{succ} - (-1) = 6 \Leftrightarrow \texttt{NODES}[6].\texttt{pred} - 0 = 7$.
- $\texttt{NODES}[8].\texttt{succ} - (-1) = 4 \Leftrightarrow \texttt{NODES}[4].\texttt{pred} - 0 = 8$.

Figure 5.475 shows the board that can be associated with this example.

(A) NODES

①	index − 1	succ − 4	pred − 3
②	index − 2	succ − 2	pred − 5
③	index − 3	succ − 0	pred − 2
④	index − 4	succ − 6	pred − 8
⑤	index − 5	succ − 1	pred − 1
⑥	index − 6	succ − 7	pred − 7
⑦	index − 7	succ − 5	pred − 4
⑧	index − 8	succ − 3	pred − 6



(B)

SOFFSET = 1 POFFSET = 0

$S_1 - 1 = 5 \Leftrightarrow P_5 - 0 = 1$

$S_2 - 1 = 3 \Leftrightarrow P_3 - 0 = 2$

$S_3 - 1 = 1 \Leftrightarrow P_1 - 0 = 3$

$S_4 - 1 = 7 \Leftrightarrow P_7 - 0 = 4$

$S_5 - 1 = 2 \Leftrightarrow P_2 - 0 = 5$

$S_6 - 1 = 8 \Leftrightarrow P_8 - 0 = 6$

$S_7 - 1 = 6 \Leftrightarrow P_6 - 0 = 7$

$S_8 - 1 = 4 \Leftrightarrow P_4 - 0 = 8$

(C)

Figure 5.475: **Example** slot where we highlight the fourth item in red showing the relation between S_4 and P_7, where S_i and P_i (with $1 \leq i \leq 8$) respectively stands for the successor and predecessor attributes of the i^{th} item of the NODES collection (A) Collection of nodes passed to the INVERSE_OFFSET constraint, (B) Corresponding board, (C) Conditions linking the successor and the predecessor attributes via the offsets SOFFSET = 1 and POFFSET = 0.

Typical

SOFFSET ≥ -1
SOFFSET ≤ 1
POFFSET ≥ -1
POFFSET ≤ 1
$|\texttt{NODES}| > 1$

Symmetry

Items of NODES are permutable.

Arg. properties

- Functional dependency: NODES.succ determined by SOFFSET, POFFSET, NODES.index and NODES.pred.
- Functional dependency: NODES.pred determined by SOFFSET, POFFSET, NODES.index and NODES.succ.

Remark

The INVERSE_OFFSET constraint is called CHANNEL in **Gecode** (http://www.gecode.org/). Having two offsets was motivated by the fact that it is possible to declare arrays at any position in the **MiniZinc** modelling language.

Systems

INVERSECHANNELING in **Choco**, CHANNEL in **Gecode**.

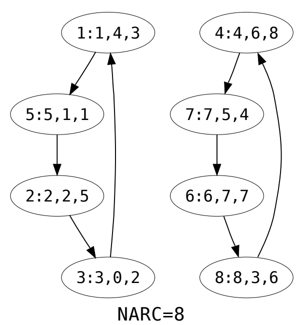
(A)



(B)

Figure 5.476: Initial and final graph of the INVERSE_OFFSET constraint

5.204 INVERSE_SET

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from INVERSE.

Constraint INVERSE_SET(X, Y)

Arguments

$$\begin{array}{lll} \texttt{X} & : & \texttt{collection}(\texttt{index}-\texttt{int}, \texttt{set}-\texttt{svar}) \\ \texttt{Y} & : & \texttt{collection}(\texttt{index}-\texttt{int}, \texttt{set}-\texttt{svar}) \end{array}$$

Restrictions

$\texttt{required}(\texttt{X}, [\texttt{index}, \texttt{set}])$
$\texttt{required}(\texttt{Y}, [\texttt{index}, \texttt{set}])$
$\texttt{increasing\_seq}(\texttt{X}, \texttt{index})$
$\texttt{increasing\_seq}(\texttt{Y}, \texttt{index})$
$\texttt{X.index} \geq 1$
$\texttt{X.index} \leq |\texttt{X}|$
$\texttt{Y.index} \geq 1$
$\texttt{Y.index} \leq |\texttt{Y}|$
$\texttt{X.set} \geq 1$
$\texttt{X.set} \leq |\texttt{Y}|$
$\texttt{Y.set} \geq 1$
$\texttt{Y.set} \leq |\texttt{X}|$

Purpose

The following two statements are equivalent:

1. Value j belongs to the set variable of the i^{th} item of the X collection.
2. Value i belongs to the set variable of the j^{th} item of the Y collection.

I.e., $j \in \texttt{X}[i] \Leftrightarrow i \in \texttt{Y}[j]$.

Example

$$\left(\begin{array}{l} \left\langle\begin{array}{ll} \texttt{index}-1 & \texttt{set}-\{2,4\}, \\ \texttt{index}-2 & \texttt{set}-\{4\}, \\ \texttt{index}-3 & \texttt{set}-\{1\}, \\ \texttt{index}-4 & \texttt{set}-\{4\} \end{array}\right\rangle, \\ \left\langle\begin{array}{ll} \texttt{index}-1 & \texttt{set}-\{3\}, \\ \texttt{index}-2 & \texttt{set}-\{1\}, \\ \texttt{index}-3 & \texttt{set}-\emptyset, \\ \texttt{index}-4 & \texttt{set}-\{1,2,4\}, \\ \texttt{index}-5 & \texttt{set}-\emptyset \end{array}\right\rangle \end{array}\right)$$

The INVERSE_SET constraint holds since:

$$\left\{\begin{array}{l} 2 \in \texttt{X}[1].\texttt{set} \Leftrightarrow 1 \in \texttt{Y}[2].\texttt{set}, \quad 4 \in \texttt{X}[1].\texttt{set} \Leftrightarrow 1 \in \texttt{Y}[4].\texttt{set}, \\ 4 \in \texttt{X}[2].\texttt{set} \Leftrightarrow 2 \in \texttt{Y}[4].\texttt{set}, \\ 1 \in \texttt{X}[3].\texttt{set} \Leftrightarrow 3 \in \texttt{Y}[1].\texttt{set}, \\ 4 \in \texttt{X}[4].\texttt{set} \Leftrightarrow 4 \in \texttt{Y}[4].\texttt{set}. \end{array}\right.$$

Typical

$|\mathtt{X}| > 1$
$|\mathtt{Y}| > 1$

Symmetries

- Arguments are permutable w.r.t. permutation $(\mathtt{X}, \mathtt{Y})$.
- Items of X are permutable.
- Items of Y are permutable.

Usage

The INVERSE_SET constraint can be used, for example, to model problems where one has to place items on a rectangular board in such a way that a column or a row can have more than one item. We have one set variable for each row of the board; Its values are the column indexes corresponding to the positions where an item is placed. Similarly we have also one set variable for each column of the board; Its values are the row indexes corresponding to the positions where an item is placed. The INVERSE_SET constraint maintains the link between the rows and the columns variables. Figure 5.477 shows the board that can be associated with the example of the **Example** slot.

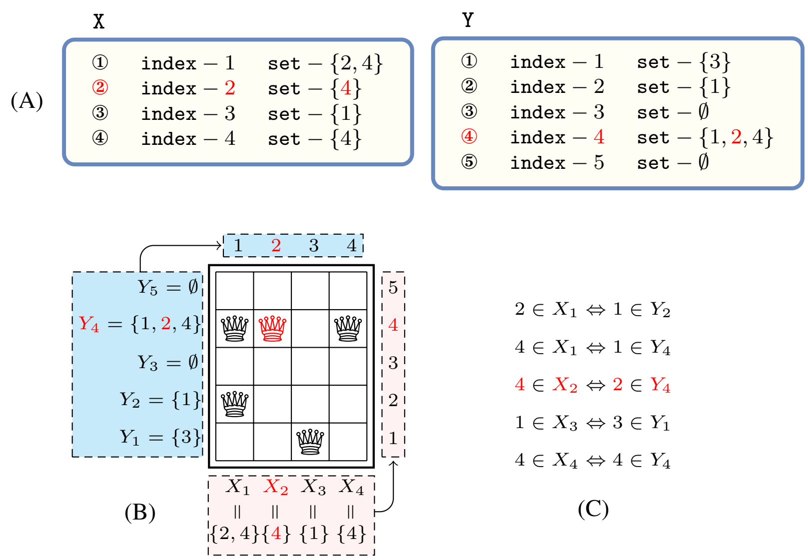


Figure 5.477: Illustration of the **Example** slot where we highlight in red the second item of the X collection and the fourth item of the Y collection showing the relation between X_2 and Y_4, where X_i (with $1 \leq i \leq 4$) and Y_j (with $1 \leq j \leq 5$) respectively stands for the set attribute of the i^{th} item of the X collection and of the j^{th} item of the Y collection (A) Collections X and Y passed to the INVERSE_SET constraint, (B) Corresponding board, (C) Conditions linking the items of X and the items of Y.

5.205 INVERSE_WITHIN_RANGE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from INVERSE.

Constraint INVERSE_WITHIN_RANGE(X, Y)

Synonyms INVERSE_IN_RANGE, INVERSE_RANGE.

Arguments

X : collection(var−dvar)
Y : collection(var−dvar)

Restrictions

required(X, var)
required(Y, var)

Purpose

If the i^{th} variable of the collection X is assigned to j and if j is greater than or equal to 1 and less than or equal to the number of items of the collection Y then the j^{th} variable of the collection Y is assigned to i.
Conversely, if the j^{th} variable of the collection Y is assigned to i and if i is greater than or equal to 1 and less than or equal to the number of items of the collection X then the i^{th} variable of the collection X is assigned to j.

Example

$(\langle 9, 4, 2\rangle, \langle 9, 3, 9, 2\rangle)$

Since the second item of X is assigned to 4, the fourth item of Y is assigned to 2. Similarly, since the third item of X is assigned to 2, the second item of Y is assigned to 3. Figure 5.479 illustrates the correspondence between X and Y.

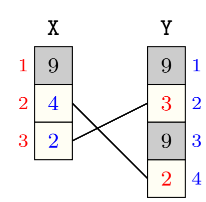

Figure 5.479: Correspondence between the items of $X = \langle 9, 4, 2\rangle$ and the items of $Y = \langle 9, 3, 9, 2\rangle$: on the X side values between 1 and $|Y| = 4$ are shown in blue, on the Y side values between 1 and $|X| = 3$ are shown in red.

Typical

$|X| > 1$
range(X.var) > 1
$|Y| > 1$
range(Y.var) > 1

Symmetry Arguments are permutable w.r.t. permutation (X, Y).

Usage Consider an integer value m and a sequence of n variables S from which you have to select a subsequence S' such that:

- All variables of S' have to be assigned to distinct values from $[1, m]$,
- All variables not in S' have to be assigned a value, not necessarily distinct, outside $[1, m]$.

As for the INVERSE constraint we may want to create explicitly a *value variable* for each value in [1,m] in order to state some specific constraints on the *value variables* or to use a heuristic involving the original variables of S as well as the *value variables*. The purpose of the INVERSE_WITHIN_RANGE constraint is to link the variables of S with the *value variables*.

See also **common keyword:** INVERSE_SET *(channelling constraint)*.

specialisation: INVERSE *(the 2 collections have not necessarly the same number of items)*.

Keywords **constraint arguments:** constraint between two collections of variables.

constraint type: graph constraint.

final graph structure: bipartite, no loop, symmetric.

heuristics: heuristics.

modelling: channelling constraint, dual model.

5.206 ITH_POS_DIFFERENT_FROM_0

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin N. Beldiceanu

Constraint ITH_POS_DIFFERENT_FROM_0(ITH, POS, VARIABLES)

Arguments

ITH	:	int
POS	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

ITH ≥ 1
ITH $\leq$ |VARIABLES|
POS $\geq$ ITH
POS $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose POS is the position of the ITHth non-zero item of the sequence of variables VARIABLES.

Example $(2, 4, \langle 3, 0, 0, 8, 6\rangle)$

The ITH_POS_DIFFERENT_FROM_0 constraint holds since 4 corresponds to the position of the 2^{th} non-zero item of the sequence 3 0 0 8 6.

Typical

|VARIABLES| > 1
range(VARIABLES.var) > 1
ATLEAST(1, VARIABLES, 0)

Typical model ATLEAST(2, VARIABLES, 0)

Symmetry An occurrence of a value of VARIABLES.var that is different from 0 can be replaced by any other value that is also different from 0.

Arg. properties Suffix-extensible wrt. VARIABLES.

Keywords

characteristic of a constraint: joker value, automaton, automaton with counters.

constraint network structure: alpha-acyclic constraint network(3).

constraint type: data constraint.

modelling: table.

Automaton Figure 5.480 depicts the automaton associated with the ITH_POS_DIFFERENT_FROM_0 constraint. To each variable $\mathtt{VAR}_i$ of the collection VARIABLES corresponds a 0-1 signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$ and S_i: $\mathtt{VAR}_i = 0 \Leftrightarrow S_i$.

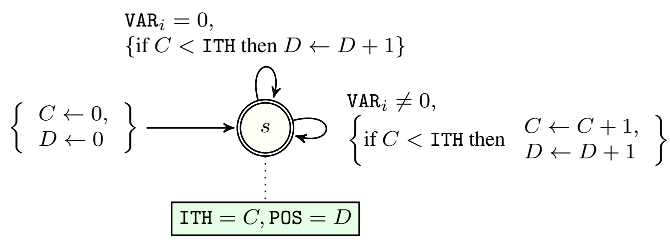

Figure 5.480: Automaton of the ITH_POS_DIFFERENT_FROM_0 constraint

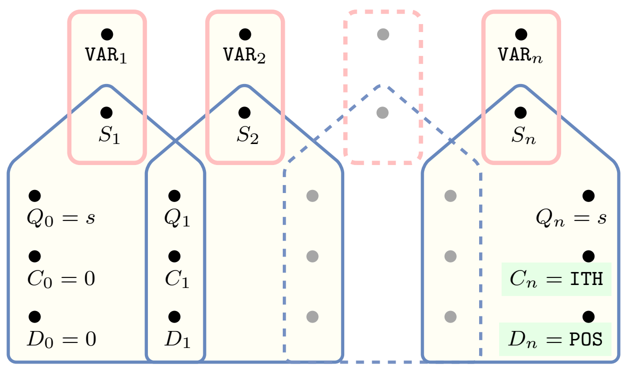

Figure 5.481: Hypergraph of the reformulation corresponding to the automaton of the ITH_POS_DIFFERENT_FROM_0 constraint

5.207 K_ALLDIFFERENT

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [160]

Constraint K_ALLDIFFERENT(VARS)

Synonyms K_ALLDIFF, K_ALLDISTINCT, SOME_DIFFERENT.

Type X : collection(x−dvar)

Argument VARS : collection(vars − X)

Restrictions
$|\mathtt{X}| \geq 1$
required(X, x)
required(VARS, vars)
$|\mathtt{VARS}| \geq 1$

Purpose For each collection of variables depicted by an item of VARS, enforce their corresponding variables to take distinct values. Usually some variables occur in several collections.

Example $(\langle \mathtt{vars} - \langle 5, 6, 0, 9, 3\rangle, \mathtt{vars} - \langle 5, 6, 1, 2\rangle\rangle)$

The K_ALLDIFFERENT constraint holds since all the values 5, 6, 0, 9 and 3 are distinct and since all the values 5, 6, 1 and 2 are distinct as well.

Typical
$|\mathtt{X}| > 1$
$|\mathtt{VARS}| > 1$

Symmetries
- Items of VARS are permutable.
- Items of VARS.vars are permutable.
- All occurrences of two distinct values of VARS.vars.x can be swapped; all occurrences of a value of VARS.vars.x can be renamed to any unused value.

Arg. properties Contractible wrt. VARS.

Usage Systems of ALLDIFFERENT constraints sharing variables occurs frequently in practice. We give 4 typical problems that can be modelled by a combination of ALLDIFFERENT constraints as well as one problem where a system of ALLDIFFERENT constraints provides a necessary condition.

- The *graph colouring* problem is to colour with a restricted number of colours the vertices of a given undirected graph in such a way that adjacent vertices are coloured with distinct colours. The problem can be modelled by a system of ALLDIFFERENT constraints. All the next problems can been seen as graph colouring problems where the graphs have some specific structure.

- A *Latin square of order* n is an $n \times n$ array in which n distinct numbers in $[1, n]$ are arranged so that each number occurs once in each row and column. The problem is to complete a partially filled Latin square. Part (A) of Figure 5.482 gives a partially filled Latin square, while part (B) provides a possible completion.

- A *task assignment* problem consists to assign a given set of non-preemptive tasks, which are fixed in time (i.e., the origin, duration and end of each task are fixed), to a set of resources so that, tasks that are assigned to the same resource do not overlap in time. Each task can be assigned to a predefined set of resources. Problems like *aircraft stand allocation* [149], [394] or *air traffic flow management* [21] correspond to an example of a real-life task assignment problem. *Assignment of service professionals* [14] is yet another industrial example where professionals have to be assigned positions in such a way that positions assigned to a given professional do not overlap in time.

  Part (A) of Figure 5.484 gives an example of task assignment problem. For each task we indicate the set of resources where it can potentially be assigned (i.e., the domain of its assignment variable). For instance, task t_1 can be assigned to resources 1 or 2. Part (B) of Figure 5.484 gives the corresponding interval graph: We have one vertex for each task and an edge between two tasks that overlap in time. We have a system of ALLDIFFERENT constraints corresponding to the maximum cliques of the interval graph (i.e., $\{t_1, t_5, t_8\}$, $\{t_2, t_5, t_8\}$, $\{t_2, t_6\}$, $\{t_3, t_6, t_9\}$, $\{t_3, t_7, t_9\}$, $\{t_4, t_7, t_9\}$). Finally, part (C) of Figure 5.484 provides a possible solution to the task assignment problem where tasks t_1, t_2, t_9 are assigned to resource 1, tasks t_3, t_4, t_8 are assigned to resource 2, and tasks t_5, t_6, t_7 are assigned to resource 3.

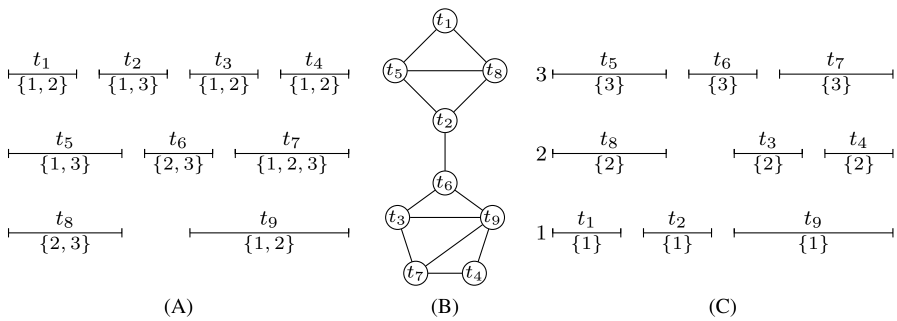

Figure 5.484: (A) Tasks $t_1, t_2, \ldots, t_9$ with their potential assignments 1, 2 or 3 (B) Interval graph where to each task of corresponds a vertex, and to each pair of overlapping tasks corresponds an edge (C) A valid assignment where tasks assigned to a same machine do not overlap

- The *tree partitioning with precedences* problem is to compute a vertex-partitioning of a given digraph $\mathcal{G}$ in disjoint trees (i.e., a forest), so that a given set of precedences holds. The problem can be modelled with a TREE_PRECEDENCE(`NTREE`, `VERTICES`) constraint, where `NTREE` is a domain variable specifying the numbers of trees in the forest and `VERTICES` is a collection of the digraph's n vertices. Each item $v \in$ `VERTICES` has the following attributes, which complete the description of the digraph:

  - `index` is an integer in $[1, n]$ that can be interpreted as the *label* of v.
  - `father` is a domain variable whose domain consists of elements (vertex label) of $[1, n]$. It can be interpreted as the *unique successor* of v.
  - `preds` is a possibly empty set of integers, its elements (vertex label) being in $[1, n]$. It can be interpreted as the *mandatory ancestors* of v.

  We model the TREE_PRECEDENCE constraint by the digraph $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ in which the vertices represent the elements of `VERTICES` and the arcs represent the successors relations between them. Formally, $\mathcal{G}$ is defined as follows:

  - To the i^{th} vertex ($1 \leq i \leq n$), `VERTICES`$[i]$, of the `VERTICES` collection corresponds a vertex of $\mathcal{V}$ denoted by v_i.
  - For every pair of vertices (`VERTICES`$[i]$,`VERTICES`$[j]$), where i and j are not necessarily distinct, there is an arc from v_i to v_j in $\mathcal{E}$.

  The TREE_PRECEDENCE constraint specifies that its associated digraph $\mathcal{G}$ should be a forest that fulfils the precedence constraints. Formally a ground instance of a TREE_PRECEDENCE(NTREE, VERTICES) constraint is satisfied if and only if the following conditions hold:

1. $\forall i \in [1, n]$: VERTICES$[i]$.index $= i$,
2. Its associated digraph $\mathcal{G}$ consists of NTREE connected components,
3. Each connected component of $\mathcal{G}$ does not contain any circuit involving more than one vertex,
4. For every vertex VERTICES$[i]$ such that $j \in$ VERTICES$[i]$.preds there must be an elementary path in $\mathcal{G}$ from VERTICES$[j]$ to VERTICES$[i]$.

We can build the following system of ALLDIFFERENT constraints that corresponds to a necessary condition for the TREE_PRECEDENCE constraint: To each vertex v of $\mathcal{G}$, which both has no predecessors and cannot be the root of a tree, we generate an ALLDIFFERENT constraint involving the father variables of those descendants of v in $\mathcal{G}$ that cannot be the root of a tree.

For the set of precedences depicted by part (A) of Figure 5.485[13], where we assume that VERTICES$[12]$ is the only vertex that can be a root and where F_i denotes the father variable associated with VERTICES$[i]$, we get the following system of ALLDIFFERENT constraints:

- ALLDIFFERENT$(\langle F_1, F_3, F_5, F_6, F_7, F_{10}, F_{11}\rangle)$,
- ALLDIFFERENT$(\langle F_2, F_4, F_7, F_8, F_9, F_{10}, F_{11}\rangle)$.

The variables of these two ALLDIFFERENT constraints respectively correspond to the descendants of the two source vertices (i.e., F_1 and F_2) of the precedence graph depicted by parts (B) and (C) of Figure 5.485. On part (B) and (C) of Figure 5.485 the descendants of F_1 and F_2 are respectively depicted in red and blue. Their intersections, $\{F_7, F_{10}, F_{11}, F_{12}\}$, from which we remove F_{12} belong to the two ALLDIFFERENT constraints. In fact, F_{12} is not mentioned in the two ALLDIFFERENT constraints since its corresponding vertex is the root of a tree. Part (D) of Figure 5.485 gives a possible tree satisfying all the precedences constraints expressed by part (A). It corresponds to the following ground solution:

TREE_PRECEDENCE($\langle$ index $-$ 1 father $-$ 3 preds $-\{\}$,
index $-$ 2 father $-$ 4 preds $-\{\}$,
index $-$ 3 father $-$ 5 preds $-\{1\}$,
index $-$ 4 father $-$ 8 preds $-\{2\}$,
index $-$ 5 father $-$ 6 preds $-\{1\}$,
index $-$ 6 father $-$ 7 preds $-\{3\}$,
index $-$ 7 father $-$ 10 preds $-\{3,4\}$,
index $-$ 8 father $-$ 9 preds $-\{4\}$,
index $-$ 9 father $-$ 7 preds $-\{2\}$,
index $-$ 10 father $-$ 11 preds $-\{5,6,7\}$,
index $-$ 11 father $-$ 12 preds $-\{7,8,9\}$,
index $-$ 12 father $-$ 12 preds $-\{10,11\}$ $\rangle$)

Parts (E) and (F) of Figure 5.485 illustrate how the precedence constraints are satisfied by the solution depicted by part (D): each precedence, represented by a dashed arc, links two vertices that belong to a same path of the tree that is directed toward the root of the tree.

[13] The number in a vertex gives the value of the index attribute of the corresponding item.

Remark It was shown in [161] that, finding out whether a system of two ALLDIFFERENT constraints sharing some variables has a solution or not is NP-hard. This was achieved by reduction from set packing.

A slight variation in the way of describing the arguments of the K_ALLDIFFERENT constraint appears in [368] under the name of SOME_DIFFERENT: the set of disequalities is described by a set of pairs of variables, where each pair corresponds to a disequality constraint between two given variables.

Within the context of linear programming, a relaxation of the K_ALLDIFFERENT constraint is provided in [9]. The special case where $k = 2$ is discussed in [10].

Algorithm Even if there is no filtering algorithm for the K_ALLDIFFERENT constraint, one can enforce redundant constraints for the following patterns:

- Within the context of graph colouring, one can state an NVALUE constraint for every cycle of odd length of the graph to colour enforcing that the corresponding variables have to be assigned to at least three distinct values.
- Within the context of Latin squares, one can state a COLORED_MATRIX constraint enforcing that each value is used exactly once in each row and column.
- Within the context of two ALLDIFFERENT constraints ALLDIFFERENT($\langle U_1, \ldots, U_n, V_1, \ldots, V_m \rangle$) and ALLDIFFERENT($\langle U_1, \ldots, U_n, W_1, \ldots, W_m \rangle$) where the domain of all variables $U_1, \ldots, U_n$, $V_1, \ldots, V_m$, $W_1, \ldots, W_m$ is included in the interval $[1, n + m]$, one can state a SAME_AND_GLOBAL_CARDINALITY constraint stating that the variables $V_1, \ldots, V_m$ should correspond to a permutation of the variables $W_1, \ldots, W_m$ and that the variables $V_1, \ldots, V_m$ should be assigned to distinct values.
- In the general case of two ALLDIFFERENT constraints ALLDIFFERENT($\langle U_1, \ldots, U_n, V_1, \ldots, V_m \rangle$) and ALLDIFFERENT($\langle U_1, \ldots, U_n, W_1, \ldots, W_o \rangle$), one can state an NVALUE constraint involving the variables $V_1, \ldots, V_m$ and $W_1, \ldots, W_o$ enforcing that these variables should not use more than $s - n$ distinct values, where s denotes the cardinality of the union of the domains of the variables $U_1, \ldots, U_n$, $V_1, \ldots, V_m$, $W_1, \ldots, W_o$.

Several propagation rules for the K_ALLDIFFERENT constraint are also described in [264].

Reformulation Given two ALLDIFFERENT constraints that share some variables, a reformulation preserving bound-consistency was introduced in [80]. This reformulation is based on an extension of Hall's theorem that is presented in the same paper.

Keywords

application area: air traffic management, assignment.

characteristic of a constraint: all different, disequality.

combinatorial object: permutation, Latin square.

complexity: set packing.

constraint type: system of constraints, overlapping alldifferent, value constraint, decomposition.

filtering: bound-consistency, duplicated variables.

problems: graph colouring.

puzzles: Sudoku.

For all items of VARS:

Arc input(s)	VARS.vars
Arc generator	$CLIQUE \mapsto$ collection(x1, x2)
Arc arity	2
Arc constraint(s)	x1.x = x2.x
Graph property(ies)	**MAX_NSCC** ≤ 1

Graph model For each collection of variables depicted by an item of VARS we generate a *clique* with an *equality* constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed one.

5.208 K_CUT

DESCRIPTION LINKS GRAPH

Origin E. Althaus

Constraint K_CUT(K, NODES)

Arguments

K : int
NODES : collection(index−int, succ−svar)

Restrictions

$\mathtt{K} \geq 1$
$\mathtt{K} \leq |\mathtt{NODES}|$
required(NODES, [index, succ])
$\mathtt{NODES.index} \geq 1$
$\mathtt{NODES.index} \leq |\mathtt{NODES}|$
distinct(NODES, index)
$\mathtt{NODES.succ} \geq 1$
$\mathtt{NODES.succ} \leq |\mathtt{NODES}|$

Purpose Select some arcs of a digraph in order to have at least K connected components (an isolated vertex, i.e. a vertex without any ingoing or outgoing arc, is counted as one connected component).

Example

$$\left(3, \left\langle \begin{array}{ll} \mathtt{index}-1 & \mathtt{succ}-\emptyset, \\ \mathtt{index}-2 & \mathtt{succ}-\{3,5\}, \\ \mathtt{index}-3 & \mathtt{succ}-\{5\}, \\ \mathtt{index}-4 & \mathtt{succ}-\emptyset, \\ \mathtt{index}-5 & \mathtt{succ}-\{2,3\} \end{array} \right\rangle \right)$$

The K_CUT constraint holds since the graph corresponding to the NODES collection contains 3 connected components (i.e., two connected components respectively involving vertices 1 and 4 and a third connected component containing the remaining vertices 2, 3 and 5), and since the first argument K enforces to have at least 3 connected components.

Typical $|\mathtt{NODES}| > 1$

Symmetries

- K can be decreased to any value ≥ 1.
- Items of NODES are permutable.

See also **common keyword:** LINK_SET_TO_BOOLEANS *(constraint involving set variables)*.

used in graph description: IN_SET.

Keywords **constraint arguments:** constraint involving set variables.

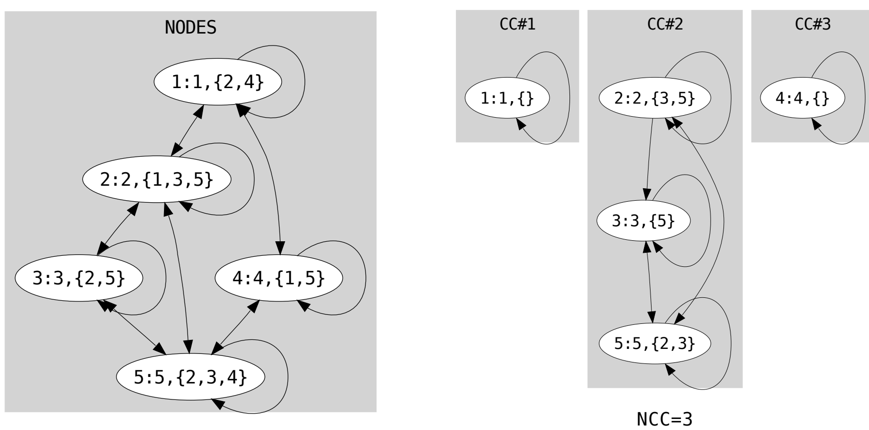
constraint type: graph constraint.

filtering: linear programming.

final graph structure: connected component.

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	$\bigvee \left(\begin{array}{l} \texttt{nodes1.index} = \texttt{nodes2.index}, \\ \texttt{IN\_SET}(\texttt{nodes2.index}, \texttt{nodes1.succ}) \end{array} \right)$
Graph property(ies)	**NCC** $\geq$ K

Graph model nodes1.index = nodes2.index holds if nodes1 and nodes2 correspond to the same vertex. It is used in order to enforce keeping all the vertices of the initial graph. This is because an isolated vertex counts always as one connected component. Within the context of the **Example** slot, part (A) of Figure 5.486 shows the initial graph from which we have chosen to start. It is derived from the set associated with each vertex. Each set describes the potential values of the succ attribute of a given vertex. Part (B) of Figure 5.486 gives the final graph associated with the example of the **Example** slot. The K_CUT constraint holds since we have at least K = 3 connected components in the final graph.



(A) **(B)**

Figure 5.486: Initial and final graph of the K_CUT set constraint

5.209 K_DISJOINT

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from DISJOINT

Constraint K_DISJOINT(SETS)

Type VARIABLES : collection(var−dvar)

Argument SETS : collection(set − VARIABLES)

Restrictions
required(VARIABLES, var)
$|\texttt{VARIABLES}| \geq 1$
required(SETS, set)
$|\texttt{SETS}| > 1$

Purpose Given |SETS| sets of domain variables, the K_DISJOINT constraint forces that no value is assigned to more than one set.

Example $(\langle \texttt{set} - \langle 1, 9, 1, 5\rangle, \texttt{set} - \langle 2, 7, 7, 0, 6, 8\rangle, \texttt{set} - \langle 4, 4, 3\rangle\rangle)$

The K_DISJOINT constraint holds since:

- The set of values $\{1, 5, 9\}$ and $\{0, 2, 6, 7, 8\}$ respectively assigned to the variables of the first and second collections have an empty intersection.
- The set of values $\{1, 5, 9\}$ and $\{3, 4\}$ respectively assigned to the variables of the first and third collections have an empty intersection.
- The set of values $\{0, 2, 6, 7, 8\}$ and $\{3, 4\}$ respectively assigned to the variables of the second and third collections have an empty intersection.

Typical $|\texttt{VARIABLES}| > 1$

Symmetries
- Items of SETS are permutable.
- Items of SETS.set are permutable.
- An occurrence of a value of VARIABLES.var can be replaced by any value of VARIABLES.var.
- All occurrences of two distinct values of SETS.set.var can be swapped; all occurrences of a value of SETS.set.var can be renamed to any unused value.

Arg. properties Contractible wrt. SETS.

See also **part of system of constraints:** DISJOINT.
used in graph description: DISJOINT.

Keywords **characteristic of a constraint:** disequality.

constraint type: system of constraints, decomposition, value constraint.

modelling: empty intersection.

Arc input(s)	SETS
Arc generator	$CLIQUE(<) \mapsto$ collection(set1, set2)
Arc arity	2
Arc constraint(s)	DISJOINT(set1.set, set2.set)
Graph property(ies)	**NARC** $= \lvert$SETS$\rvert * (\lvert$SETS$\rvert - 1)/2$

Graph model Parts (A) and (B) of Figure 5.487 respectively show the initial and final graph associated with the **Example** slot. To each vertex corresponds a collection of variables, while to each arc corresponds a DISJOINT constraint.

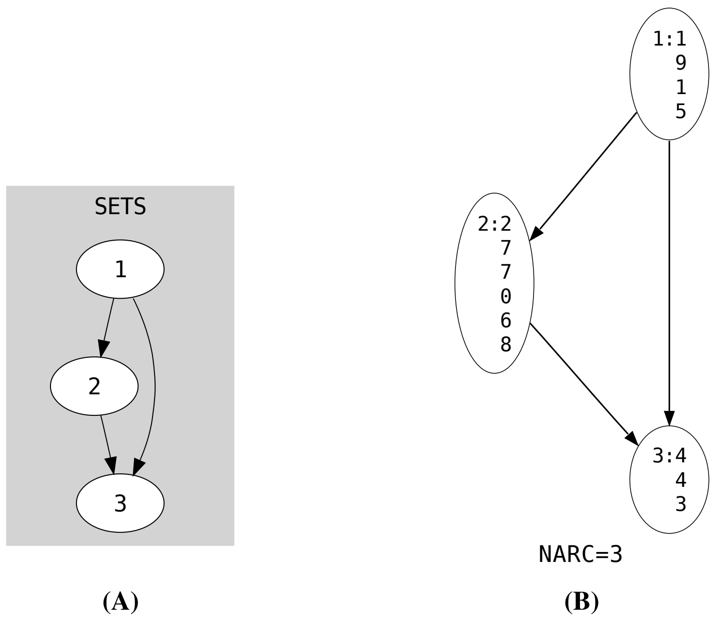


Figure 5.487: Initial and final graph of the K_DISJOINT constraint

5.210 K_SAME

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [160]

Constraint K_SAME(SETS)

Type VARIABLES : collection(var−dvar)

Argument SETS : collection(set − VARIABLES)

Restrictions
required(VARIABLES, var)
$|\text{VARIABLES}| \geq 1$
required(SETS, set)
$|\text{SETS}| > 1$
same_size(SETS, set)

Purpose Given |SETS| sets, each containing the same number of domain variables, the K_SAME constraint forces that the multisets of values assigned to each set are all identical.

Example

$$\left(\left\langle \begin{array}{l} \text{set} - \langle 1,9,1,5,2,1 \rangle, \\ \text{set} - \langle 9,1,1,1,2,5 \rangle, \\ \text{set} - \langle 5,2,1,1,9,1 \rangle \end{array} \right\rangle \right)$$

The K_SAME constraint holds since:

- The first and second collections of variables are assigned to the same multiset.
- The second and third collections of variables are also assigned to the same multiset.

Typical $|\text{VARIABLES}| > 1$

Symmetries
- Items of SETS are permutable.
- Items of SETS.set are permutable.
- All occurrences of two distinct values of SETS.set.var can be swapped; all occurrences of a value of SETS.set.var can be renamed to any unused value.

Arg. properties Contractible wrt. SETS.

Remark It was shown in [160] that, finding out whether the K_SAME constraint has a solution or not is NP-hard when we have more than one SAME constraint. This was achieved by reduction from 3-dimensional-matching in the context where we have 2 SAME constraints.

See also

common keyword: K_SAME_INTERVAL, K_SAME_MODULO, K_SAME_PARTITION *(system of constraints)*.

implies: K_USED_BY.

part of system of constraints: SAME.

used in graph description: SAME.

Keywords

characteristic of a constraint: sort based reformulation.

combinatorial object: permutation, multiset.

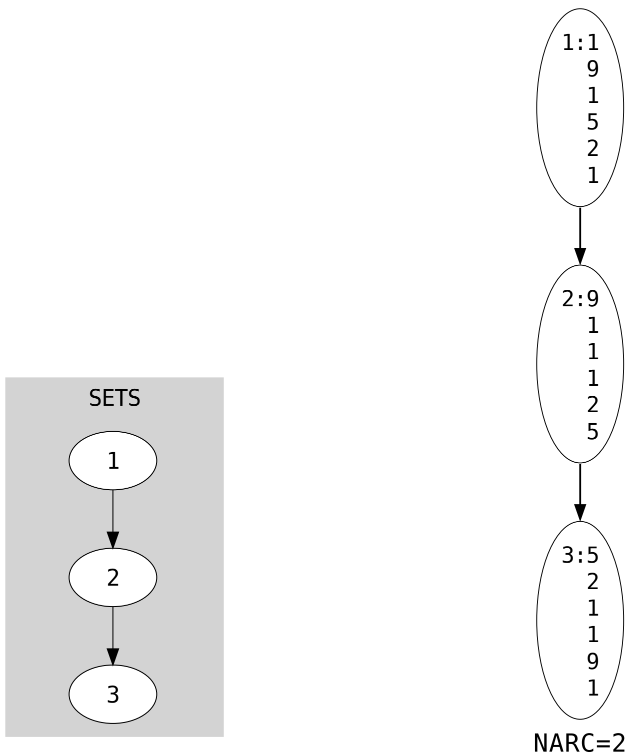
complexity: 3-dimensional-matching.

constraint type: system of constraints, decomposition.

modelling: equality between multisets.

Arc input(s)	SETS
Arc generator	$PATH \mapsto$ collection(set1, set2)
Arc arity	2
Arc constraint(s)	SAME(set1.set, set2.set)
Graph property(ies)	**NARC** $= \lvert$SETS$\rvert - 1$

Graph model Parts (A) and (B) of Figure 5.488 respectively show the initial and final graph associated with the **Example** slot. To each vertex corresponds a collection of variables, while to each arc corresponds a SAME constraint.



(A) (B)

Figure 5.488: Initial and final graph of the K_SAME constraint

5.211 K_SAME_INTERVAL

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from SAME_INTERVAL and from K_SAME.

Constraint K_SAME_INTERVAL(SETS, SIZE_INTERVAL)

Type VARIABLES : collection(var−dvar)

Arguments

SETS : collection(set − VARIABLES)
SIZE_INTERVAL : int

Restrictions

required(VARIABLES, var)
$|\texttt{VARIABLES}| \geq 1$
required(SETS, set)
$|\texttt{SETS}| > 1$
same_size(SETS, set)
$\texttt{SIZE\_INTERVAL} > 0$

Purpose Given a collection of |SETS| sets, each containing the same number of domain variables, the K_SAME_INTERVAL constraint forces a SAME_INTERVAL constraint between each pair of consecutive sets.

Example

$$\left(\left\langle\begin{array}{l}\texttt{set} - \langle 1,1,6,0,1,7\rangle,\\ \texttt{set} - \langle 8,8,0,0,1,2\rangle,\\ \texttt{set} - \langle 2,1,1,2,6,6\rangle\end{array}\right\rangle, 3\right)$$

In the example, the second argument SIZE_INTERVAL $= 3$ of the K_SAME_INTERVAL constraint defines the following family of intervals $[3\cdot k, 3\cdot k+2]$, where k is an integer. The K_SAME_INTERVAL constraint holds since:

- The first and second collections of variables are assigned 4 values in the interval $[0,2]$ as well as 2 values in the interval $[6,8]$.
- The second and third collections of variables are also assigned 4 values in the interval $[0,2]$ as well as 2 values in the interval $[6,8]$.

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{SIZE\_INTERVAL} > 1$

Symmetries

- Items of SETS are permutable.
- Items of SETS.set are permutable.
- An occurrence of a value of SETS.set.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Arg. properties Contractible wrt. SETS.

Arc arity	2
Arc constraint(s)	SAME_INTERVAL(set1.set, set2.set, SIZE_INTERVAL)
Graph property(ies)	**NARC**$= \|$SETS$\| - 1$

Graph model Parts (A) and (B) of Figure 5.489 respectively show the initial and final graph associated with the **Example** slot. To each vertex corresponds a collection of variables, while to each arc corresponds a SAME_INTERVAL constraint.

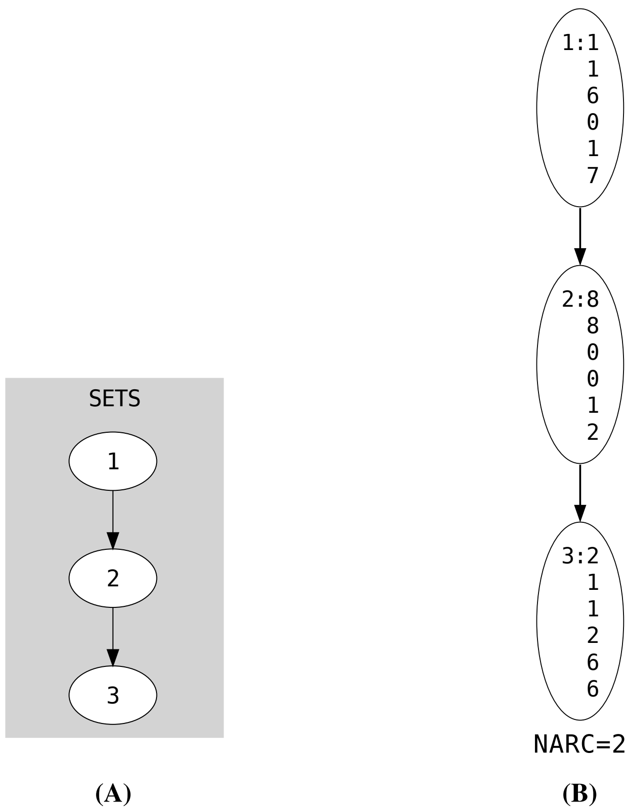

Figure 5.489: Initial and final graph of the K_SAME_INTERVAL constraint

5.212 K_SAME_MODULO

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from SAME_MODULO and from K_SAME.

Constraint K_SAME_MODULO(SETS, M)

Type VARIABLES : collection(var−dvar)

Arguments

SETS : collection(set − VARIABLES)
M : int

Restrictions

required(VARIABLES, var)
$|\text{VARIABLES}| \geq 1$
required(SETS, set)
$|\text{SETS}| > 1$
same_size(SETS, set)
$\text{M} > 0$

Purpose Given a collection of |SETS| sets, each containing the same number of domain variables, the K_SAME_MODULO constraint forces a SAME_MODULO constraint between each pair of consecutive sets.

Example

$$\left(\left\langle\begin{array}{l}\text{set} - \langle 1,9,1,5,2,1\rangle,\\ \text{set} - \langle 6,4,1,1,5,5\rangle,\\ \text{set} - \langle 1,3,4,2,8,7\rangle\end{array}\right\rangle, 3\right)$$

The K_SAME_MODULO constraint holds since:

- The first and second collections of variables are assigned 1 value in $\{0,3,\ldots,3\cdot k\}$, 3 values in $\{1,4,\ldots,1+3\cdot k\}$ and 2 values in $\{2,5,\ldots,2+3\cdot k\}$.
- The second and third collections of variables are also assigned 1 value in $\{0,3,\ldots,3\cdot k\}$, 3 values in $\{1,4,\ldots,1+3\cdot k\}$ and 2 values in $\{2,5,\ldots,2+3\cdot k\}$.

Typical

$|\text{VARIABLES}| > 1$
$\text{M} > 1$

Symmetries

- Items of SETS are permutable.
- Items of SETS.set are permutable.
- An occurrence of a value u of SETS.set.var can be replaced by any other value v such that v is congruent to u modulo M.

Arg. properties Contractible wrt. SETS.

Arc generator	$PATH \mapsto$ collection(set1, set2)
Arc arity	2
Arc constraint(s)	SAME_MODULO(set1.set, set2.set, M)
Graph property(ies)	**NARC** $= \vert$SETS$\vert - 1$

Graph model Parts (A) and (B) of Figure 5.490 respectively show the initial and final graph associated with the **Example** slot. To each vertex corresponds a collection of variables, while to each arc corresponds a SAME_MODULO constraint.

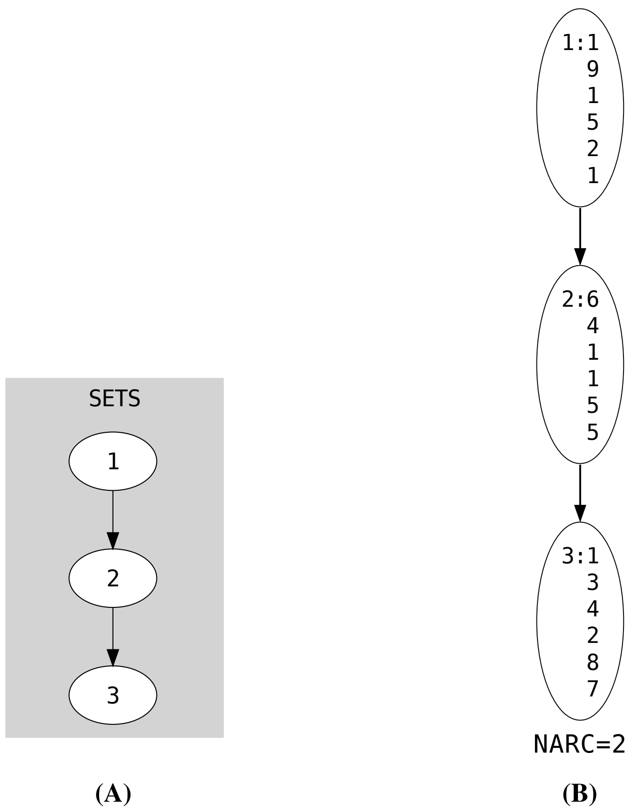

Figure 5.490: Initial and final graph of the K_SAME_MODULO constraint

5.213 K_SAME_PARTITION

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from SAME_PARTITION and from K_SAME.

Constraint K_SAME_PARTITION(SETS, PARTITIONS)

Types

VARIABLES : collection(var−dvar)
VALUES : collection(val−int)

Arguments

SETS : collection(set − VARIABLES)
PARTITIONS : collection(p − VALUES)

Restrictions

required(VARIABLES, var)
$|\texttt{VARIABLES}| \geq 1$
$|\texttt{VALUES}| \geq 1$
required(VALUES, val)
distinct(VALUES, val)
required(SETS, set)
$|\texttt{SETS}| > 1$
same_size(SETS, set)
required(PARTITIONS, p)
$|\texttt{PARTITIONS}| \geq 2$

Purpose Given a collection of |SETS| sets, each containing the same number of domain variables, the K_SAME_PARTITION constraint forces a SAME_PARTITION constraint between each pair of consecutive sets.

Example

$$\left(\begin{array}{c}\left\langle\begin{array}{l}\texttt{set}-\langle 1,2,6,3,1,2\rangle,\\ \texttt{set}-\langle 6,6,2,3,1,3\rangle,\\ \texttt{set}-\langle 2,2,2,1,1,1\rangle\end{array}\right\rangle,\\ \langle \texttt{p}-\langle 1,3\rangle,\texttt{p}-\langle 4\rangle,\texttt{p}-\langle 2,6\rangle\rangle\end{array}\right)$$

The first argument SETS of the K_SAME_PARTITION constraint corresponds to 3 collections of variables, while the second argument PARTITIONS defines the 3 sets of values $\{1,3\}$, $\{4\}$ and $\{2,6\}$. The K_SAME_PARTITION constraint holds since:

- The first and second collections of variables are assigned 3 values in the $\{1,3\}$ as well as 3 values in $\{2,6\}$.
- The second and third collections of variables are also assigned 3 values in the $\{1,3\}$ as well as 3 values in $\{2,6\}$.

Typical $|\texttt{VARIABLES}| > 1$

Symmetries

- Items of SETS are permutable.
- Items of SETS.set are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of SETS.set.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Arg. properties

Contractible wrt. SETS.

See also

common keyword: K_SAME *(system of constraints)*.

Graph model Parts (A) and (B) of Figure 5.491 respectively show the initial and final graph associated with the **Example** slot. To each vertex corresponds a collection of variables, while to each arc corresponds a SAME_PARTITION constraint.

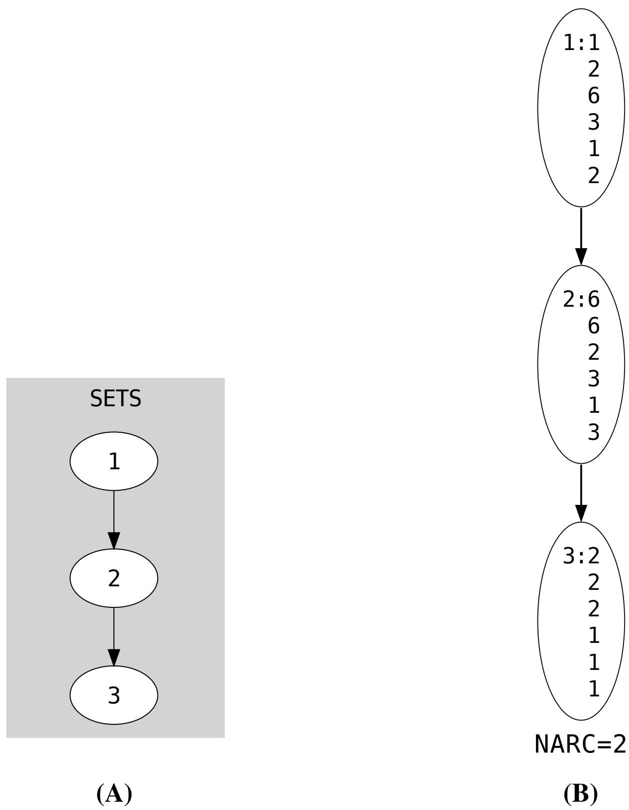

Figure 5.491: Initial and final graph of the K_SAME_PARTITION constraint

5.214 K_USED_BY

DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY

Constraint K_USED_BY(SETS)

Type VARIABLES : collection(var−dvar)

Argument SETS : collection(set − VARIABLES)

Restrictions
required(VARIABLES, var)
$|\text{VARIABLES}| \geq 1$
required(SETS, set)
$|\text{SETS}| > 1$
non_increasing_size(SETS, set)

Purpose Given |SETS| sets of domain variables, the K_USED_BY constraint forces a USED_BY constraint between each pair of consecutive sets.

Example

$$\left(\left\langle\begin{array}{l}\text{set} - \langle 1,9,1,5,2,1\rangle,\\ \text{set} - \langle 9,1,1,1,2,5\rangle,\\ \text{set} - \langle 1,1,2,5\rangle\end{array}\right\rangle\right)$$

The K_USED_BY constraint holds since:

- The multiset of values $\{\{1,1,1,2,5,9\}\}$ associated with the second collection of variables is included into the multiset $\{\{1,1,1,2,5,9\}\}$ associated with the first collection of variables.
- The multiset of values $\{\{1,1,2,5\}\}$ associated with the third collection of variables is included into the multiset $\{\{1,1,1,2,5,9\}\}$ associated with the second collection of variables.

Typical $|\text{VARIABLES}| > 1$

Symmetries
- Items of SETS are permutable.
- Items of SETS.set are permutable.
- All occurrences of two distinct values of SETS.set.var can be swapped; all occurrences of a value of SETS.set.var can be renamed to any unused value.

Arg. properties Contractible wrt. SETS.

Remark Similarly to the K_SAME constraint [160], finding out whether the K_USED_BY constraint has a solution or not is NP-hard when we have more than one USED_BY constraint.

5.215 K_USED_BY_INTERVAL

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY_INTERVAL and from K_USED_BY.

Constraint K_USED_BY_INTERVAL(SETS, SIZE_INTERVAL)

Type VARIABLES : collection(var−dvar)

Arguments

SETS : collection(set − VARIABLES)
SIZE_INTERVAL : int

Restrictions

required(VARIABLES, var)
$|\texttt{VARIABLES}| \geq 1$
required(SETS, set)
$|\texttt{SETS}| > 1$
non_increasing_size(SETS, set)
$\texttt{SIZE\_INTERVAL} > 0$

Purpose Given |SETS| sets of domain variables, the K_USED_BY_INTERVAL constraint forces a USED_BY_INTERVAL constraint between each pair of consecutive sets.

Example

$(\langle \texttt{set} - \langle 1, 1, 1, 8, 6, 2\rangle, \texttt{set} - \langle 1, 0, 7, 7\rangle, \texttt{set} - \langle 1, 2\rangle\rangle, 3)$

In the example, the second argument $\texttt{SIZE\_INTERVAL} = 3$ defines the following family of intervals $[3 \cdot k, 3 \cdot k + 2]$, where k is an integer. Consequently, the K_USED_BY_INTERVAL constraint holds since:

- The first collection of variables is assigned 4 values in the interval $[0, 2]$ as well as 2 values in the interval $[6, 8]$, while the second collection of variables is assigned no more values in the previous two intervals.
- The second collection of variables is assigned 2 values in the interval $[0, 2]$ as well as 2 values in the interval $[6, 8]$, while the third collection of variables is assigned no more values in the previous two intervals.

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{SIZE\_INTERVAL} > 0$

Symmetries

- Items of SETS are permutable.
- Items of SETS.set are permutable.
- An occurrence of a value of SETS.set.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Arg. properties Contractible wrt. SETS.

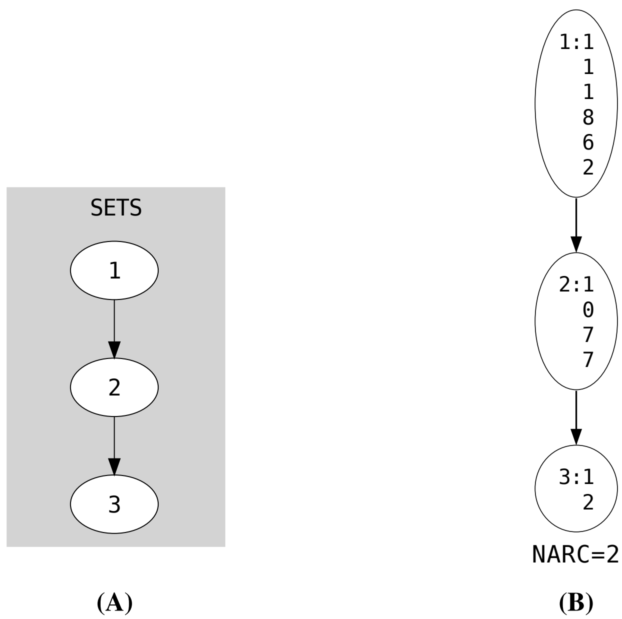

Figure 5.493: Initial and final graph of the K_USED_BY_INTERVAL constraint

5.216 K_USED_BY_MODULO

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY_MODULO and from K_USED_BY.

Constraint K_USED_BY_MODULO(SETS, M)

Type VARIABLES : collection(var−dvar)

Arguments

SETS : collection(set − VARIABLES)
M : int

Restrictions

required(VARIABLES, var)
$|$VARIABLES$| \geq 1$
required(SETS, set)
$|$SETS$| > 1$
non_increasing_size(SETS, set)
$\mathtt{M} > 0$

Purpose Given |SETS| sets of domain variables, the K_USED_BY_MODULO constraint forces a USED_BY_MODULO constraint between each pair of consecutive sets.

Example $(\langle \mathtt{set} - \langle 1, 9, 4, 5, 2, 1\rangle, \mathtt{set} - \langle 7, 1, 2, 5\rangle, \mathtt{set} - \langle 1, 1\rangle\rangle, 3)$

The K_USED_BY_MODULO constraint holds since:

- The first collection of variables is assigned 1 value in $\{0, 3, \ldots, 3 \cdot k\}$, 3 values in $\{1, 4, \ldots, 1+3\cdot k\}$ and 2 values in $\{2, 5, \ldots, 2+3\cdot k\}$, while the second collection of variables is assigned no more values in the previous three sets of values.
- The second collection of variables is assigned 2 values in $\{0, 3, \ldots, 3 \cdot k\}$ and 2 values in $\{2, 5, \ldots, 2 + 3 \cdot k\}$, while the third collection of variables is assigned no more values in the previous three sets of values.

Typical

$|$VARIABLES$| > 1$
$\mathtt{M} > 1$

Symmetries

- Items of SETS are permutable.
- Items of SETS.set are permutable.
- An occurrence of a value u of SETS.set.var can be replaced by any other value v such that v is congruent to u modulo M.

Arg. properties Contractible wrt. SETS.

Graph property(ies)	**NARC** $= \vert$SETS$\vert - 1$

Graph model Parts (A) and (B) of Figure 5.494 respectively show the initial and final graph associated with the **Example** slot. To each vertex corresponds a collection of variables, while to each arc corresponds a USED_BY_MODULO constraint.

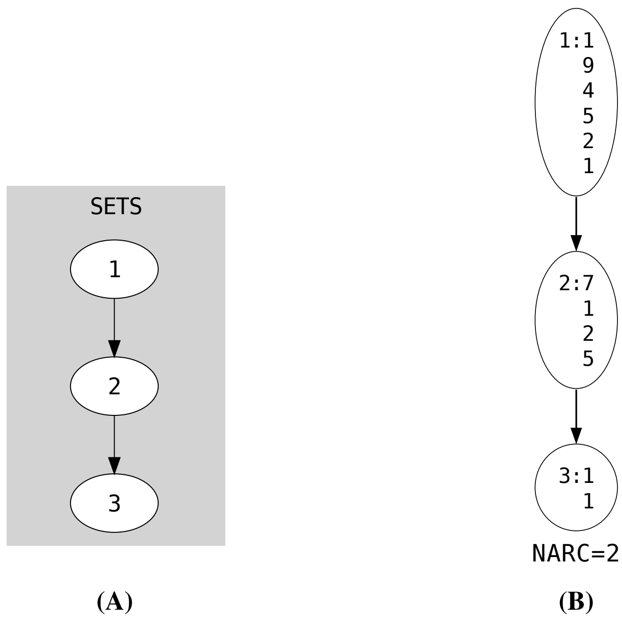

Figure 5.494: Initial and final graph of the K_USED_BY_MODULO constraint

5.217 K_USED_BY_PARTITION

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY_PARTITION and from K_USED_BY.

Constraint K_USED_BY_PARTITION(SETS, PARTITIONS)

Types

VARIABLES : collection(var−dvar)
VALUES : collection(val−int)

Arguments

SETS : collection(set − VARIABLES)
PARTITIONS : collection(p − VALUES)

Restrictions

required(VARIABLES, var)
$|\text{VARIABLES}| \geq 1$
$|\text{VALUES}| \geq 1$
required(VALUES, val)
distinct(VALUES, val)
required(SETS, set)
$|\text{SETS}| > 1$
non_increasing_size(SETS, set)
required(PARTITIONS, p)
$|\text{PARTITIONS}| \geq 2$

Purpose Given |SETS| sets of domain variables, the K_USED_BY_PARTITION constraint forces a USED_BY_PARTITION constraint between each pair of consecutive sets.

Example

$$\left(\begin{array}{l}\langle \texttt{set} - \langle 1,9,1,6,2,3\rangle, \texttt{set} - \langle 1,3,6,6\rangle, \texttt{set} - \langle 2,2\rangle\rangle, \\ \langle \texttt{p} - \langle 1,3\rangle, \texttt{p} - \langle 4\rangle, \texttt{p} - \langle 2,6\rangle\rangle\end{array}\right)$$

The K_USED_BY_PARTITION constraint holds since:

- The first collection of variables is assigned 3 values in $\{1,3\}$, 0 value in $\{4\}$ and 2 values in $\{2,6\}$, while the second collection of variables is assigned no more values in the previous three sets of values.
- The second collection of variables is assigned 2 values in $\{1,3\}$, 0 value in $\{4\}$ and 2 values in $\{2,6\}$, while the third collection of variables is assigned no more values in the previous three sets of values.

Typical $|\text{VARIABLES}| > 1$

Symmetries

- Items of SETS are permutable.
- Items of SETS.set are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of SETS.set.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Arg. properties

Contractible wrt. SETS.

5.218 LENGTH_FIRST_SEQUENCE

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Inspired by STRETCH_PATH

Constraint LENGTH_FIRST_SEQUENCE(LEN, VARIABLES)

Synonym LENGTH_FIRST_STRETCH.

Arguments

LEN	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

LEN ≥ 0
LEN $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose LEN is the length of the maximum sequence of variables that take the same value that contains the first variable of the collection VARIABLES (or 0 if the collection is empty).

Example

$(3, \langle 4, 4, 4, 5, 5, 4\rangle)$
$(6, \langle 4, 4, 4, 4, 4, 4\rangle)$
$(5, \langle 4, 4, 4, 4, 4, 1\rangle)$

4 4 4 5 5 4
4 4 4 4 4 4
4 4 4 4 4 1

The first LENGTH_FIRST_SEQUENCE constraint holds since the sequence associated with the first value of the collection VARIABLES $= \langle 4, 4, 4, 5, 5, 4\rangle$ spans over three consecutive variables.

Typical

LEN $<$ |VARIABLES|
|VARIABLES| > 1

Typical model nval(VARIABLES.var) > 2

Symmetry All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Functional dependency: LEN determined by VARIABLES.

Reformulation Without loss of generality let assume that the collection VARIABLES $= \langle V_1, V_2, \ldots, V_n\rangle$ has more than one variable. By introducing $2 \cdot n - 1$ 0-1 variables, the LENGTH_FIRST_SEQUENCE(LEN, VARIABLES) constraint can be expressed in term of $2 \cdot n - 1$ reified constraints and one arithmetic constraint (i.e., a SUM_CTR constraint). We first introduce $n-1$ variables that are respectively set to 1 if and only if two given consecutive variables of the collection VARIABLES are equal:

$B_{1,2} \quad \Leftrightarrow V_1 = V_2,$
$B_{2,3} \quad \Leftrightarrow V_2 = V_3,$

....
$B_{n-1,n} \Leftrightarrow V_{n-1} = V_n$.
We then introduce n variables $A_1, A_2, \ldots, A_n$ that are respectively associated to the different sliding sequences starting on the first variable of the sequence $V_1\ V_2\ \ldots\ V_n$. Variable A_i is set to 1 if and only if $V_1 = V_2 = \cdots = V_i$:
$A_1 = 1$,
$A_2 \Leftrightarrow B_{1,2} \quad \wedge A_1$,
$A_3 \Leftrightarrow B_{2,3} \quad \wedge A_2$,
....
$A_n \Leftrightarrow B_{n-1,n} \wedge A_{n-1}$.
Finally we state the following arithmetic constraint:
`LEN` $= A_1 + A_2 + \cdots + A_n$.

Counting

Figure 5.498: Automaton of the reverse of the LENGTH_FIRST_SEQUENCE constraint (i.e., the LENGTH_LAST_SEQUENCE constraint) when $|\mathtt{VARIABLES}| \geq 2$ and corresponding glue matrix between LENGTH_FIRST_SEQUENCE and its reverse LENGTH_LAST_SEQUENCE

5.219 LENGTH_LAST_SEQUENCE

DESCRIPTION LINKS AUTOMATON

Origin Inspired by STRETCH_PATH

Constraint LENGTH_LAST_SEQUENCE(LEN, VARIABLES)

Synonym LENGTH_LAST_STRETCH.

Arguments

LEN : dvar
VARIABLES : collection(var−dvar)

Restrictions

LEN ≥ 0
LEN $\leq |$VARIABLES$|$
required(VARIABLES, var)

Purpose LEN is the length of the maximum sequence of variables that take the same value that contains the last variable of the collection VARIABLES (or 0 if the collection is empty).

Example

$(1, \langle 4, 4, 4, 5, 5, 4\rangle)$
$(6, \langle 4, 4, 4, 4, 4, 4\rangle)$
$(5, \langle 2, 4, 4, 4, 4, 4\rangle)$

4 4 4 5 5 4
4 4 4 4 4 4
2 4 4 4 4 4

The first LENGTH_LAST_SEQUENCE constraint holds since the sequence associated with the last value of the collection VARIABLES $= \langle 4, 4, 4, 5, 5, 4\rangle$ spans over a single variable.

Typical

LEN $<|$VARIABLES$|$
$|$VARIABLES$| > 1$

Typical model nval(VARIABLES.var) > 2

Symmetry All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Functional dependency: LEN determined by VARIABLES.

Reformulation Without loss of generality let assume that the collection VARIABLES $= \langle V_1, V_2, \ldots, V_n\rangle$ has more than one variable. By introducing $2 \cdot n - 1$ 0-1 variables, the LENGTH_LAST_SEQUENCE(LEN, VARIABLES) constraint can be expressed in term of $2 \cdot n - 1$ reified constraints and one arithmetic constraint (i.e., a SUM_CTR constraint). We first introduce $n-1$ variables that are respectively set to 1 if and only if two given consecutive variables of the collection VARIABLES are equal:

$B_{n-1,n} \Leftrightarrow V_{n-1} = V_n,$
$B_{n-2,n-1} \Leftrightarrow V_{n-2} = V_{n-1},$

....
$B_{1,2} \quad \Leftrightarrow V_1 = V_2$.

We then introduce n variables $A_n, A_{n-1}, \ldots, A_1$ that are respectively associated to the different sliding sequences ending on the last variable of the sequence $V_1\ V_2\ \ldots\ V_n$. Variable A_i is set to 1 if and only if $V_n = V_{n-1} = \cdots = V_i$:

$A_n = 1$,
$A_{n-1} \Leftrightarrow B_{n-1,n} \quad \wedge A_n$,
$A_{n-2} \Leftrightarrow B_{n-2,n-1} \wedge A_{n-1}$,
....
$A_1 \quad \Leftrightarrow B_{1,2} \quad \wedge A_2$.

Finally we state the following arithmetic constraint:

$\texttt{LEN} = A_n + A_{n-1} + \cdots + A_1$.

Counting

Length (n)	2	3	4	5	6	7	8
Solutions	9	64	625	7776	117649	2097152	43046721

5.220 LEQ

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic.

Constraint LEQ(VAR1, VAR2)

Synonyms REL, XLTEQY.

Arguments

VAR1	:	dvar
VAR2	:	dvar

Purpose Enforce the fact that the first variable is less than or equal to the second variable.

Example $(1, 8)$

The LEQ constraint holds since 1 is greater than or equal to 8.

Symmetries

- VAR1 can be replaced by any value $\leq$ VAR2.
- VAR2 can be replaced by any value $\geq$ VAR1.

Systems LEQ in **Choco**, REL in **Gecode**, XLTEQY in **JaCoP**, #=< in **SICStus**.

See also

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

5.221 LEQ_CST

► ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint LEQ_CST(VAR1, VAR2, CST2)

Arguments

VAR1	:	dvar
VAR2	:	dvar
CST2	:	int

Purpose Enforce the fact that the first variable is less than or equal to the sum of the second variable and the constant.

Example $(5, 2, 4)$

The LEQ_CST constraint holds since 5 is less than or equal to $2 + 4$.

Typical

$\texttt{CST2} \neq 0$
$\texttt{VAR1} < \texttt{VAR2} + \texttt{CST2}$

Symmetries

- Arguments are permutable w.r.t. permutation (VAR1) (VAR2, CST2).
- VAR1 can be replaced by any value $\leq$ VAR2 + CST2.
- VAR2 can be replaced by any value $\geq$ VAR1 − CST2.
- CST2 can be replaced by any value $\geq$ VAR1 − VAR2.

5.222 LEX2

► ▷ ◁ ◄ **DESCRIPTION** **LINKS**

Origin [179]

Constraint LEX2(MATRIX)

Synonyms DOUBLE_LEX, ROW_AND_COLUMN_LEX.

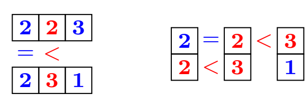
Type VECTOR : collection(var−dvar)

Argument MATRIX : collection(vec − VECTOR)

Restrictions
|VECTOR| ≥ 1
required(VECTOR, var)
required(MATRIX, vec)
same_size(MATRIX, vec)

Purpose Given a matrix of domain variables, enforces that both adjacent rows, and adjacent columns are lexicographically ordered (adjacent rows and adjacent columns can be equal).

Example $(\langle \texttt{vec} - \langle 2,2,3\rangle, \texttt{vec} - \langle 2,3,1\rangle\rangle)$



The LEX2 constraint holds since:

- The first row $\langle 2,2,3\rangle$ is lexicographically less than or equal to the second row $\langle 2,3,1\rangle$.
- The first column $\langle 2,2\rangle$ is lexicographically less than or equal to the second column $\langle 2,3\rangle$.
- The second column $\langle 2,3\rangle$ is lexicographically less than or equal to the third column $\langle 3,1\rangle$.

Typical
|VECTOR| > 1
|MATRIX| > 1

Symmetry One and the same constant can be added to the var attribute of all items of MATRIX.vec.

Usage A *symmetry-breaking* constraint.

Remark The idea of this *symmetry-breaking* constraint can already be found in the following articles of A. Lubiw [278, 279].

In block designs you sometimes want repeated blocks, so using the non-strict order would be required in this case.

Reformulation The LEX2 constraint can be expressed as a conjunction of two LEX_CHAIN_LESSEQ constraints: A first LEX_CHAIN_LESSEQ constraint on the MATRIX argument and a second LEX_CHAIN_LESSEQ constraint on the transpose of the MATRIX argument.

Systems LEX2 in **MiniZinc**.

See also **common keyword:** ALLPERM, LEX_LESSEQ *(matrix symmetry,lexicographic order)*.

implied by: STRICT_LEX2.

implies: LEX_CHAIN_LESSEQ.

part of system of constraints: LEX_CHAIN_LESSEQ.

Keywords **constraint type:** predefined constraint, system of constraints, order constraint.

modelling: matrix, matrix model.

symmetry: symmetry, matrix symmetry, lexicographic order.

5.223 LEX_ALLDIFFERENT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin J. Pearson

Constraint LEX_ALLDIFFERENT(VECTORS)

Synonyms LEX_ALLDIFF, LEX_ALLDISTINCT, ALLDIFF_ON_TUPLES, ALLDIFFERENT_ON_TUPLES, ALLDISTINCT_ON_TUPLES.

Type VECTOR : collection(var−dvar)

Argument VECTORS : collection(vec − VECTOR)

Restrictions
|VECTOR| ≥ 1
required(VECTOR, var)
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose All the vectors of the collection VECTORS are distinct. Two vectors $(u_1, u_2, \ldots, u_n)$ and $(v_1, v_2, \ldots, v_n)$ are distinct if and only if there exists $i \in [1, n]$ such that $u_i \neq v_i$.

Example $(\langle \texttt{vec} - \langle 5,2,3\rangle, \texttt{vec} - \langle 5,2,6\rangle, \texttt{vec} - \langle 5,3,3\rangle\rangle)$

The LEX_ALLDIFFERENT constraint holds since:

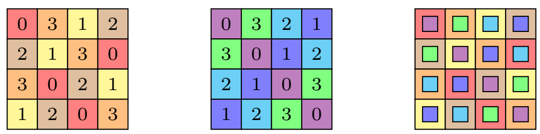
- The first vector $\langle 5,2,3\rangle$ and the second vector $\langle 5,2,6\rangle$ of the VECTORS collection differ in their third components (i.e., $3 \neq 6$).
- The first vector $\langle 5,2,3\rangle$ and the third vector $\langle 5,3,3\rangle$ of the VECTORS collection differ in their second components (i.e., $2 \neq 3$).
- The second vector $\langle 5,2,6\rangle$ and the third vector $\langle 5,3,3\rangle$ of the VECTORS collection differ in their second and third components (i.e., $2 \neq 3$ and $6 \neq 3$).

Typical
|VECTOR| > 1
|VECTORS| > 1

Symmetries
- Items of VECTORS are permutable.
- Items of VECTORS.vec are permutable (*same permutation used*).
- All occurrences of two distinct tuples of values of VECTORS.vec can be swapped; all occurrences of a tuple of values of VECTORS.vec can be renamed to any unused tuple of values.

Arg. properties
- Contractible wrt. VECTORS.
- Extensible wrt. VECTORS.vec (*add items at same position*).

Usage When the vectors have two components, the LEX_ALLDIFFERENT constraint allows to directly enforce difference constraints between pairs of variables. Such difference constraints occur, for example, in block design problems (e.g., Steiner triples, Kirkman schoolgirls, orthogonal Latin squares problems). However, in all these problems a same variable may occur in more than one pair of variables. Consequently, arc-consistency is not achieved any more by the filtering algorithm described in [346]. Figure 5.502 illustrates the use of the LEX_ALLDIFFERENT constraint in the context of the orthogonal Latin squares problem, i.e. two Latin squares such that the pairs of corresponding cells are distinct.



(A) First Latin square (B) Second Latin square (C) Corresponding orthogonal Latin square

$$\left(\left\langle\begin{array}{llll}
\texttt{vec} - \langle 0,0\rangle, & \texttt{vec} - \langle 3,3\rangle, & \texttt{vec} - \langle 1,2\rangle, & \texttt{vec} - \langle 2,1\rangle, \\
\texttt{vec} - \langle 2,3\rangle, & \texttt{vec} - \langle 1,0\rangle, & \texttt{vec} - \langle 3,1\rangle, & \texttt{vec} - \langle 0,2\rangle, \\
\texttt{vec} - \langle 3,2\rangle, & \texttt{vec} - \langle 0,1\rangle, & \texttt{vec} - \langle 2,0\rangle, & \texttt{vec} - \langle 1,3\rangle, \\
\texttt{vec} - \langle 1,1\rangle, & \texttt{vec} - \langle 2,2\rangle, & \texttt{vec} - \langle 0,3\rangle, & \texttt{vec} - \langle 3,0\rangle
\end{array}\right\rangle\right)$$

(D) Argument of the LEX_ALLDIFFERENT constraint enforcing that the pairs of corresponding cells are all distinct

Figure 5.502: Illustrating the use of the LEX_ALLDIFFERENT constraint in the context of orthogonal Latin squares

Algorithm A filtering algorithm achieving arc-consistency for the LEX_ALLDIFFERENT constraint is proposed by C.-G. Quimper and T. Walsh in [346] and a longer version is available in [347] and in [348].

Reformulation The LEX_ALLDIFFERENT(VECTORS) constraint can be expressed as a clique of LEX_DIFFERENT constraints. By associating a n-dimensional box for which all sizes are equal to 1, one can also express the LEX_ALLDIFFERENT(VECTORS) constraint as a DIFFN or a GEOST constraint. Enforcing all the n-dimensional boxes to not overlap is equivalent as enforcing all the vectors to be distinct. In the context of the multidimensional sweep algorithm of the GEOST constraint [42], it makes more sense to make a complete sweep over the domain of each variable in order not to only restrict the minimum and maximum value of each variable.

See also **generalisation:** DIFFN (`vector` *replaced by* `orthotope`), GEOST (`vector` *replaced by* `object`).

implied by: ALL_INCOMPARABLE, LEX_CHAIN_GREATER, LEX_CHAIN_LESS.

implies: LEX_ALLDIFFERENT_EXCEPT_0.

part of system of constraints: LEX_DIFFERENT.

specialisation: ALLDIFFERENT (`vector` *replaced by* `variable`).

used in graph description: LEX_DIFFERENT.

Keywords

characteristic of a constraint: vector.

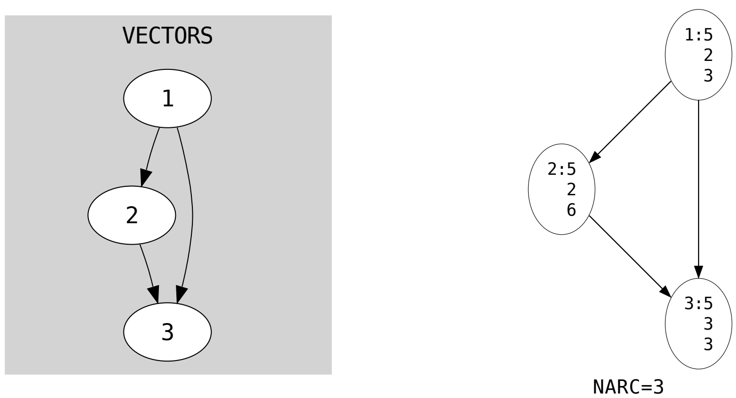
constraint type: system of constraints, decomposition.

filtering: bipartite matching, arc-consistency.

modelling: difference between pairs of variables.

Arc input(s)	VECTORS
Arc generator	$CLIQUE(<) \mapsto$ collection(vectors1, vectors2)
Arc arity	2
Arc constraint(s)	LEX_DIFFERENT(vectors1.vec, vectors2.vec)
Graph property(ies)	**NARC** $= |\texttt{VECTORS}| * (|\texttt{VECTORS}| - 1)/2$

Graph model Parts (A) and (B) of Figure 5.503 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.



(A) **(B)**

Figure 5.503: Initial and final graph of the LEX_ALLDIFFERENT constraint

Signature Since we use the $CLIQUE(<)$ arc generator on the VECTORS collection the number of arcs of the initial graph is equal to $|\texttt{VECTORS}| \cdot (|\texttt{VECTORS}| - 1)/2$. For this reason we can rewrite $\mathbf{NARC} = |\texttt{VECTORS}| \cdot (|\texttt{VECTORS}| - 1)/2$ to $\mathbf{NARC} \geq |\texttt{VECTORS}| \cdot (|\texttt{VECTORS}| - 1)/2$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.224 LEX_ALLDIFFERENT_EXCEPT_0

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin H. Simonis

Constraint LEX_ALLDIFFERENT_EXCEPT_0(VECTORS)

Synonyms LEX_ALLDIFF_EXCEPT_0, LEX_ALLDISTINCT_EXCEPT_0, ALLDIFF_ON_TUPLES_EXCEPT_0, ALLDIFFERENT_ON_TUPLES_EXCEPT_0, ALLDISTINCT_ON_TUPLES_EXCEPT_0.

Type VECTOR : collection(var−dvar)

Argument VECTORS : collection(vec − VECTOR)

Restrictions
$|\texttt{VECTOR}| \geq 1$
required(VECTOR, var)
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose All the non null vectors of the collection VECTORS are distinct. A vector is *null* if all its components are equal to zero. Two non null vectors $(u_1, u_2, \ldots, u_n)$ and $(v_1, v_2, \ldots, v_n)$ are *distinct* if and only if there exists $i \in [1, n]$ such that $u_i \neq v_i$.

Example

$$\left(\left\langle\begin{array}{l}\texttt{vec} - \langle 0,0,0\rangle,\\ \texttt{vec} - \langle 5,2,0\rangle,\\ \texttt{vec} - \langle 5,8,0\rangle,\\ \texttt{vec} - \langle 0,0,0\rangle\end{array}\right\rangle\right)$$

The LEX_ALLDIFFERENT_EXCEPT_0 constraint holds since its two non null vectors, i.e. the second and third vectors are distinct (the vectors $\langle 5, 2, 0\rangle$ and $\langle 5, 8, 0\rangle$ differ in their second components.

Typical
$|\texttt{VECTOR}| > 1$
$|\texttt{VECTORS}| > 1$

Arg. properties Contractible wrt. VECTORS.

See also **implied by:** LEX_ALLDIFFERENT.

Keywords **characteristic of a constraint:** vector, joker value.
constraint type: predefined constraint.
modelling: difference between pairs of variables.

5.225 LEX_BETWEEN

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin [104]

Constraint LEX_BETWEEN(LOWER_BOUND, VECTOR, UPPER_BOUND)

Synonym BETWEEN.

Arguments

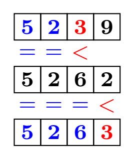
LOWER_BOUND	:	collection(var−int)
VECTOR	:	collection(var−dvar)
UPPER_BOUND	:	collection(var−int)

Restrictions

required(LOWER_BOUND, var)
required(VECTOR, var)
required(UPPER_BOUND, var)
$|$LOWER_BOUND$|$ = $|$VECTOR$|$
$|$UPPER_BOUND$|$ = $|$VECTOR$|$
LEX_LESSEQ(LOWER_BOUND, VECTOR)
LEX_LESSEQ(VECTOR, UPPER_BOUND)

Purpose The vector VECTOR is lexicographically greater than or equal to the fixed vector LOWER_BOUND and lexicographically smaller than or equal to the fixed vector UPPER_BOUND.

Example $(\langle 5, 2, 3, 9\rangle, \langle 5, 2, 6, 2\rangle, \langle 5, 2, 6, 3\rangle)$



The LEX_BETWEEN constraint holds since:

- The vector VECTOR = $\langle 5, 2, 6, 2\rangle$ is greater than or equal to the vector LOWER_BOUND = $\langle 5, 2, 3, 9\rangle$.
- The vector VECTOR = $\langle 5, 2, 6, 2\rangle$ is less than or equal to the vector UPPER_BOUND = $\langle 5, 2, 6, 3\rangle$.

Typical

$|$LOWER_BOUND$|$ > 1
LEX_LESSEQ(LOWER_BOUND, UPPER_BOUND)

Symmetries

- LOWER_BOUND.var can be decreased.
- UPPER_BOUND.var can be increased.

Arg. properties Suffix-contractible wrt. LOWER_BOUND, VECTOR and UPPER_BOUND (*remove items from same position*).

Usage This constraint does usually not occur explicitly in practice. However it shows up indirectly in the context of the LEX_CHAIN_LESS and the LEX_CHAIN_LESSEQ constraints: in order to have a complete filtering algorithm for the LEX_CHAIN_LESS and the LEX_CHAIN_LESSEQ constraints one has to come up with a complete filtering algorithm for the LEX_BETWEEN constraint. The reason is that the LEX_CHAIN_LESS as well as the LEX_CHAIN_LESSEQ constraints both compute feasible lower and upper bounds for each vector they mention. Therefore one ends up with a LEX_BETWEEN constraint for each vector of the LEX_CHAIN_LESS and LEX_CHAIN_LESSEQ constraints.

Algorithm [104].

Reformulation The LEX_BETWEEN(LOWER_BOUND, VECTORS, UPPER_BOUND) constraint can be expressed as the conjunction LEX_LESSEQ(LOWER_BOUND, VECTORS) $\wedge$ LEX_LESSEQ(VECTORS, UPPER_BOUND).

Systems LEXCHAINEQ in **Choco**, LEX_CHAIN in **SICStus**.

See also **common keyword:** LEX_CHAIN_GREATER, LEX_CHAIN_GREATEREQ, LEX_CHAIN_LESS, LEX_CHAIN_LESSEQ, LEX_GREATER, LEX_GREATEREQ, LEX_LESS *(lexicographic order)*.

part of system of constraints: LEX_LESSEQ.

Keywords **characteristic of a constraint:** vector, automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: order constraint, system of constraints.

filtering: arc-consistency.

symmetry: symmetry, lexicographic order.

Automaton Figure 5.504 depicts the automaton associated with the LEX_BETWEEN constraint. Let $\mathtt{L}_i$, $\mathtt{V}_i$ and $\mathtt{U}_i$ respectively be the var attributes of the i^{th} items of the LOWER_BOUND, the VECTOR and the UPPER_BOUND collections. To each triple $(\mathtt{L}_i, \mathtt{V}_i, \mathtt{U}_i)$ corresponds a signature variable S_i as well as the following signature constraint:

$(\mathtt{L}_i < \mathtt{V}_i) \wedge (\mathtt{V}_i < \mathtt{U}_i) \Leftrightarrow S_i = 0 \wedge$

$(\mathtt{L}_i < \mathtt{V}_i) \wedge (\mathtt{V}_i = \mathtt{U}_i) \Leftrightarrow S_i = 1 \wedge$

$(\mathtt{L}_i < \mathtt{V}_i) \wedge (\mathtt{V}_i > \mathtt{U}_i) \Leftrightarrow S_i = 2 \wedge$

$(\mathtt{L}_i = \mathtt{V}_i) \wedge (\mathtt{V}_i < \mathtt{U}_i) \Leftrightarrow S_i = 3 \wedge$

$(\mathtt{L}_i = \mathtt{V}_i) \wedge (\mathtt{V}_i = \mathtt{U}_i) \Leftrightarrow S_i = 4 \wedge$

$(\mathtt{L}_i = \mathtt{V}_i) \wedge (\mathtt{V}_i > \mathtt{U}_i) \Leftrightarrow S_i = 5 \wedge$

$(\mathtt{L}_i > \mathtt{V}_i) \wedge (\mathtt{V}_i < \mathtt{U}_i) \Leftrightarrow S_i = 6 \wedge$

$(\mathtt{L}_i > \mathtt{V}_i) \wedge (\mathtt{V}_i = \mathtt{U}_i) \Leftrightarrow S_i = 7 \wedge$

$(\mathtt{L}_i > \mathtt{V}_i) \wedge (\mathtt{V}_i > \mathtt{U}_i) \Leftrightarrow S_i = 8$.

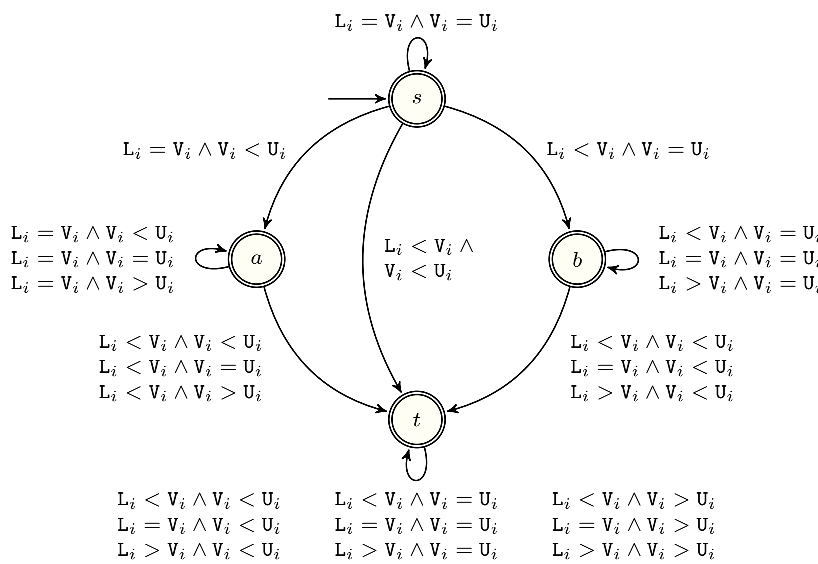


Figure 5.504: Automaton of the LEX_BETWEEN constraint

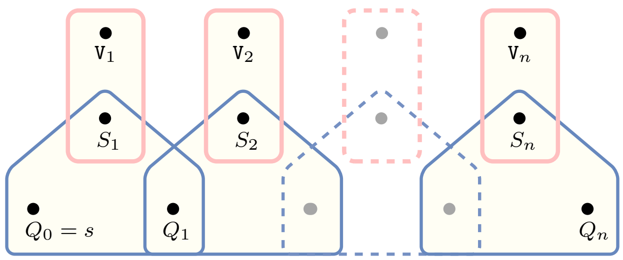

Figure 5.505: Hypergraph of the reformulation corresponding to the automaton of the LEX_BETWEEN constraint (since all states of the automaton are accepting there is no restriction on the last variable Q_n)

5.226 LEX_CHAIN_GREATER

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from LEX_CHAIN_LESS

Constraint LEX_CHAIN_GREATER(VECTORS)

Usual name LEX_CHAIN

Type VECTOR : collection(var−dvar)

Argument VECTORS : collection(vec − VECTOR)

Restrictions

$|\texttt{VECTOR}| \geq 1$
required(VECTOR, var)
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose

For each pair of consecutive vectors $\texttt{VECTOR}_i$ and $\texttt{VECTOR}_{i+1}$ of the VECTORS collection we have that $\texttt{VECTOR}_i$ is lexicographically strictly greater than $\texttt{VECTOR}_{i+1}$. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically strictly greater than* $\vec{Y}$ if and only if $X_0 > Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is lexicographically strictly greater than $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$(\langle \texttt{vec} - \langle 5, 2, 6, 3\rangle, \texttt{vec} - \langle 5, 2, 6, 2\rangle, \texttt{vec} - \langle 5, 2, 3, 9\rangle\rangle)$

5	2	6	3
=	=	=	>
5	2	6	2
=	=	>	
5	2	3	9

The LEX_CHAIN_GREATER constraint holds since:

- The first vector $\langle 5, 2, 6, 3\rangle$ of the VECTORS collection is lexicographically strictly greater than the second vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection.
- The second vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection is lexicographically strictly greater than the third vector $\langle 5, 2, 3, 9\rangle$ of the VECTORS collection.

Typical

$|\texttt{VECTOR}| > 1$
$|\texttt{VECTORS}| > 1$

Arg. properties

- Contractible wrt. VECTORS.
- Suffix-extensible wrt. VECTORS.vec (*add items at same position*).

Usage This constraint was motivated for breaking symmetry: more precisely when one wants to lexicographically order the consecutive columns of a matrix of decision variables. A further motivation is that using a set of lexicographic ordering constraints between two vectors does usually not allows the solver to come up with a complete pruning.

Algorithm A filtering algorithm achieving arc-consistency for a chain of lexicographical ordering constraints is presented in [104].

See also **common keyword:** LEX_BETWEEN, LEX_GREATEREQ, LEX_LESS, LEX_LESSEQ *(lexicographic order)*.

implies: LEX_ALLDIFFERENT, LEX_CHAIN_GREATEREQ.

part of system of constraints: LEX_GREATER.

used in graph description: LEX_GREATER.

Keywords **application area:** floor planning problem.

characteristic of a constraint: vector.

constraint type: decomposition, order constraint, system of constraints.

filtering: arc-consistency.

heuristics: heuristics and lexicographical ordering.

modelling: degree of diversity of a set of solutions.

modelling exercises: degree of diversity of a set of solutions.

symmetry: symmetry, matrix symmetry, lexicographic order.

Arc input(s)	VECTORS
Arc generator	$PATH \mapsto$ collection(vectors1, vectors2)
Arc arity	2
Arc constraint(s)	LEX_GREATER(vectors1.vec, vectors2.vec)
Graph property(ies)	$\mathbf{NARC} = \lvert\texttt{VECTORS}\rvert - 1$

Graph model Parts (A) and (B) of Figure 5.506 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold. The LEX_CHAIN_GREATER constraint holds since all the arc constraints of the initial graph are satisfied.

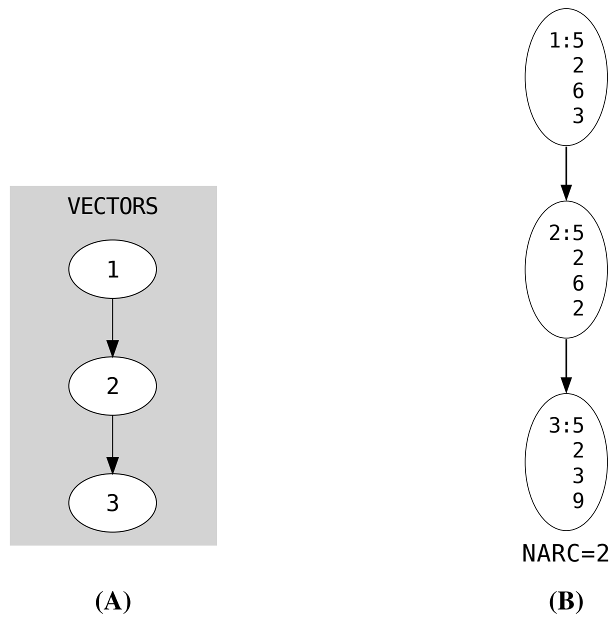

Figure 5.506: Initial and final graph of the LEX_CHAIN_GREATER constraint

Signature Since we use the $PATH$ arc generator on the VECTORS collection the number of arcs of the initial graph is equal to $\lvert\texttt{VECTORS}\rvert - 1$. For this reason we can rewrite $\mathbf{NARC} = \lvert\texttt{VECTORS}\rvert - 1$ to $\mathbf{NARC} \geq \lvert\texttt{VECTORS}\rvert - 1$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.227 LEX_CHAIN_GREATEREQ

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from LEX_CHAIN_LESSEQ

Constraint LEX_CHAIN_GREATEREQ(VECTORS)

Usual name LEX_CHAIN

Type VECTOR : collection(var−dvar)

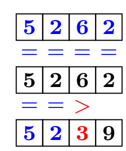
Argument VECTORS : collection(vec − VECTOR)

Restrictions
|VECTOR| ≥ 1
required(VECTOR, var)
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose For each pair of consecutive vectors $\texttt{VECTOR}_i$ and $\texttt{VECTOR}_{i+1}$ of the VECTORS collection we have that $\texttt{VECTOR}_i$ is lexicographically greater than or equal to $\texttt{VECTOR}_{i+1}$. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically greater than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 > Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is lexicographically greater than or equal to $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$$(\langle \texttt{vec} - \langle 5, 2, 6, 2\rangle, \texttt{vec} - \langle 5, 2, 6, 2\rangle, \texttt{vec} - \langle 5, 2, 3, 9\rangle\rangle)$$



The LEX_CHAIN_GREATEREQ constraint holds since:

- The first vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection is lexicographically greater than or equal to the second vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection.
- The second vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection is lexicographically greater than or equal to the third vector $\langle 5, 2, 3, 9\rangle$ of the VECTORS collection.

Typical
|VECTOR| > 1
|VECTORS| > 1

Arg. properties
- Contractible wrt. VECTORS.
- Suffix-contractible wrt. VECTORS.vec (*remove items from same position*).

Usage This constraint was motivated for breaking symmetry: more precisely when one wants to lexicographically order the consecutive columns of a matrix of decision variables. A further motivation is that using a set of lexicographic ordering constraints between two vectors does usually not allows the solver to come up with a complete pruning.

Algorithm

A filtering algorithm achieving arc-consistency for a chain of lexicographical ordering constraints is presented in [104].

Six different ways of integrating a chain of lexicographical ordering constraints within non-overlapping constraints like DIFFN or GEOST and within their corresponding necessary conditions like the CUMULATIVE constraint are shown in [3].

5.229 LEX_CHAIN_LESSEQ

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [104]

Constraint LEX_CHAIN_LESSEQ(VECTORS)

Usual name LEX_CHAIN

Type

VECTOR : collection(var−dvar)

Argument

VECTORS : collection(vec − VECTOR)

Restrictions

|VECTOR| ≥ 1
required(VECTOR, var)
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose

For each pair of consecutive vectors VECTOR_i and VECTOR_{i+1} of the VECTORS collection we have that VECTOR_i is lexicographically less than or equal to VECTOR_{i+1}. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically less than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is lexicographically less than or equal to $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$(\langle \text{vec} - \langle 5, 2, 3, 9\rangle, \text{vec} - \langle 5, 2, 6, 2\rangle, \text{vec} - \langle 5, 2, 6, 2\rangle\rangle)$

5	2	3	9
=	=	<	
5	2	6	2
=	=	=	=
5	2	6	2

The LEX_CHAIN_LESSEQ constraint holds since:

- The first vector $\langle 5, 2, 3, 9\rangle$ of the VECTORS collection is lexicographically less than or equal to the second vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection.
- The second vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection is lexicographically less than or equal to the third vector $\langle 5, 2, 6, 2\rangle$ of the VECTORS collection.

Typical

|VECTOR| > 1
|VECTORS| > 1

Arg. properties

(A) (B)

Figure 5.509: Initial and final graph of the LEX_CHAIN_LESSEQ constraint

Signature Since we use the $PATH$ arc generator on the VECTORS collection the number of arcs of the initial graph is equal to \|VECTORS\| − 1. For this reason we can rewrite $\mathbf{NARC}$ = \|VECTORS\| − 1 to $\mathbf{NARC} \geq$ \|VECTORS\| − 1 and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.230 LEX_DIFFERENT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Used for defining LEX_ALLDIFFERENT.

Constraint LEX_DIFFERENT(VECTOR1, VECTOR2)

Synonyms DIFFERENT, DIFF.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
$|\mathtt{VECTOR1}| > 0$
$|\mathtt{VECTOR1}| = |\mathtt{VECTOR2}|$

Purpose Vectors VECTOR1 and VECTOR2 differ in at least one component.

Example $(\langle 5, 2, 7, 1\rangle, \langle 5, 3, 7, 1\rangle)$

5	2	7	1
$=$	$\neq$	$=$	$=$
5	3	7	1

The LEX_DIFFERENT constraint holds since VECTOR1 $= \langle 5, 2, 7, 1\rangle$ and VECTOR2 $= \langle 5, 3, 7, 1\rangle$ differ in their second components.

Typical

$|\mathtt{VECTOR1}| > 1$
range(VECTOR1.var) > 1
range(VECTOR2.var) > 1

Symmetries

- Arguments are permutable w.r.t. permutation (VECTOR1, VECTOR2).
- Items of VECTOR1 and VECTOR2 are permutable (*same permutation used*).

Arg. properties Extensible wrt. VECTOR1 and VECTOR2 (*add items at same position*).

Reformulation The LEX_DIFFERENT$(\langle \mathtt{var} - U_1, \mathtt{var} - U_2, \dots, \mathtt{var} - U_{|\mathtt{VECTOR1}|}\rangle, \langle \mathtt{var} - V_1, \mathtt{var} - V_2, \dots, \mathtt{var} - V_{|\mathtt{VECTOR2}|}\rangle)$ constraint can be expressed in term of the following disjunction of disequality constraints $U_1 \neq V_1 \vee U_2 \neq V_2 \vee \dots \vee U_{|\mathtt{VECTOR1}|} \neq V_{|\mathtt{VECTOR2}|}$.

Used in LEX_ALLDIFFERENT, SORT_PERMUTATION.

5.231 LEX_EQUAL

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Initially introduced for defining NVECTOR

Constraint LEX_EQUAL(VECTOR1, VECTOR2)

Synonyms EQUAL, EQ.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
|VECTOR1| = |VECTOR2|

Purpose VECTOR1 is *equal to* VECTOR2. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 = Y_0 \wedge X_1 = Y_1 \wedge \cdots \wedge X_{n-1} = Y_{n-1}$.

Example $(\langle 1, 9, 1, 5\rangle, \langle 1, 9, 1, 5\rangle)$

1	9	1	5
=	=	=	=
1	9	1	5

The LEX_EQUAL constraint holds since (1) the first component of the first vector is equal to the first component of the second vector, (2) the second component of the first vector is equal to the second component of the second vector, (3) the third component of the first vector is equal to the third component of the second vector and (4) the fourth component of the first vector is equal to the fourth component of the second vector.

All solutions Figure 5.513 gives all solutions to the following non ground instance of the LEX_EQUAL constraint: $X_0 \in [1, 2]$, $X_1 \in [1, 2]$, $X_2 \in [1, 2]$, $Y_0 \in [0, 1]$, $Y_1 \in [0, 2]$, $Y_2 \in [2, 4]$, LEX_EQUAL0($\langle X_0, X_1, X_2\rangle, \langle Y_0, Y_1, Y_2\rangle$).

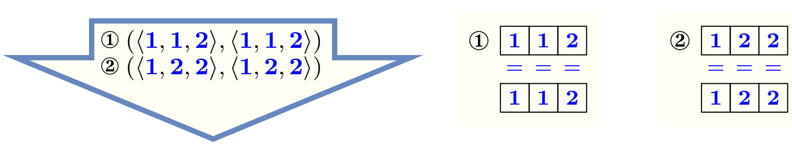

Figure 5.513: All solutions corresponding to the non ground example of the LEX_EQUAL constraint

Typical

|VECTOR1| > 1
range(VECTOR1.var) > 1
range(VECTOR2.var) > 1

Symmetries

- Arguments are permutable w.r.t. permutation (VECTOR1, VECTOR2).
- Items of VECTOR1 and VECTOR2 are permutable (*same permutation used*).

Arg. properties

Contractible wrt. VECTOR1 and VECTOR2 (*remove items from same position*).

Used in

ATLEAST_NVECTOR, ATMOST_NVECTOR, NVECTOR, NVECTORS.

5.232 LEX_GREATER

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint LEX_GREATER(VECTOR1, VECTOR2)

Synonyms LEX, LEX_CHAIN, REL, GREATER, GT.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
|VECTOR1| = |VECTOR2|

Purpose

VECTOR1 is *lexicographically strictly greater than* VECTOR2. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically strictly greater than* $\vec{Y}$ if and only if $X_0 > Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is *lexicographically strictly greater than* $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$(\langle 5, 2, 7, 1\rangle, \langle 5, 2, 6, 2\rangle)$

5	2	7	1
=	=	>	
5	2	6	2

The LEX_GREATER constraint holds since VECTOR1 $= \langle 5, 2, 7, 1\rangle$ is lexicographically strictly greater than VECTOR2 $= \langle 5, 2, 6, 2\rangle$.

All solutions

Figure 5.517 gives all solutions to the following non ground instance of the LEX_GREATER constraint: $X_0 \in [0, 1]$, $X_1 \in [0, 2]$, $X_2 \in [1, 1]$, $Y_0 \in [0, 1]$, $Y_1 \in [1, 2]$, $Y_2 \in [4, 4]$, LEX_GREATER($\langle X_0, X_1, X_2\rangle$, $\langle Y_0, Y_1, Y_2\rangle$).

Typical

$$|\text{VECTOR1}| > 1$$
$$\vee \left(\begin{array}{l} |\text{VECTOR1}| < 5, \\ \text{nval}([\text{VECTOR1.var}, \text{VECTOR2.var}]) < 2 * |\text{VECTOR1}| \end{array} \right)$$
$$\vee \left(\begin{array}{l} \text{maxval}([\text{VECTOR1.var}, \text{VECTOR2.var}]) \leq 1, \\ 2 * |\text{VECTOR1}| - \text{MAX\_NVALUE}([\text{VECTOR1.var}, \text{VECTOR2.var}]) > 2 \end{array} \right)$$

Symmetries

- VECTOR1.var can be increased.
- VECTOR2.var can be decreased.

Arg. properties

Suffix-extensible wrt. VECTOR1 and VECTOR2 (*add items at same position*).

Remark

A *multiset ordering* constraint and its corresponding filtering algorithm are described in [185].

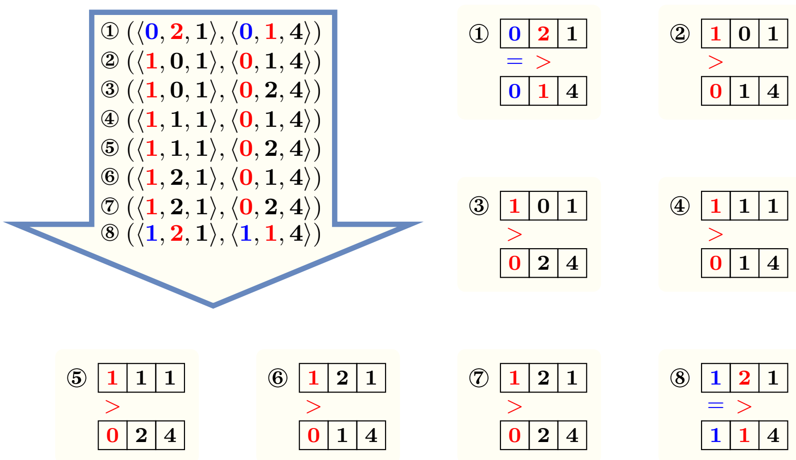

Figure 5.517: All solutions corresponding to the non ground example of the LEX_GREATER constraint

Algorithm The first filtering algorithm maintaining arc-consistency for this constraint was presented in [184]. A second filtering algorithm maintaining arc-consistency and detecting entailment in a more eager way, was given in [105]. This second algorithm was derived from a deterministic finite automata. A third filtering algorithm extending the algorithm presented in [184] detecting entailment is given in the PhD thesis of Z. Kızıltan [250, page 95]. The previous thesis [250, pages 105–109] presents also a filtering algorithm handling the fact that a given variable has more than one occurrence. Finally, T. Frühwirth shows how to encode lexicographic ordering constraints within the context of CHR [186] in [187].

Reformulation The following reformulations in term of arithmetic and/or logical expressions exist for enforcing the *lexicographically strictly greater than* constraint. The first one converts $\vec{X}$ and $\vec{Y}$ into numbers and post an inequality constraint. It assumes all components of $\vec{X}$ and $\vec{Y}$ to be within $[0, a-1]$:

$$a^{n-1}Y_0 + a^{n-2}Y_1 + \cdots + a^0 Y_{n-1} < a^{n-1}X_0 + a^{n-2}X_1 + \cdots + a^0 X_{n-1}$$

Since the previous reformulation can only be used with small values of n and a, W. Harvey came up with the following alternative model that maintains arc-consistency:

$$(Y_0 < X_0 + (Y_1 < X_1 + (\cdots + (Y_{n-1} < X_{n-1} + 0)\ldots))) = 1$$

Finally, the *lexicographically strictly greater than* constraint can be expressed as a conjunction or a disjunction of constraints:

$$
\begin{array}{rl}
Y_0 \leq X_0 & \wedge \\
(Y_0 = X_0) \Rightarrow Y_1 \leq X_1 & \wedge \\
(Y_0 = X_0 \wedge Y_1 = X_1) \Rightarrow Y_2 \leq X_2 & \wedge \\
\vdots & \\
(Y_0 = X_0 \wedge Y_1 = X_1 \wedge \cdots \wedge Y_{n-2} = X_{n-2}) \Rightarrow Y_{n-1} < X_{n-1} &
\end{array}
$$

$$
\begin{array}{rl}
Y_0 < X_0 & \vee \\
Y_0 = X_0 \wedge Y_1 < X_1 & \vee \\
Y_0 = X_0 \wedge Y_1 = X_1 \wedge Y_2 < X_2 & \vee \\
\vdots & \\
Y_0 = X_0 \wedge Y_1 = X_1 \wedge \cdots \wedge Y_{n-2} = X_{n-2} \wedge Y_{n-1} < X_{n-1} &
\end{array}
$$

When used separately, the two previous logical decompositions do not maintain arc-consistency.

$$\texttt{col}\left(\begin{array}{l}\texttt{COMPONENTS}-\texttt{collection}(\texttt{index}-\texttt{int},\texttt{x}-\texttt{dvar},\texttt{y}-\texttt{dvar}),\\ \left[\texttt{item}\left(\begin{array}{l}\texttt{index}-\texttt{VECTOR1.key},\\ \texttt{x}-\texttt{VECTOR1.var},\\ \texttt{y}-\texttt{VECTOR2.var}\end{array}\right)\right]\end{array}\right)$$

Arc input(s) COMPONENTS DESTINATION

Arc generator $PRODUCT(PATH, VOID) \mapsto \texttt{collection}(\texttt{item1},\texttt{item2})$

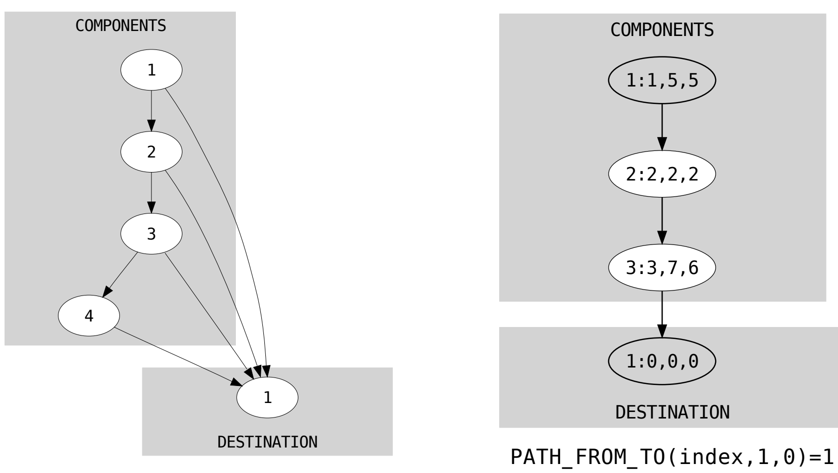
Arc arity 2

Arc constraint(s) $\bigvee\left(\begin{array}{l}\texttt{item2.index}>0\wedge\texttt{item1.x}=\texttt{item1.y},\\ \texttt{item2.index}=0\wedge\texttt{item1.x}>\texttt{item1.y}\end{array}\right)$

Graph property(ies) $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0)=1$

Graph model Parts (A) and (B) of Figure 5.518 respectively show the initial and final graph associated with the **Example** slot. Since we use the **PATH_FROM_TO** graph property we show the following information on the final graph:

- The vertices, which respectively correspond to the start and the end of the required path, are stressed in bold.
- The arcs on the required path are also stressed in bold.



(A) **(B)**

Figure 5.518: Initial and final graph of the LEX_GREATER constraint

The vertices of the initial graph are generated in the following way:

- We create a vertex c_i for each pair of components that both have the same index i.

- We create an additional dummy vertex called d.

The arcs of the initial graph are generated in the following way:

- We create an arc between c_i and d. We associate to this arc the arc constraint $\mathtt{item}_1.x > \mathtt{item}_2.y$.
- We create an arc between c_i and c_{i+1}. We associate to this arc the arc constraint $\mathtt{item}_1.x = \mathtt{item}_2.y$.

The LEX_GREATER constraint holds when there exist a path from c_1 to d. This path can be interpreted as a sequence of *equality* constraints on the prefix of both vectors, immediately followed by a *greater than* constraint.

Signature Since the maximum value returned by the graph property $\mathbf{PATH\_FROM\_TO}$ is equal to 1 we can rewrite $\mathbf{PATH\_FROM\_TO}(\mathtt{index}, 1, 0) = 1$ to $\mathbf{PATH\_FROM\_TO}(\mathtt{index}, 1, 0) \geq 1$. Therefore we simplify $\overline{\underline{\mathbf{PATH\_FROM\_TO}}}$ to $\overline{\mathbf{PATH\_FROM\_TO}}$.

Automaton Figure 5.519 depicts the automaton associated with the LEX_GREATER constraint. Let $\texttt{VAR1}_i$ and $\texttt{VAR2}_i$ respectively be the `var` attributes of the i^{th} items of the `VECTOR1` and the `VECTOR2` collections. To each pair $(\texttt{VAR1}_i, \texttt{VAR2}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\texttt{VAR1}_i < \texttt{VAR2}_i \Leftrightarrow S_i = 1) \wedge (\texttt{VAR1}_i = \texttt{VAR2}_i \Leftrightarrow S_i = 2) \wedge (\texttt{VAR1}_i > \texttt{VAR2}_i \Leftrightarrow S_i = 3)$.

5.233 LEX_GREATEREQ

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint LEX_GREATEREQ(VECTOR1, VECTOR2)

Synonyms LEXEQ, LEX_CHAIN, REL, GREATEREQ, GEQ, LEX_GEQ.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
|VECTOR1| = |VECTOR2|

Purpose

VECTOR1 is *lexicographically greater than or equal to* VECTOR2. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \dots, X_{n-1}\rangle$ and $\langle Y_0, \dots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically greater than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 > Y_0$ or $X_0 = Y_0$ and $\langle X_1, \dots, X_{n-1}\rangle$ is *lexicographically greater than or equal to* $\langle Y_1, \dots, Y_{n-1}\rangle$.

Example

$(\langle 5, 2, 8, 9\rangle, \langle 5, 2, 6, 2\rangle)$
$(\langle 5, 2, 3, 9\rangle, \langle 5, 2, 3, 9\rangle)$

5	2	8	9
=	=	>	
5	2	6	2

5	2	3	9
=	=	=	=
5	2	3	9

The LEX_GREATEREQ constraints associated with the first and second examples hold since:

- Within the first example VECTOR1 $= \langle 5, 2, 8, 9\rangle$ is lexicographically greater than or equal to VECTOR2 $= \langle 5, 2, 6, 2\rangle$.
- Within the second example VECTOR1 $= \langle 5, 2, 3, 9\rangle$ is lexicographically greater than or equal to VECTOR2 $= \langle 5, 2, 3, 9\rangle$.

All solutions

Figure 5.521 gives all solutions to the following non ground instance of the LEX_GREATEREQ constraint: $X_0 \in [0, 1]$, $X_1 \in [0, 2]$, $X_2 \in [1, 1]$, $Y_0 \in [1, 2]$, $Y_1 \in [1, 2]$, $Y_2 \in [1, 2]$, LEX_GREATEREQ0$(\langle X_0, X_1, X_2\rangle, \langle Y_0, Y_1, Y_2\rangle)$.

Typical

$$|\text{VECTOR1}| > 1$$
$$\vee \left(\begin{array}{l} |\text{VECTOR1}| < 5, \\ \text{nval}([\text{VECTOR1.var}, \text{VECTOR2.var}]) < 2 * |\text{VECTOR1}| \end{array} \right)$$
$$\vee \left(\begin{array}{l} \text{maxval}([\text{VECTOR1.var}, \text{VECTOR2.var}]) \leq 1, \\ 2 * |\text{VECTOR1}| - \text{MAX\_NVALUE}([\text{VECTOR1.var}, \text{VECTOR2.var}]) > 2 \end{array} \right)$$

Symmetries

- VECTOR1.var can be increased.
- VECTOR2.var can be decreased.

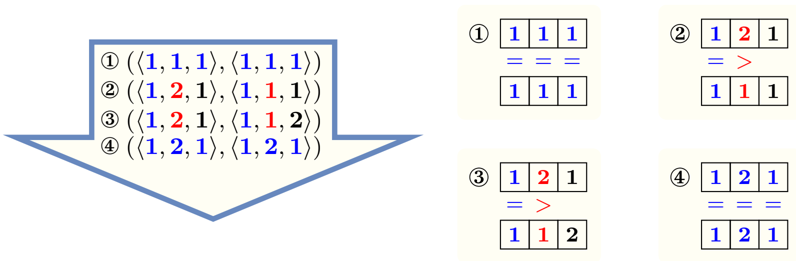

Figure 5.521: All solutions corresponding to the non ground example of the LEX_GREATEREQ constraint

Arg. properties Suffix-contractible wrt. `VECTOR1` and `VECTOR2` (*remove items from same position*).

Remark A *multiset ordering* constraint and its corresponding filtering algorithm are described in [185].

Algorithm The first filtering algorithm maintaining arc-consistency for this constraint was presented in [184]. A second filtering algorithm maintaining arc-consistency and detecting entailment in a more eager way, was given in [105]. This second algorithm was derived from a deterministic finite automata. A third filtering algorithm extending the algorithm presented in [184] detecting entailment is given in the PhD thesis of Z. Kızıltan [250, page 95]. The previous thesis [250, pages 105–109] presents also a filtering algorithm handling the fact that a given variable has more than one occurrence. Finally, T. Frühwirth shows how to encode lexicographic ordering constraints within the context of CHR [186] in [187].

Reformulation The following reformulations in term of arithmetic and/or logical expressions exist for enforcing the *lexicographically greater than or equal to* constraint. The first one converts $\vec{X}$ and $\vec{Y}$ into numbers and post an inequality constraint. It assumes all components of $\vec{X}$ and $\vec{Y}$ to be within $[0, a-1]$:

$$a^{n-1}Y_0 + a^{n-2}Y_1 + \cdots + a^0 Y_{n-1} \leq a^{n-1}X_0 + a^{n-2}X_1 + \cdots + a^0 X_{n-1}$$

Since the previous reformulation can only be used with small values of n and a, W. Harvey came up with the following alternative model that maintains arc-consistency:

$$(Y_0 < X_0 + (Y_1 < X_1 + (\cdots + (Y_{n-1} < X_{n-1} + 1)\ldots))) = 1$$

Finally, the *lexicographically greater than or equal to* constraint can be expressed as a conjunction or a disjunction of constraints:

$$\begin{array}{rl} Y_0 \leq X_0 & \wedge \\ (Y_0 = X_0) \Rightarrow Y_1 \leq X_1 & \wedge \\ (Y_0 = X_0 \wedge Y_1 = X_1) \Rightarrow Y_2 \leq X_2 & \wedge \\ \vdots & \\ (Y_0 = X_0 \wedge Y_1 = X_1 \wedge \cdots \wedge Y_{n-2} = X_{n-2}) \Rightarrow Y_{n-1} \leq X_{n-1} & \end{array}$$

$$\begin{array}{rl} Y_0 < X_0 & \vee \\ Y_0 = X_0 \wedge Y_1 < X_1 & \vee \\ Y_0 = X_0 \wedge Y_1 = X_1 \wedge Y_2 < X_2 & \vee \\ \vdots & \\ Y_0 = X_0 \wedge Y_1 = X_1 \wedge \cdots \wedge Y_{n-2} = X_{n-2} \wedge Y_{n-1} \leq X_{n-1} & \end{array}$$

When used separately, the two previous logical decompositions do not maintain arc-consistency.

Graph property(ies) $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0)=1$

Graph model

Parts (A) and (B) of Figure 5.522 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **PATH_FROM_TO** graph property we show on the final graph the following information:

- The vertices, which respectively correspond to the start and the end of the required path, are stressed in bold.
- The arcs on the required path are also stressed in bold.

The vertices of the initial graph are generated in the following way:

- We create a vertex c_i for each pair of components that both have the same index i.
- We create an additional dummy vertex called d.

The arcs of the initial graph are generated in the following way:

- We create an arc between c_i and d. When c_i was generated from the last components of both vectors We associate to this arc the arc constraint $\texttt{item}_1.x\geq\texttt{item}_2.y$; Otherwise we associate to this arc the arc constraint $\texttt{item}_1.x>\texttt{item}_2.y$;
- We create an arc between c_i and c_{i+1}. We associate to this arc the arc constraint $\texttt{item}_1.x=\texttt{item}_2.y$.

The LEX_GREATEREQ constraint holds when there exist a path from c_1 to d. This path can be interpreted as a maximum sequence of *equality* constraints on the prefix of both vectors, possibly followed by a *greater than* constraint.

Signature

Since the maximum value returned by the graph property **PATH_FROM_TO** is equal to 1 we can rewrite $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0)=1$ to $\underline{\mathbf{PATH\_FROM\_TO}}(\texttt{index},1,0)\geq 1$. Therefore we simplify $\underline{\overline{\mathbf{PATH\_FROM\_TO}}}$ to $\mathbf{PATH\_FROM\_TO}$.

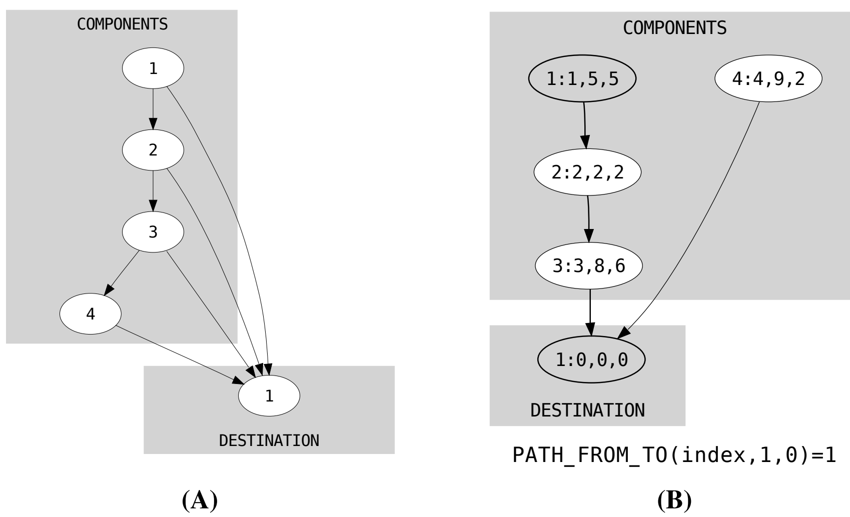

Figure 5.522: Initial and final graph of the LEX_GREATEREQ constraint

Automaton

Figure 5.523 depicts the automaton associated with the LEX_GREATEREQ constraint. Let VAR1_i and VAR2_i respectively be the var attributes of the i^{th} items of the VECTOR1 and the VECTOR2 collections. To each pair $(\text{VAR1}_i, \text{VAR2}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\text{VAR1}_i < \text{VAR2}_i \Leftrightarrow S_i = 1) \wedge (\text{VAR1}_i = \text{VAR2}_i \Leftrightarrow S_i = 2) \wedge (\text{VAR1}_i > \text{VAR2}_i \Leftrightarrow S_i = 3)$.

5.234 LEX_LESS

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint LEX_LESS(VECTOR1, VECTOR2)

Synonyms LEX, LEX_CHAIN, REL, LESS.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
|VECTOR1| = |VECTOR2|

Purpose VECTOR1 is *lexicographically strictly less than* VECTOR2. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically strictly less than* $\vec{Y}$ if and only if $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is *lexicographically strictly less than* $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example $(\langle 5,2,3,9\rangle, \langle 5,2,6,2\rangle)$

5	2	3	9
=	=	<	
5	2	6	2

The LEX_LESS constraint holds since VECTOR1 $= \langle 5,2,3,9\rangle$ is lexicographically strictly less than VECTOR2 $= \langle 5,2,6,2\rangle$.

All solutions Figure 5.525 gives all solutions to the following non ground instance of the LEX_LESS constraint: $X_0 \in [0,1]$, $X_1 \in [1,2]$, $X_2 \in [4,4]$, $Y_0 \in [0,1]$, $Y_1 \in [0,2]$, $Y_2 \in [1,1]$, LEX_LESS($\langle X_0, X_1, X_2\rangle$, $\langle Y_0, Y_1, Y_2\rangle$).

Typical

$$|\texttt{VECTOR1}| > 1$$
$$\vee \left(\begin{array}{l} |\texttt{VECTOR1}| < 5, \\ \texttt{nval}([\texttt{VECTOR1.var}, \texttt{VECTOR2.var}]) < 2 * |\texttt{VECTOR1}| \end{array} \right)$$
$$\vee \left(\begin{array}{l} \texttt{maxval}([\texttt{VECTOR1.var}, \texttt{VECTOR2.var}]) \leq 1, \\ 2 * |\texttt{VECTOR1}| - \text{MAX\_NVALUE}([\texttt{VECTOR1.var}, \texttt{VECTOR2.var}]) > 2 \end{array} \right)$$

Symmetries

- VECTOR1.var can be decreased.
- VECTOR2.var can be increased.

Arg. properties Suffix-extensible wrt. VECTOR1 and VECTOR2 (*add items at same position*).

Remark A *multiset ordering* constraint and its corresponding filtering algorithm are described in [185].

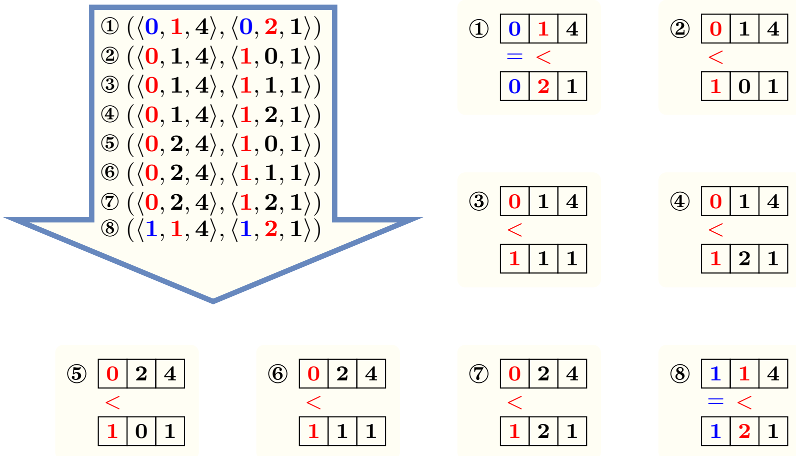

Figure 5.525: All solutions corresponding to the non ground example of the LEX_LESS constraint

Algorithm The first filtering algorithm maintaining arc-consistency for this constraint was presented in [184]. A second filtering algorithm maintaining arc-consistency and detecting entailment in a more eager way, was given in [105]. This second algorithm was derived from a deterministic finite automata. A third filtering algorithm extending the algorithm presented in [184] detecting entailment is given in the PhD thesis of Z. Kızıltan [250, page 95]. The previous thesis [250, pages 105–109] presents also a filtering algorithm handling the fact that a given variable has more than one occurrence. Finally, T. Frühwirth shows how to encode lexicographic ordering constraints within the context of CHR [186] in [187].

Reformulation The following reformulations in term of arithmetic and/or logical expressions exist for enforcing the *lexicographically strictly less than* constraint. The first one converts $\vec{X}$ and $\vec{Y}$ into numbers and post an inequality constraint. It assumes all components of $\vec{X}$ and $\vec{Y}$ to be within $[0, a-1]$:

$$a^{n-1}X_0 + a^{n-2}X_1 + \cdots + a^0X_{n-1} < a^{n-1}Y_0 + a^{n-2}Y_1 + \cdots + a^0Y_{n-1}$$

Since the previous reformulation can only be used with small values of n and a, W. Harvey came up with the following alternative model that maintains arc-consistency:

$$(X_0 < Y_0 + (X_1 < Y_1 + (\cdots + (X_{n-1} < Y_{n-1} + 0)\ldots))) = 1$$

Finally, the *lexicographically strictly less than* constraint can be expressed as a conjunction or a disjunction of constraints:

$$\begin{array}{rl} X_0 \le Y_0 & \wedge \\ (X_0 = Y_0) \Rightarrow X_1 \le Y_1 & \wedge \\ (X_0 = Y_0 \wedge X_1 = Y_1) \Rightarrow X_2 \le Y_2 & \wedge \\ \vdots & \\ (X_0 = Y_0 \wedge X_1 = Y_1 \wedge \cdots \wedge X_{n-2} = Y_{n-2}) \Rightarrow X_{n-1} < Y_{n-1} & \end{array}$$

$$\begin{array}{rl} X_0 < Y_0 & \vee \\ X_0 = Y_0 \wedge X_1 < Y_1 & \vee \\ X_0 = Y_0 \wedge X_1 = Y_1 \wedge X_2 < Y_2 & \vee \\ \vdots & \\ X_0 = Y_0 \wedge X_1 = Y_1 \wedge \cdots \wedge X_{n-2} = Y_{n-2} \wedge X_{n-1} < Y_{n-1} & \end{array}$$

When used separately, the two previous logical decompositions do not maintain arc-consistency.

implies: LEX_DIFFERENT, LEX_LESSEQ.

implies (if swap arguments): LEX_GREATER.

negation: LEX_GREATEREQ.

system of constraints: LEX_CHAIN_LESS.

Keywords **characteristic of a constraint:** vector, automaton, automaton without counters, reified automaton constraint, derived collection.

constraint arguments: constraint between two collections of variables.

constraint network structure: Berge-acyclic constraint network.

constraint type: order constraint.

filtering: duplicated variables, arc-consistency.

heuristics: heuristics and lexicographical ordering.

symmetry: symmetry, matrix symmetry, lexicographic order, multiset ordering.

Derived Collections

$$\texttt{col}\left(\begin{array}{l}\texttt{DESTINATION}-\texttt{collection}(\texttt{index}-\texttt{int},\texttt{x}-\texttt{int},\texttt{y}-\texttt{int}),\\ [\texttt{item}(\texttt{index}-0,\texttt{x}-0,\texttt{y}-0)]\end{array}\right)$$

$$\texttt{col}\left(\begin{array}{l}\texttt{COMPONENTS}-\texttt{collection}(\texttt{index}-\texttt{int},\texttt{x}-\texttt{dvar},\texttt{y}-\texttt{dvar}),\\ \left[\texttt{item}\left(\begin{array}{l}\texttt{index}-\texttt{VECTOR1.key},\\ \texttt{x}-\texttt{VECTOR1.var},\\ \texttt{y}-\texttt{VECTOR2.var}\end{array}\right)\right]\end{array}\right)$$

Arc input(s) COMPONENTS DESTINATION

Arc generator $PRODUCT(PATH, VOID) \mapsto \texttt{collection}(\texttt{item1},\texttt{item2})$

Arc arity 2

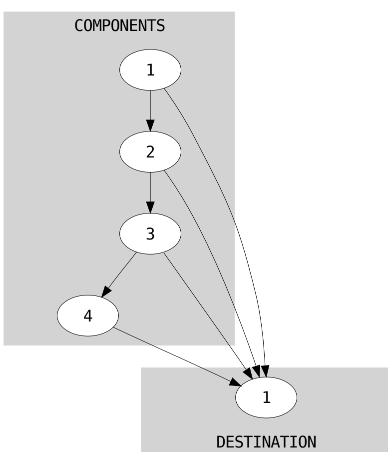
Arc constraint(s)

$$\bigvee\left(\begin{array}{l}\texttt{item2.index} > 0 \wedge \texttt{item1.x} = \texttt{item1.y},\\ \texttt{item2.index} = 0 \wedge \texttt{item1.x} < \texttt{item1.y}\end{array}\right)$$

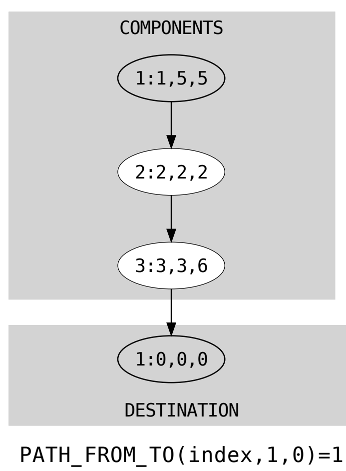
Graph property(ies) $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0) = 1$

Graph model Parts (A) and (B) of Figure 5.526 respectively show the initial and final graph associated with the **Example** slot. Since we use the **PATH_FROM_TO** graph property we show on the final graph the following information:

- The vertices, which respectively correspond to the start and the end of the required path, are stressed in bold.
- The arcs on the required path are also stressed in bold.



(A)



(B)

Figure 5.526: Initial and final graph of the LEX_LESS constraint

The vertices of the initial graph are generated in the following way:

- We create a vertex c_i for each pair of components that both have the same index i.

- We create an additional dummy vertex called d.

The arcs of the initial graph are generated in the following way:

- We create an arc between c_i and d. We associate to this arc the arc constraint $\texttt{item}_1.x < \texttt{item}_2.y$.
- We create an arc between c_i and c_{i+1}. We associate to this arc the arc constraint $\texttt{item}_1.x = \texttt{item}_2.y$.

The LEX_LESS constraint holds when there exist a path from c_1 to d. This path can be interpreted as a sequence of *equality* constraints on the prefix of both vectors, immediately followed by a *less than* constraint.

Signature

Since the maximum value returned by the graph property $\mathbf{PATH\_FROM\_TO}$ is equal to 1 we can rewrite $\mathbf{PATH\_FROM\_TO}(\texttt{index}, 1, 0) = 1$ to $\mathbf{PATH\_FROM\_TO}(\texttt{index}, 1, 0) \geq 1$. Therefore we simplify $\underline{\overline{\mathbf{PATH\_FROM\_TO}}}$ to $\overline{\mathbf{PATH\_FROM\_TO}}$.

Automaton Figure 5.527 depicts the automaton associated with the LEX_LESS constraint. Let $\texttt{VAR1}_i$ and $\texttt{VAR2}_i$ respectively be the var attributes of the i^{th} items of the VECTOR1 and the VECTOR2 collections. To each pair $(\texttt{VAR1}_i, \texttt{VAR2}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\texttt{VAR1}_i < \texttt{VAR2}_i \Leftrightarrow S_i = 1) \wedge (\texttt{VAR1}_i = \texttt{VAR2}_i \Leftrightarrow S_i = 2) \wedge (\texttt{VAR1}_i > \texttt{VAR2}_i \Leftrightarrow S_i = 3)$.

5.235 LEX_LESSEQ

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint LEX_LESSEQ(VECTOR1, VECTOR2)

Synonyms LEXEQ, LEX_CHAIN, REL, LESSEQ, LEQ, LEX_LEQ.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

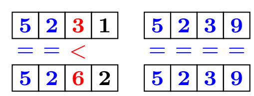
required(VECTOR1, var)
required(VECTOR2, var)
|VECTOR1| = |VECTOR2|

Purpose

VECTOR1 is *lexicographically less than or equal to* VECTOR2. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically less than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is *lexicographically less than or equal to* $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$(\langle 5, 2, 3, 1\rangle, \langle 5, 2, 6, 2\rangle)$
$(\langle 5, 2, 3, 9\rangle, \langle 5, 2, 3, 9\rangle)$



The LEX_LESSEQ constraints associated with the first and second examples hold since:

- Within the first example VECTOR1 $= \langle 5, 2, 3, 1\rangle$ is lexicographically less than or equal to VECTOR2 $= \langle 5, 2, 6, 2\rangle$.
- Within the second example VECTOR1 $= \langle 5, 2, 3, 9\rangle$ is lexicographically less than or equal to VECTOR2 $= \langle 5, 2, 3, 9\rangle$.

All solutions

Figure 5.529 gives all solutions to the following non ground instance of the LEX_LESSEQ constraint: $X_0 \in [1, 2]$, $X_1 \in [1, 2]$, $X_2 \in [1, 2]$, $Y_0 \in [0, 1]$, $Y_1 \in [0, 2]$, $Y_2 \in [1, 1]$, LEX_LESSEQ$(\langle X_0, X_1, X_2\rangle, \langle Y_0, Y_1, Y_2\rangle)$.

Typical

$$|\mathtt{VECTOR1}| > 1$$
$$\vee \left(\begin{array}{l}|\mathtt{VECTOR1}| < 5,\\ \mathrm{nval}([\mathtt{VECTOR1.var}, \mathtt{VECTOR2.var}]) < 2 * |\mathtt{VECTOR1}|\end{array}\right)$$
$$\vee \left(\begin{array}{l}\mathrm{maxval}([\mathtt{VECTOR1.var}, \mathtt{VECTOR2.var}]) \leq 1,\\ 2 * |\mathtt{VECTOR1}| - \mathrm{MAX\_NVALUE}([\mathtt{VECTOR1.var}, \mathtt{VECTOR2.var}]) > 2\end{array}\right)$$

Symmetries

- VECTOR1.var can be decreased.
- VECTOR2.var can be increased.

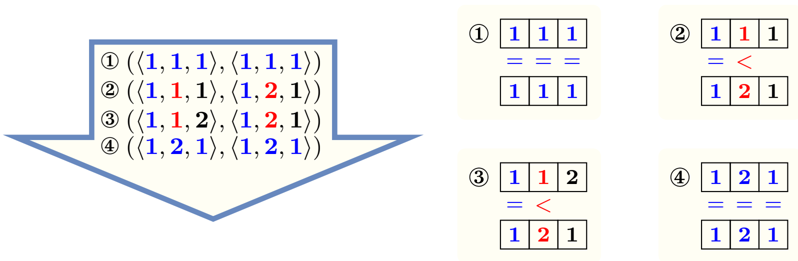


Figure 5.529: All solutions corresponding to the non ground example of the LEX_LESSEQ constraint

Arg. properties

Suffix-contractible wrt. VECTOR1 and VECTOR2 (*remove items from same position*).

Remark

A *multiset ordering* constraint and its corresponding filtering algorithm are described in [185].

Algorithm

The first filtering algorithm maintaining arc-consistency for this constraint was presented in [184]. A second filtering algorithm maintaining arc-consistency and detecting entailment in a more eager way, was given in [105]. This second algorithm was derived from a deterministic finite automata. A third filtering algorithm extending the algorithm presented in [184] detecting entailment is given in the PhD thesis of Z. Kızıltan [250, page 95]. The previous thesis [250, pages 105–109] presents also a filtering algorithm handling the fact that a given variable has more than one occurrence. Finally, T. Frühwirth shows how to encode lexicographic ordering constraints within the context of CHR [186] in [187].

Reformulation

The following reformulations in term of arithmetic and/or logical expressions exist for enforcing the *lexicographically less than or equal to* constraint. The first one converts $\vec{X}$ and $\vec{Y}$ into numbers and post an inequality constraint. It assumes all components of $\vec{X}$ and $\vec{Y}$ to be within $[0, a-1]$:

$$a^{n-1}X_0 + a^{n-2}X_1 + \cdots + a^0 X_{n-1} \leq a^{n-1}Y_0 + a^{n-2}Y_1 + \cdots + a^0 Y_{n-1}$$

Since the previous reformulation can only be used with small values of n and a, W. Harvey came up with the following alternative model that maintains arc-consistency:

$$(X_0 < Y_0 + (X_1 < Y_1 + (\cdots + (X_{n-1} < Y_{n-1} + 1)\ldots))) = 1$$

Finally, the *lexicographically less than or equal to* constraint can be expressed as a conjunction or a disjunction of constraints:

$$\begin{array}{rl} X_0 \leq Y_0 & \wedge \\ (X_0 = Y_0) \Rightarrow X_1 \leq Y_1 & \wedge \\ (X_0 = Y_0 \wedge X_1 = Y_1) \Rightarrow X_2 \leq Y_2 & \wedge \\ \vdots & \\ (X_0 = Y_0 \wedge X_1 = Y_1 \wedge \cdots \wedge X_{n-2} = Y_{n-2}) \Rightarrow X_{n-1} \leq Y_{n-1} & \end{array}$$

$$\begin{array}{rl} X_0 < Y_0 & \vee \\ X_0 = Y_0 \wedge X_1 < Y_1 & \vee \\ X_0 = Y_0 \wedge X_1 = Y_1 \wedge X_2 < Y_2 & \vee \\ \vdots & \\ X_0 = Y_0 \wedge X_1 = Y_1 \wedge \cdots \wedge X_{n-2} = Y_{n-2} \wedge X_{n-1} \leq Y_{n-1} & \end{array}$$

When used separately, the two previous logical decompositions do not maintain arc-consistency.

Graph property(ies) $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0)=1$

Graph model

Parts (A) and (B) of Figure 5.530 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **PATH_FROM_TO** graph property we show on the final graph the following information:

- The vertices, which respectively correspond to the start and the end of the required path, are stressed in bold.
- The arcs on the required path are also stressed in bold.

The vertices of the initial graph are generated in the following way:

- We create a vertex c_i for each pair of components that both have the same index i.
- We create an additional dummy vertex called d.

The arcs of the initial graph are generated in the following way:

- We create an arc between c_i and d. When c_i was generated from the last components of both vectors We associate to this arc the arc constraint $\texttt{item}_1.x \leq \texttt{item}_2.y$; Otherwise we associate to this arc the arc constraint $\texttt{item}_1.x < \texttt{item}_2.y$;
- We create an arc between c_i and c_{i+1}. We associate to this arc the arc constraint $\texttt{item}_1.x = \texttt{item}_2.y$.

The LEX_LESSEQ constraint holds when there exist a path from c_1 to d. This path can be interpreted as a maximum sequence of *equality* constraints on the prefix of both vectors, possibly followed by a *less than* constraint.

Signature

Since the maximum value returned by the graph property **PATH_FROM_TO** is equal to 1 we can rewrite $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0)=1$ to $\mathbf{PATH\_FROM\_TO}(\texttt{index},1,0)\geq 1$. Therefore we simplify $\underline{\overline{\mathbf{PATH\_FROM\_TO}}}$ to $\overline{\mathbf{PATH\_FROM\_TO}}$.

5.236 LEX_LESSEQ_ALLPERM

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Inspired by [179]

Constraint LEX_LESSEQ_ALLPERM(VECTOR1, VECTOR2)

Synonym LEXIMIN.

Arguments

VECTOR1 : collection(var−dvar)
VECTOR2 : collection(var−dvar)

Restrictions

required(VECTOR1, var)
required(VECTOR2, var)
|VECTOR1| = |VECTOR2|

Purpose VECTOR1 is *lexicographically less than or equal to* all permutations of VECTOR2. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically less than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is *lexicographically less than or equal to* $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example $(\langle 1,2,3\rangle, \langle 3,1,2\rangle)$

1 2 3	1 2 3	1 2 3	1 2 3	1 2 3	1 2 3
<	<	= <	= = =	<	<
3 1 2	3 2 1	1 3 2	1 2 3	2 1 3	2 3 1

The LEX_LESSEQ_ALLPERM constraint holds since vector $\langle 1,2,3\rangle$ is lexicographically less than or equal to all the permutations of vector $\langle 3,1,2\rangle$ (i.e., $\langle 1,2,3\rangle$, $\langle 1,3,2\rangle$, $\langle 2,1,3\rangle$, $\langle 2,3,1\rangle$, $\langle 3,1,2\rangle$, $\langle 3,2,1\rangle$).

Typical |VECTOR1| > 1

Symmetry All occurrences of two distinct values in VECTOR1.var or VECTOR2.var can be swapped; all occurrences of a value in VECTOR1.var or VECTOR2.var can be renamed to any unused value.

Arg. properties Suffix-contractible wrt. VECTOR1 and VECTOR2 (*remove items from same position*).

Remark The LEX_LESSEQ_ALLPERM(VECTOR1, VECTOR2) can be reformulated as the conjunction SORT(VECTOR2, VECTOR), LEX_LESSEQ(VECTOR1, VECTOR).

Systems LEXIMIN in **Choco**.

Used in ALLPERM.

See also **common keyword:** ALLPERM (*matrix symmetry*, *lexicographic order*).

implies: LEX_LESSEQ.

system of constraints: ALLPERM.

Keywords

characteristic of a constraint: vector.

constraint arguments: constraint between two collections of variables.

constraint type: predefined constraint, order constraint.

symmetry: symmetry, matrix symmetry, lexicographic order.

5.237 LINK_SET_TO_BOOLEANS

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Inspired by DOMAIN_CONSTRAINT.

Constraint LINK_SET_TO_BOOLEANS(SVAR, BOOLEANS)

Arguments

SVAR : svar
BOOLEANS : collection(bool−dvar, val−int)

Restrictions

required(BOOLEANS, [bool, val])
BOOLEANS.bool ≥ 0
BOOLEANS.bool ≤ 1
distinct(BOOLEANS, val)

Purpose Make the link between a set variable SVAR and those 0-1 variables that are associated with each potential value belonging to SVAR: The 0-1 variables, which are associated with a value belonging to the set variable SVAR, are equal to 1, while the remaining 0-1 variables are all equal to 0.

Example

$$\left(\begin{array}{l}\{1,3,4\},\\ \left\langle\begin{array}{ll}\texttt{bool}-0 & \texttt{val}-0,\\ \texttt{bool}-1 & \texttt{val}-1,\\ \texttt{bool}-0 & \texttt{val}-2,\\ \texttt{bool}-1 & \texttt{val}-3,\\ \texttt{bool}-1 & \texttt{val}-4,\\ \texttt{bool}-0 & \texttt{val}-5\end{array}\right\rangle\end{array}\right)$$

In the example, the 0-1 variables associated with the values 1, 3 and 4 are all set to 1, while the other 0-1 variables are set to 0. Consequently, the LINK_SET_TO_BOOLEANS constraint holds since its first argument SVAR is set to $\{1,3,4\}$.

Typical

$|\texttt{BOOLEANS}| > 1$
range(BOOLEANS.bool) > 1

Symmetry Items of BOOLEANS are permutable.

Usage This constraint is used in order to make the link between a formulation using set variables and a formulation based on linear programming.

Systems CHANNEL in **Gecode**, LINK_SET_TO_BOOLEANS in **MiniZinc**.

See also **common keyword:** ALLDIFFERENT_BETWEEN_SETS, CLIQUE *(constraint involving set variables)*, DOMAIN_CONSTRAINT *(channelling constraint)*, K_CUT, PATH_FROM_TO, ROOTS, STRONGLY_CONNECTED, SYMMETRIC_CARDINALITY, SYMMETRIC_GCC, TOUR *(constraint involving set variables)*.

Keywords

characteristic of a constraint: derived collection.

constraint arguments: constraint involving set variables.

constraint type: decomposition, value constraint.

filtering: linear programming.

modelling: channelling constraint, set channel.

Derived Collection

$$\mathtt{col}\left(\begin{array}{l}\mathtt{SET}-\mathtt{collection}(\mathtt{one}-\mathtt{int},\mathtt{setvar}-\mathtt{svar}),\\ [\mathtt{item}(\mathtt{one}-1,\mathtt{setvar}-\mathtt{SVAR})]\end{array}\right)$$

Arc input(s)	SET BOOLEANS
Arc generator	$PRODUCT \mapsto$ collection(set, booleans)
Arc arity	2
Arc constraint(s)	booleans.bool = set.one $\Leftrightarrow$ IN_SET(booleans.val, set.setvar)
Graph property(ies)	**NARC** = |BOOLEANS|

Graph model

The LINK_SET_TO_BOOLEANS constraint is modelled with the following bipartite graph. The first set of vertices corresponds to a single vertex containing the set variable. The second class of vertices contains one vertex for each item of the collection BOOLEANS. The arc constraint between the set variable SVAR and one potential value v of the set variable expresses the following:

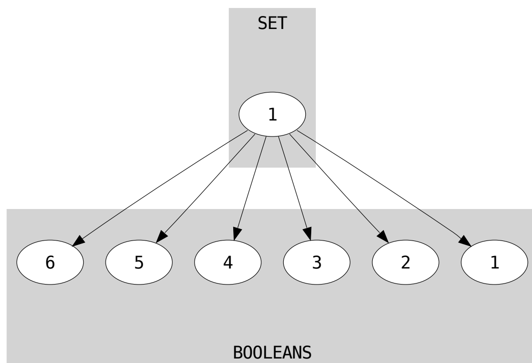
- If the 0-1 variable associated with v is equal to 1 then v should belong to SVAR.
- Otherwise if the 0-1 variable associated with v is equal to 0 then v should not belong to SVAR.

Since all arc constraints should hold the final graph contains exactly |BOOLEANS| arcs.

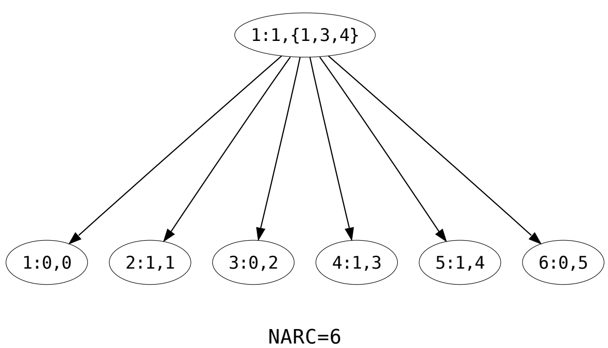
Parts (A) and (B) of Figure 5.533 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold. The LINK_SET_TO_BOOLEANS constraint holds since the final graph contains exactly 6 arcs (one for each 0-1 variable).

Signature

Since the initial graph contains |BOOLEANS| arcs the maximum number of arcs of the final graph is equal to |BOOLEANS|. Therefore we can rewrite the graph property **NARC** = |BOOLEANS| to **NARC** $\geq$ |BOOLEANS| and simplify $\underline{\mathbf{NARC}}$ to $\overline{\mathbf{NARC}}$.



(A)



(B)

Figure 5.533: Initial and final graph of the LINK_SET_TO_BOOLEANS constraint

5.238 LONGEST_CHANGE

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin

Derived from CHANGE.

Constraint

LONGEST_CHANGE(SIZE, VARIABLES, CTR)

Arguments

SIZE : dvar
VARIABLES : collection(var−dvar)
CTR : atom

Restrictions

SIZE ≥ 0
SIZE $\leq$ |VARIABLES|
required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose

SIZE is the maximum number of consecutive variables of the collection VARIABLES for which constraint CTR holds in an uninterrupted way (0 if the constraint CTR does not hold at all). We count a change when X CTR Y holds; X and Y are two consecutive variables of the collection VARIABLES.

Example

$(4, \langle 8, 8, 3, 4, 1, 1, 5, 5, 2\rangle, \neq)$

The LONGEST_CHANGE constraint holds since its first argument SIZE $= 4$ is fixed to the length of the longest subsequence of consecutive values of the collection $\langle 8, 8, 3, 4, 1, 1, 5, 5, 2\rangle$ such that two consecutive values are distinct (i.e., subsequence 8 3 4 1).

Typical

|VARIABLES| > 2
range(VARIABLES.var) > 1
CTR $\in [\neq]$

Symmetry

One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Functional dependency: SIZE determined by VARIABLES and CTR.

Arc generator	$PATH \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var CTR variables2.var
Graph property(ies)	$\mathbf{MAX\_NCC}$= SIZE

Graph model In order to specify the LONGEST_CHANGE constraint, we use $\mathbf{MAX\_NCC}$, which is the number of vertices of the largest connected component. Since the initial graph corresponds to a path, this will be the length of the longest path in the final graph.

Parts (A) and (B) of Figure 5.534 respectively show the initial and final graph associated with the **Example** slot. Since we use the $\mathbf{MAX\_NCC}$ graph property we show the largest connected component of the final graph. It corresponds to the longest period of uninterrupted changes: sequence $8, 3, 4, 1$ that involves 4 consecutive variables.

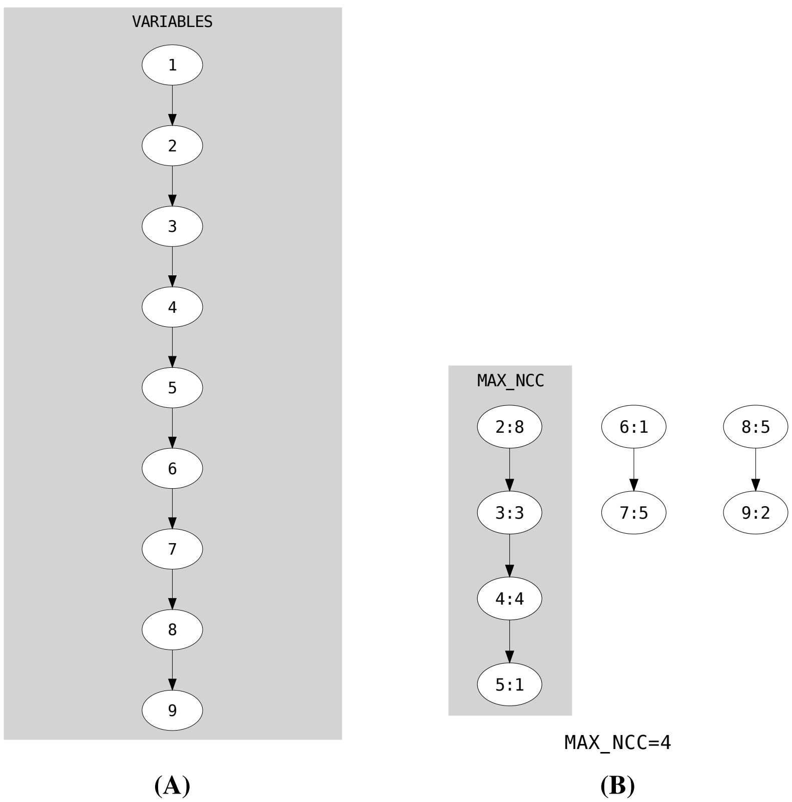

Figure 5.534: Initial and final graph of the LONGEST_CHANGE constraint

Automaton Figure 5.535 depicts the automaton associated with the LONGEST_CHANGE constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a 0-1 signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $\mathtt{VAR}_i$ CTR $\mathtt{VAR}_{i+1} \Leftrightarrow S_i$.

5.239 LONGEST_DECREASING_SEQUENCE

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin constraint on sequences

Constraint LONGEST_DECREASING_SEQUENCE(L, VARIABLES)

Synonym SIZE_LONGEST_DECREASING_SEQUENCE.

Arguments

L	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

L ≥ 0
L $<$range(VARIABLES.var)
required(VARIABLES, var)

Purpose

L is the largest difference between the first and the last value of the maximum decreasing sequences of the collection VARIABLES.

A sequence of consecutive variables $X_i, X_{i+1}, \ldots, X_j$ ($1 \leq i \leq j \leq |$VARIABLES$|$) of the collection of variables VARIABLES is a *maximum decreasing sequence* if all the following conditions simultaneously apply:

- $X_i \geq X_{i+1} \geq \cdots \geq X_j$,
- $i = 1$ or $X_{i-1} < X_i$,
- $i = |$VARIABLES$|$ or $X_j < X_{j+1}$.

Example

$(0, \langle 0, 1, 2, 5\rangle)$
$(0, \langle 8, 8\rangle)$
$(6, \langle 10, 8, 8, 6, 4, 9, 10, 8\rangle)$

Figure 5.537 gives a graphical representation of the third example of the **Example** slot with its two maximum decreasing sequences in red of respective size 6 and 2. The corresponding LONGEST_DECREASING_SEQUENCE constraint holds since its first argument L is fixed to the maximum size 6.

Typical

L > 0
$|$VARIABLES$| > 1$
nval(VARIABLES.var) > 2

Typical model nval(VARIABLES.var) > 2

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: L determined by VARIABLES.

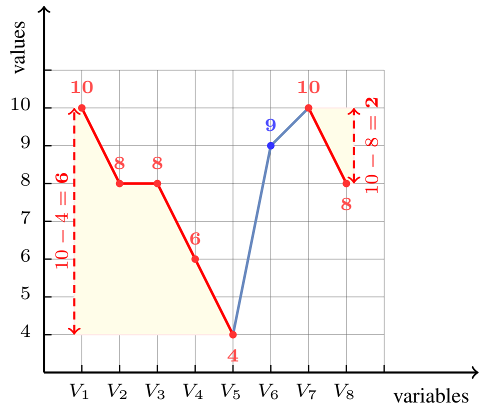

Figure 5.537: Illustration of the third example of the **Example** slot: a sequence of eight variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8 respectively fixed to values 10, 8, 8, 6, 4, 9, 10, 8 and its two maximum decreasing sequences in red of respective size $10-4=6$ and $10-8=2$.

5.240 LONGEST_INCREASING_SEQUENCE

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin constraint on sequences

Constraint LONGEST_INCREASING_SEQUENCE(L, VARIABLES)

Synonym SIZE_LONGEST_INCREASING_SEQUENCE.

Arguments

L	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

L ≥ 0
L $<$range(VARIABLES.var)
required(VARIABLES, var)

Purpose

L is the largest difference between the first and the last value of the maximum increasing sequences of the collection VARIABLES.
A sequence of consecutive variables $X_i, X_{i+1}, \ldots, X_j$ ($1 \leq i \leq j \leq |\text{VARIABLES}|$) of the collection of variables VARIABLES is a *maximum increasing sequence* if all the following conditions simultaneously apply:

- $X_i \leq X_{i+1} \leq \cdots \leq X_j$,
- $i = 1$ or $X_{i-1} > X_i$,
- $i = |\text{VARIABLES}|$ or $X_j > X_{j+1}$.

Example

$(7, \langle 10, 8, 8, 6, 4, 9, 11, 8 \rangle)$
$(0, \langle 10, 8, 7, 5, 4, 3, 1, 0 \rangle)$

Figure 5.540 gives a graphical representation of the first example of the **Example** slot with its two maximum increasing sequences in red of respective size 0 and 7. The corresponding LONGEST_INCREASING_SEQUENCE constraint holds since its first argument L is fixed to the maximum size 7.

Typical

L > 0
$|\text{VARIABLES}| > 1$
nval(VARIABLES.var) > 2

Typical model nval(VARIABLES.var) > 2

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: L determined by VARIABLES.

5.241 LT

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic.

Constraint LT(VAR1, VAR2)

Synonyms REL, XLTY.

Arguments

```
VAR1 : dvar
VAR2 : dvar
```

Purpose Enforce the fact that the first variable is strictly less than the second variable.

Example $(1, 8)$

The LT constraint holds since 1 is strictly less than 8.

Symmetries

- VAR1 can be replaced by any value $<$ VAR2.
- VAR2 can be replaced by any value $>$ VAR1.

Systems LT in **Choco**, REL in **Gecode**, XLTY in **JaCoP**, #< in **SICStus**.

See also **common keyword:** EQ *(binary constraint,arithmetic constraint)*.

implies: LEQ, NEQ.

implies (if swap arguments): GT.

negation: GEQ.

Keywords **constraint arguments:** binary constraint.

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

5.242 MAP

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Inspired by [387]

Constraint MAP(NBCYCLE, NBTREE, NODES)

Arguments

```
NBCYCLE : dvar
NBTREE  : dvar
NODES   : collection(index-int, succ-dvar)
```

Restrictions

NBCYCLE ≥ 0
NBTREE ≥ 0
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ $\leq$ |NODES|

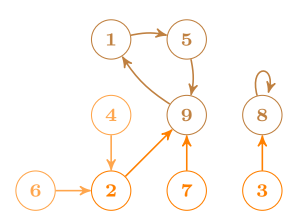
Purpose

Number of trees and number of cycles of a map. We take the description of a map from [387, page 459]:

> *"Every map decomposes into a set of connected components, also called connected maps. Each component consists of the set of all points that wind up on the same cycle, with each point on the cycle attached to a tree of all points that enter the cycle at that point."*

Example

$$\left(\begin{array}{l} 2,3,\left\langle\begin{array}{ll} \text{index}-1 & \text{succ}-5, \\ \text{index}-2 & \text{succ}-9, \\ \text{index}-3 & \text{succ}-8, \\ \text{index}-4 & \text{succ}-2, \\ \text{index}-5 & \text{succ}-9, \\ \text{index}-6 & \text{succ}-2, \\ \text{index}-7 & \text{succ}-9, \\ \text{index}-8 & \text{succ}-8, \\ \text{index}-9 & \text{succ}-1 \end{array}\right\rangle \end{array}\right)$$



The MAP constraint holds since, as shown by part (B) of Figure 5.543, the graph corresponding to the NODES collection is a map containing NBCYCLE $=2$ cycles (i.e., a first cycle involving vertices 1, 5 and 9 and a second cycle involving vertex 8) and 3 trees (i.e., two trees respectively involving vertices 7 and 4, 6, 2 and attached to the first cycle, and one tree mentioning vertex 3 linked to the second cycle.)

Typical

$\mathtt{NBCYCLE} > 0$
$\mathtt{NBTREE} > 0$
$\mathtt{NBCYCLE} < |\mathtt{NODES}|$
$\mathtt{NBCYCLE} < \mathtt{NBTREE}$
$|\mathtt{NODES}| > 2$

Symmetry

Items of NODES are permutable.

Arg. properties

- Functional dependency: NBCYCLE determined by NODES.
- Functional dependency: NBTREE determined by NODES.

See also

common keyword: CYCLE, GRAPH_CROSSING, TREE *(graph partitioning constraint)*.

Keywords

constraint arguments: pure functional dependency.

constraint type: graph constraint, graph partitioning constraint.

filtering: DFS-bottleneck.

final graph structure: connected component.

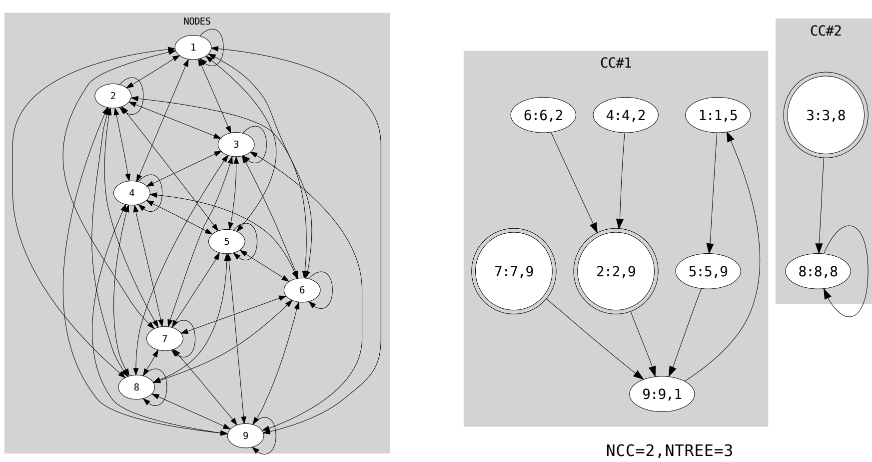
modelling: functional dependency.

Arc input(s)	NODES
Arc generator	*CLIQUE* $\mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	nodes1.succ = nodes2.index
Graph property(ies)	• **NCC**= NBCYCLE • **NTREE**= NBTREE

Graph model Note that, for the argument NBTREE of the MAP constraint, we consider a definition different from the one used for the argument NTREES of the TREE constraint:

- In the MAP constraint the number of trees NBTREE is equal to the number of vertices of the final graph, which both do not belong to any circuit and have a successor that is located on a circuit. Therefore we count three trees in the context of the **Example** slot.
- In the TREE constraint the number of trees NTREES is equal to the number of connected components of the final graph.

Parts (A) and (B) of Figure 5.543 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NCC** graph property, we display the two connected components of the final graph. Each of them corresponds to a connected map. The first connected map is made up from one circuit and two trees, while the second one consists of one circuit and one tree. Since we also use the **NTREE** graph property, we display with a double circle those vertices that do not belong to any circuit but for which at least one successor belongs to a circuit.



(A) **(B)**

Figure 5.543: Initial and final graph of the MAP constraint

5.243 MAX_DECREASING_SLOPE

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin
Motivated by time series.

Constraint
MAX_DECREASING_SLOPE(MAX, VARIABLES)

Arguments

MAX	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

MAX ≥ 0
MAX $<$range(VARIABLES.var)
required(VARIABLES, var)
$|$VARIABLES$| > 0$

Purpose

Given a sequence of variables VARIABLES $= V_1, V_2, \ldots, V_n$, sets MAX to 0 if $\nexists i \in [1, n-1] | V_i > V_{i+1}$, otherwise sets MAX to $\max_{i \in [1,n-1] | V_i > V_{i+1}} (V_i - V_{i+1})$.

Example

$(4, \langle 1, 1, 5, 8, 6, 2, 4, 1, 2 \rangle)$
$(0, \langle 1, 3, 5, 8 \rangle)$
$(8, \langle 3, 1, 9, 1 \rangle)$

The first MAX_DECREASING_SLOPE constraint holds since the sequence 1 1 5 8 6 2 4 1 2 contains two decreasing subsequences 8 6 2 and 4 1 and the maximum slope is equal to $\max(8-6, 6-2, 4-1) = 4$ as shown on Figure 5.544.

Typical

MAX > 0
MAX $<$range(VARIABLES.var) $- 1$
$|$VARIABLES$| > 2$
range(VARIABLES.var) > 2

Typical model
nval(VARIABLES.var) > 2

Symmetry
One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties
Functional dependency: MAX determined by VARIABLES.

Usage
Getting the maximum slope over the decreasing sequences of time series.

Counting

5.244 MAX_INCREASING_SLOPE

DESCRIPTION LINKS AUTOMATON

Origin Motivated by time series.

Constraint MAX_INCREASING_SLOPE(MAX, VARIABLES)

Arguments

MAX : dvar
VARIABLES : collection(var−dvar)

Restrictions

MAX ≥ 0
MAX $<$range(VARIABLES.var)
required(VARIABLES, var)
$|$VARIABLES$| > 0$

Purpose Given a sequence of variables VARIABLES $= V_1, V_2, \ldots, V_n$, sets MAX to 0 if $\nexists i \in [1, n-1] | V_i < V_{i+1}$, otherwise sets MAX to $\max_{i \in [1,n-1] | V_i < V_{i+1}} (V_{i+1} - V_i)$.

Example

$(4, \langle 1, 1, 5, 8, 6, 2, 2, 1, 2 \rangle)$
$(0, \langle 9, 8, 6, 4, 1, 0 \rangle)$
$(8, \langle 9, 6, 6, 4, 1, 9 \rangle)$

The first MAX_INCREASING_SLOPE constraint holds since the sequence 1 1 5 8 6 2 2 1 2 contains two increasing subsequences 1 5 8 and 1 2 and the maximum slope is equal to $\max(5-1, 8-5, 2-1) = 4$ as shown on Figure 5.546.

Typical

MAX > 0
MAX $<$range(VARIABLES.var) $- 1$
$|$VARIABLES$| > 2$
range(VARIABLES.var) > 2

Typical model nval(VARIABLES.var) > 2

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

5.245 MAX_INDEX

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint MAX_INDEX(MAX_INDEX, VARIABLES)

Arguments

MAX_INDEX : dvar
VARIABLES : collection(index−int, var−dvar)

Restrictions

$|$VARIABLES$| > 0$
MAX_INDEX ≥ 0
MAX_INDEX $\leq |$VARIABLES$|$
required(VARIABLES, [index, var])
VARIABLES.index ≥ 1
VARIABLES.index $\leq |$VARIABLES$|$
distinct(VARIABLES, index)

Purpose MAX_INDEX is one of the indices of the collection of variables VARIABLES corresponding to its maximum value.

Example

$$\left(3, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{var}-3, \\ \texttt{index}-2 & \texttt{var}-2, \\ \texttt{index}-3 & \texttt{var}-7, \\ \texttt{index}-4 & \texttt{var}-2, \\ \texttt{index}-5 & \texttt{var}-7 \end{array} \right\rangle \right)$$

The attribute var $=$ 7 of the third and fifth items of the collection VARIABLES is the maximum value over values $3, 2, 7, 2, 7$. Consequently, the MAX_INDEX constraint holds since its first argument MAX_INDEX is set to $3 \in \{3, 5\}$.

Typical

$|$VARIABLES$| > 0$
range(VARIABLES.var) > 1

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

See also **comparison swapped:** MIN_INDEX.

Keywords

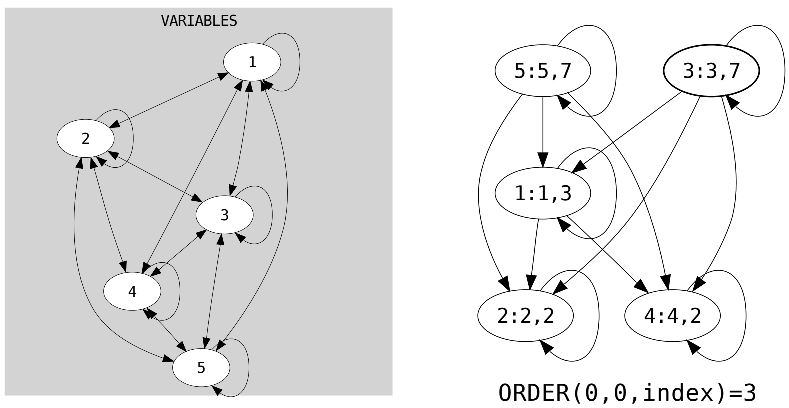
characteristic of a constraint: maximum.

constraint type: order constraint.

modelling: functional dependency.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	$\bigvee\left(\begin{array}{l}\texttt{variables1.key} = \texttt{variables2.key},\\ \texttt{variables1.var} > \texttt{variables2.var}\end{array}\right)$
Graph property(ies)	**ORDER**(0, 0, index) = MAX_INDEX

Graph model Parts (A) and (B) of Figure 5.548 respectively show the initial and final graph associated with the **Example** slot. Since we use the **ORDER** graph property, the vertex of rank 0 (without considering the loops) of the final graph is outlined with a thick circle.



(A) **(B)**

Figure 5.548: Initial and final graph of the MAX_INDEX constraint

5.246 MAX_N

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [29]

Constraint MAX_N(MAX, RANK, VARIABLES)

Arguments

MAX	:	dvar
RANK	:	int
VARIABLES	:	collection(var−dvar)

Restrictions

RANK ≥ 0
RANK $<$ |VARIABLES|
|VARIABLES| > 0
required(VARIABLES, var)

Purpose

MAX is the maximum value of rank RANK (i.e., the RANKth largest distinct value, identical values are merged) of the collection of domain variables VARIABLES. The maximum value has rank 0.

Example

$(6, 1, \langle 3, 1, 7, 1, 6\rangle)$

The MAX_N constraint holds since its first argument MAX $= 6$ is fixed to the second (i.e., RANK $+ 1$) largest distinct value of the collection $\langle 3, 1, 7, 1, 6\rangle$.

Typical

RANK > 0
RANK < 3
|VARIABLES| > 1
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to MAX as well as to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: MAX determined by RANK and VARIABLES.

Algorithm [29].

Reformulation The constraint AMONG_VAR(1, ⟨MAX⟩, VARIABLES) enforces MAX to be assigned one of the values of VARIABLES. The constraint NVALUE(NVAL, VARIABLES) provides a hand on the number of distinct values assigned to the variables of VARIABLES. By associating to each variable V_i ($i \in [1, |\text{VARIABLES}|]$) of the VARIABLES collection a *rank* variable $R_i \in$

$[0, |\texttt{VARIABLES}| - 1]$ with the reified constraint $R_i = \texttt{RANK} \Leftrightarrow V_i = \texttt{MAX}$, the inequality $R_i < \texttt{NVAL}$, and by creating for each pair of variables V_i, V_j $(i, j < i \in [1, |\texttt{VARIABLES}|])$ the reified constraints

$V_i > V_j \Leftrightarrow R_i < R_j$,
$V_i = V_j \Leftrightarrow R_i = R_j$,
$V_i < V_j \Leftrightarrow R_i > R_j$,

one can reformulate the MAX_N constraint in term of $3 \cdot \frac{|\texttt{VARIABLES}| \cdot (|\texttt{VARIABLES}| - 1)}{2} + 1$ reified constraints.

See also

comparison swapped: MIN_N.

generalisation: MAXIMUM *(absolute maximum replaced by maximum or order* n*)*.

Keywords

5.247 MAX_NVALUE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Derived from NVALUE.

Constraint MAX_NVALUE(MAX, VARIABLES)

Arguments

MAX : dvar
VARIABLES : collection(var−dvar)

Restrictions

MAX $\geq$ 1
MAX $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose MAX is the maximum number of times that the same value is taken by the variables of the collection VARIABLES.

Example

$(3, \langle 9, 1, 7, 1, 1, 6, 7, 7, 4, 9\rangle)$
$(1, \langle 9, 1, 7, 3, 2, 6\rangle)$
$(6, \langle 5, 5, 5, 5, 5, 5\rangle)$

In the first example, values $1, 4, 6, 7, 9$ are respectively used $3, 1, 1, 3, 2$ times. So the maximum number of time MAX that a same value occurs is 3. Consequently the corresponding MAX_NVALUE constraint holds.

Typical

MAX $>$ 1
MAX $<$ |VARIABLES|
|VARIABLES| $>$ 1
range(VARIABLES.var) $>$ 1

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Functional dependency: MAX determined by VARIABLES.

Usage This constraint may be used in order to replace a set of COUNT or AMONG constraints were one would have to generate explicitly one constraint for each potential value. Also useful for constraining the number of occurrences of the mostly used value without knowing this value in advance and without giving explicitly an upper limit on the number of occurrences of each value as it is done in the GLOBAL_CARDINALITY constraint.

Reformulation Assume that VARIABLES is not empty. Let α and β respectively denote the smallest and largest possible values that can be assigned to the variables of the VARIABLES collection. Let the variables $O_\alpha, O_{\alpha+1}, \ldots, O_\beta$ respectively correspond to the number of occurrences of values $\alpha, \alpha+1, \ldots, \beta$ within the variables of the VARIABLES collection. The

MAX_NVALUE constraint can be expressed as the conjunction of the following two constraints:

GLOBAL_CARDINALITY $(\texttt{VARIABLES},$
$\langle \texttt{val} - \alpha\ \texttt{noccurrence} - O_\alpha,$
$\texttt{val} - \alpha + 1\ \texttt{noccurrence} - O_{\alpha+1},$
$\ldots$
$\texttt{val} - \beta\ \texttt{noccurrence} - O_\beta\rangle),$

MAXIMUM$(\texttt{MAX}, \langle O_\alpha, O_{\alpha+1}, \ldots, O_\beta\rangle).$

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**MAX_NSCC** = MAX

Graph model Because of the arc constraint, each strongly connected component of the final graph corresponds to a distinct value that is assigned to a subset of variables of the VARIABLES collection. Therefore the number of vertices of the largest strongly connected component is equal to the mostly used value.

Parts (A) and (B) of Figure 5.550 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **MAX_NSCC** graph property, we show the largest strongly connected component of the final graph.

5.248 MAX_OCC_OF_CONSECUTIVE_TUPLES_OF_VALUES

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Design.

Constraint MAX_OCC_OF_CONSECUTIVE_TUPLES_OF_VALUES(MAX, K, VECTORS)

Type

VECTOR : collection(var−dvar)

Arguments

MAX : int
K : int
VECTORS : collection(vec − VECTOR)

Restrictions

required(VECTOR, var)
$|\texttt{VECTOR}| \geq 2$
ALLDIFFERENT(VECTOR)
$\texttt{MAX} \geq 1$
$\texttt{K} \geq 2$
$\texttt{K} < |\texttt{VECTOR}|$
required(VECTORS, vec)
$|\texttt{VECTORS}| \geq 1$
same_size(VECTORS, vec)

Purpose

MAX is equal to the maximum number of occurrences of identical vectors derived from the vectors VECTORS in the following way. To each vector $\langle v_1, v_2, \ldots, v_m\rangle$ of VECTORS (with $v_1, v_2, \ldots, v_m$ distinct) we generate all vectors $\langle u_1, u_2, \ldots, u_{\texttt{K}}\rangle$ such that $u_1 = v_p$, $u_2 = v_{p+1}, \ldots, u_{\texttt{K}} = v_{p+\texttt{K}-1}$ or $u_1 = v_{p+\texttt{K}-1}$, $u_2 = v_{p+\texttt{K}-2}, \ldots, u_{\texttt{K}} = v_p$ (with $1 \leq p \leq m - \texttt{K} + 1$).

Example

$(1, 2, \langle \texttt{vec} - \langle 4, 1, 3\rangle, \texttt{vec} - \langle 2, 7, 6\rangle, \texttt{vec} - \langle 5, 9, 8\rangle\rangle)$

Given the three vectors of the example we respectively generate:

- the pairs $\langle 4, 1\rangle$, $\langle 1, 4\rangle$, $\langle 1, 3\rangle$, $\langle 3, 1\rangle$ from the triple $\langle 4, 1, 3\rangle$,
- the pairs $\langle 2, 7\rangle$, $\langle 7, 2\rangle$, $\langle 7, 6\rangle$, $\langle 6, 7\rangle$ from the triple $\langle 2, 7, 6\rangle$,
- the pairs $\langle 5, 9\rangle$, $\langle 9, 5\rangle$, $\langle 9, 8\rangle$, $\langle 8, 9\rangle$ from the triple $\langle 5, 9, 8\rangle$.

Putting these pairs together, we get the set of pairs $\{\langle 1, 3\rangle, \langle 1, 4\rangle, \langle 2, 7\rangle, \langle 3, 1\rangle, \langle 4, 1\rangle, \langle 5, 9\rangle, \langle 6, 7\rangle, \langle 7, 2\rangle, \langle 7, 6\rangle, \langle 8, 9\rangle, \langle 9, 5\rangle, \langle 9, 8\rangle\}$. The MAX_OCC_OF_CONSECUTIVE_TUPLES_OF_VALUES constraint holds since the components of each of the original three vectors are distinct, and since MAX is set to one and all the generated pairs are distinct.

Typical

$\texttt{MAX} = 1$
$\texttt{K} = 2$
$|\texttt{VECTORS}| > 2$

Arg. properties

- Functional dependency: MAX determined by K and VECTORS.
- Contractible wrt. VECTORS when $\texttt{MAX} = 1$.

Usage

This constraint occurs in balanced block design problems [374].

See also

modelling: functional dependency.

5.249 MAX_OCC_OF_SORTED_TUPLES_OF_VALUES

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Design.

Constraint MAX_OCC_OF_SORTED_TUPLES_OF_VALUES(MAX, K, VECTORS)

Type VECTOR : collection(var−dvar)

Arguments

MAX : int
K : int
VECTORS : collection(vec − VECTOR)

Restrictions

required(VECTOR, var)
$|\text{VECTOR}| \geq 2$
ALLDIFFERENT(VECTOR)
$\text{MAX} \geq 1$
$\text{K} \geq 2$
$\text{K} < |\text{VECTOR}|$
required(VECTORS, vec)
$|\text{VECTORS}| \geq 1$
same_size(VECTORS, vec)

Purpose MAX is equal to the maximum number of occurrences of identical vectors derived from the vectors VECTORS in the following way. To each vector $\langle v_1, v_2, \ldots, v_m\rangle$ of VECTORS (with $v_1, v_2, \ldots, v_m$ distinct) let $\langle s_1, s_2, \ldots, s_m\rangle$ be the corresponding sorted vector by increasing component. We generate all vectors $\langle u_1, u_2, \ldots, u_K\rangle$ such that $u_1 = s_{i_1}$, $u_2 = s_{i_2}, \ldots, u_K = s_{i_K}$ (with $1 \leq i_1 < i_2 < \cdots < i_K \leq m$).

Example

$$\left(1, 2, \left\langle \begin{array}{l} \text{vec} - \langle 4,2,1\rangle, \\ \text{vec} - \langle 2,3,5\rangle, \\ \text{vec} - \langle 3,6,4\rangle, \\ \text{vec} - \langle 5,4,7\rangle, \\ \text{vec} - \langle 6,5,1\rangle, \\ \text{vec} - \langle 7,6,2\rangle, \\ \text{vec} - \langle 3,1,7\rangle \end{array} \right\rangle \right)$$

Given the seven vectors of the example we respectively generate:

- the pairs $\langle 1,2\rangle$, $\langle 1,4\rangle$ and $\langle 2,4\rangle$ from the triple $\langle 4,2,1\rangle$,
- the pairs $\langle 2,3\rangle$, $\langle 2,5\rangle$ and $\langle 3,5\rangle$ from the triple $\langle 2,3,5\rangle$,
- the pairs $\langle 3,4\rangle$, $\langle 3,6\rangle$ and $\langle 4,6\rangle$ from the triple $\langle 3,6,4\rangle$,
- the pairs $\langle 4,5\rangle$, $\langle 4,7\rangle$ and $\langle 5,7\rangle$ from the triple $\langle 5,4,7\rangle$,
- the pairs $\langle 1,5\rangle$, $\langle 1,6\rangle$ and $\langle 5,6\rangle$ from the triple $\langle 6,5,1\rangle$,

- the pairs $\langle 2,6\rangle$, $\langle 2,7\rangle$ and $\langle 6,7\rangle$ from the triple $\langle 7,6,2\rangle$,
- the pairs $\langle 1,3\rangle$, $\langle 1,7\rangle$ and $\langle 3,7\rangle$ from the triple $\langle 3,1,7\rangle$.

Putting these pairs together, we get the set of pairs $\{\langle 1,2\rangle$, $\langle 1,3\rangle$, $\langle 1,4\rangle$, $\langle 1,5\rangle$, $\langle 1,6\rangle$, $\langle 1,7\rangle$, $\langle 2,3\rangle$, $\langle 2,4\rangle$, $\langle 2,5\rangle$, $\langle 2,6\rangle$, $\langle 2,7\rangle$, $\langle 3,4\rangle$, $\langle 3,5\rangle$, $\langle 3,6\rangle$, $\langle 3,7\rangle$, $\langle 4,5\rangle$, $\langle 4,6\rangle$, $\langle 4,7\rangle$, $\langle 5,6\rangle$, $\langle 5,7\rangle$, $\langle 6,7\rangle\}$. The MAX_OCC_OF_SORTED_TUPLES_OF_VALUES constraint holds since each vector has pairwise distinct components, and since MAX is set to one and all the generated pairs are distinct.

Typical

$\texttt{MAX} = 1$
$\texttt{K} + 1 = |\texttt{VECTOR}|$
$|\texttt{VECTORS}| > 2$

Arg. properties

- Functional dependency: MAX determined by K and VECTORS.
- Contractible wrt. VECTORS when $\texttt{MAX} = 1$.

Usage

This constraint occurs in balanced block design problems where all vectors are not necessarily sorted.

See also

5.250 MAX_OCC_OF_TUPLES_OF_VALUES

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Design.

Constraint MAX_OCC_OF_TUPLES_OF_VALUES(MAX, K, VECTORS)

Type VECTOR : collection(var−dvar)

Arguments

MAX : int
K : int
VECTORS : collection(vec − VECTOR)

Restrictions

required(VECTOR, var)
$|\mathtt{VECTOR}| \geq 2$
STRICTLY_INCREASING(VECTOR)
$\mathtt{MAX} \geq 1$
$\mathtt{K} \geq 2$
$\mathtt{K} < |\mathtt{VECTOR}|$
required(VECTORS, vec)
$|\mathtt{VECTORS}| \geq 1$
same_size(VECTORS, vec)

Purpose

MAX is equal to the maximum number of occurrences of identical vectors derived from the vectors VECTORS in the following way. To each vector $\langle v_1, v_2, \ldots, v_m\rangle$ (with $v_1 < v_2 \wedge \cdots \wedge v_{m-1} < v_m$) of VECTORS we generate all vectors $\langle u_1, u_2, \ldots, u_{\mathtt{K}}\rangle$ such that $u_1 = v_{i_1}, u_2 = v_{i_2}, \ldots, u_{\mathtt{K}} = v_{i_{\mathtt{K}}}$ (with $1 \leq i_1 < i_2 < \cdots < i_{\mathtt{K}} \leq m$).

Example

$$\left(1, 2, \left\langle \begin{array}{l} \mathtt{vec} - \langle 1,2,4\rangle, \\ \mathtt{vec} - \langle 2,3,5\rangle, \\ \mathtt{vec} - \langle 3,4,6\rangle, \\ \mathtt{vec} - \langle 4,5,7\rangle, \\ \mathtt{vec} - \langle 1,5,6\rangle, \\ \mathtt{vec} - \langle 2,6,7\rangle, \\ \mathtt{vec} - \langle 1,3,7\rangle \end{array} \right\rangle\right)$$

Given the seven vectors of the example we respectively generate:

- the pairs $\langle 1,2\rangle$, $\langle 1,4\rangle$ and $\langle 2,4\rangle$ from the triple $\langle 1,2,4\rangle$,
- the pairs $\langle 2,3\rangle$, $\langle 2,5\rangle$ and $\langle 3,5\rangle$ from the triple $\langle 2,3,5\rangle$,
- the pairs $\langle 3,4\rangle$, $\langle 3,6\rangle$ and $\langle 4,6\rangle$ from the triple $\langle 3,4,6\rangle$,
- the pairs $\langle 4,5\rangle$, $\langle 4,7\rangle$ and $\langle 5,7\rangle$ from the triple $\langle 4,5,7\rangle$,
- the pairs $\langle 1,5\rangle$, $\langle 1,6\rangle$ and $\langle 5,6\rangle$ from the triple $\langle 1,5,6\rangle$,
- the pairs $\langle 2,6\rangle$, $\langle 2,7\rangle$ and $\langle 6,7\rangle$ from the triple $\langle 2,6,7\rangle$,

- the pairs $\langle 1,3\rangle$, $\langle 1,7\rangle$ and $\langle 3,7\rangle$ from the triple $\langle 1,3,7\rangle$.

Putting these pairs together, we get the set of pairs $\{\langle 1,2\rangle$, $\langle 1,3\rangle$, $\langle 1,4\rangle$, $\langle 1,5\rangle$, $\langle 1,6\rangle$, $\langle 1,7\rangle$, $\langle 2,3\rangle$, $\langle 2,4\rangle$, $\langle 2,5\rangle$, $\langle 2,6\rangle$, $\langle 2,7\rangle$, $\langle 3,4\rangle$, $\langle 3,5\rangle$, $\langle 3,6\rangle$, $\langle 3,7\rangle$, $\langle 4,5\rangle$, $\langle 4,6\rangle$, $\langle 4,7\rangle$, $\langle 5,6\rangle$, $\langle 5,7\rangle$, $\langle 6,7\rangle\}$. The MAX_OCC_OF_TUPLES_OF_VALUES constraint holds since the components of the original seven vectors are strictly increasing, and since MAX is set to one and all the generated pairs are distinct.

Typical

$\mathtt{MAX} \leq 2$
$|\mathtt{VECTOR}| < \mathtt{K} + 5$
$\mathtt{K} = 2 \vee \mathtt{K} + 1 = |\mathtt{VECTOR}|$
$|\mathtt{VECTORS}| > 2$

Arg. properties

- Functional dependency: MAX determined by K and VECTORS.
- Contractible wrt. VECTORS when $\mathtt{MAX} = 1$.

Usage

This constraint occurs in balanced block design problems [218, 273] such as Steiner or Kirkman triples.

5.251 MAX_SIZE_SET_OF_CONSECUTIVE_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint MAX_SIZE_SET_OF_CONSECUTIVE_VAR(MAX, VARIABLES)

Arguments

MAX	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

MAX ≥ 1
MAX $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose MAX is the size of the largest set of variables of the collection VARIABLES that all take their values in a set of consecutive values.

Example

(6, ⟨3, 1, 3, 7, 4, 1, 2, 8, 7, 6⟩)
(2, ⟨2, 6, 7, 3, 0, 9⟩)

In the first example, the two sets $\{3, 1, 3, 4, 1, 2\}$ and $\{7, 8, 7, 6\}$ take respectively their values in the two following sets of consecutive values $\{1, 2, 3, 4\}$ and $\{6, 7, 8\}$. Consequently, the corresponding MAX_SIZE_SET_OF_CONSECUTIVE_VAR constraint holds since the cardinality of the largest set of variables is 6.

Typical

MAX < |VARIABLES|
|VARIABLES| > 0
range(VARIABLES.var) > 1

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: MAX determined by VARIABLES.

5.252 MAXIMUM

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint MAXIMUM(`MAX`, `VARIABLES`)

Synonym MAX.

Arguments

`MAX`	:	`dvar`
`VARIABLES`	:	`collection(var−dvar)`

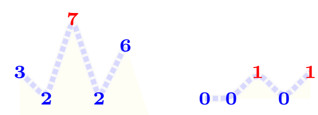
Restrictions

$|$`VARIABLES`$| > 0$
`required(VARIABLES, var)`

Purpose `MAX` is the maximum value of the collection of domain variables `VARIABLES`.

Example

(7, ⟨3, 2, 7, 2, 6⟩)
(1, ⟨0, 0, 1, 0, 1⟩)



The first MAXIMUM constraint holds since its first argument `MAX` = 7 is fixed to the maximum value of the collection ⟨3, 2, 7, 2, 6⟩.

Typical

$|$`VARIABLES`$| > 1$
`range(VARIABLES.var)` > 1

Typical model `nval(VARIABLES.var)` > 2

Symmetries

- Items of `VARIABLES` are permutable.
- All occurrences of two distinct values of `VARIABLES.var` can be swapped.
- One and the same constant can be added to `MAX` as well as to the `var` attribute of all items of `VARIABLES`.

Arg. properties

- Functional dependency: `MAX` determined by `VARIABLES`.
- Aggregate: `MAX(max)`, `VARIABLES(union)`.

Usage In some project scheduling problems one has to introduce dummy activities that correspond, for example, to the completion time of a given set of activities. In this context one can use the MAXIMUM constraint to get the maximum completion time of a set of tasks.

Remark Note that MAXIMUM is a constraint and not just a function that computes the maximum value of a collection of variables: potential values of `MAX` influence the variables of `VARIABLES`, and reciprocally potential values that can be assigned to variables of `VARIABLES` influence `MAX`.

The MAXIMUM constraint is called MAX in **JaCoP** (`http://www.jacop.eu/`).

Algorithm A filtering algorithm for the MAXIMUM constraint is described in [29].

The MAXIMUM constraint is entailed if all the following conditions hold:

1. `MAX` is fixed.
2. At least one variable of `VARIABLES` is assigned value `MAX`.
3. All variables of `VARIABLES` have their maximum values less than or equal to value `MAX`.

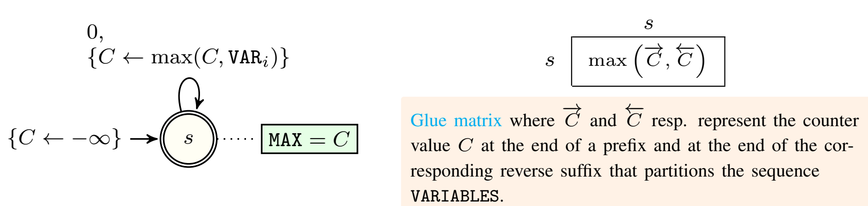

Figure 5.558: Automaton (with one counter) of the MAXIMUM constraint and its glue constraint

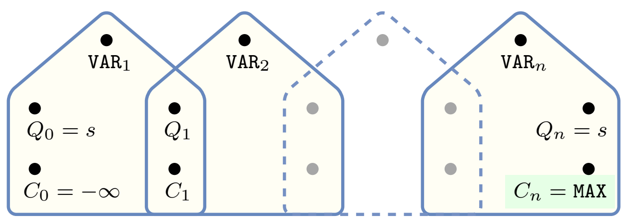

Figure 5.559: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the MAXIMUM constraint: since all states variables $Q_0, Q_1, \ldots, Q_n$ are fixed to the unique state s of the automaton, the transitions constraints share only the counter variable C and the constraint network is Berge-acyclic

5.253 MAXIMUM_MODULO

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin

Derived from MAXIMUM.

Constraint

MAXIMUM_MODULO(MAX, VARIABLES, M)

Arguments

MAX	:	dvar
VARIABLES	:	collection(var−dvar)
M	:	int

Restrictions

$|$VARIABLES$| > 0$
M > 0
required(VARIABLES, var)

Purpose

MAX is a maximum value of the collection of domain variables VARIABLES according to the following partial ordering: $(X \bmod \mathtt{M}) < (Y \bmod \mathtt{M})$.

Example

$(5, \langle 9, 1, 7, 6, 5 \rangle, 3)$

The MAXIMUM_MODULO constraint holds since its first argument MAX is set to value 5, where $5 \bmod 3 = 2$ is greater than or equal to all the expressions $9 \bmod 3 = 0$, $1 \bmod 3 = 1$, $7 \bmod 3 = 1$ and $6 \bmod 3 = 0$.

Typical

M > 1
M $<$maxval(VARIABLES.var)
$|$VARIABLES$| > 1$
range(VARIABLES.var) > 1

Symmetry

Items of VARIABLES are permutable.

Arg. properties

Functional dependency: MAX determined by VARIABLES and M.

See also

comparison swapped: MINIMUM_MODULO.

specialisation: MAXIMUM (variable mod constant *replaced by* variable).

Keywords

characteristic of a constraint: modulo, maximum.

constraint arguments: pure functional dependency.

constraint type: order constraint.

5.254 MEET_SBOXES

▶ ▷ ◁ ◀ DESCRIPTION LINKS LOGIC

Origin Geometry, derived from [349]

Constraint MEET_SBOXES(K, DIMS, OBJECTS, SBOXES)

Synonym MEET.

Types

VARIABLES : collection(v−dvar)
INTEGERS : collection(v−int)
POSITIVES : collection(v−int)

Arguments

K : int
DIMS : sint
OBJECTS : collection(oid−int, sid−dvar, x − VARIABLES)
SBOXES : collection(sid−int, t − INTEGERS, l − POSITIVES)

Restrictions

$|$VARIABLES$| \geq 1$
$|$INTEGERS$| \geq 1$
$|$POSITIVES$| \geq 1$
required(VARIABLES, v)
$|$VARIABLES$| =$ K
required(INTEGERS, v)
$|$INTEGERS$| =$ K
required(POSITIVES, v)
$|$POSITIVES$| =$ K
POSITIVES.v > 0
K > 0
DIMS ≥ 0
DIMS $<$ K
increasing_seq(OBJECTS, [oid])
required(OBJECTS, [oid, sid, x])
OBJECTS.oid ≥ 1
OBJECTS.oid $\leq |$OBJECTS$|$
OBJECTS.sid ≥ 1
OBJECTS.sid $\leq |$SBOXES$|$
$|$SBOXES$| \geq 1$
required(SBOXES, [sid, t, l])
SBOXES.sid ≥ 1
SBOXES.sid $\leq |$SBOXES$|$
do_not_overlap(SBOXES)

Purpose

Holds if, for each pair of objects (O_i, O_j), $i \neq j$, O_i and O_j meet with respect to a set of dimensions depicted by `DIMS`. Each *shape* is defined as a finite set of shifted boxes, where each shifted box is described by a box in a `K`-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a *shifted box* is an entity defined by its shape id `sid`, shift offset `t`, and sizes `l`. Then, a shape is defined as the union of shifted boxes sharing the same shape id. An *object* is an entity defined by its unique object identifier `oid`, shape id `sid` and origin `x`.

Two objects O_i and object O_j *meet* with respect to a set of dimensions depicted by `DIMS` if and only if the two following conditions hold:

- For all shifted box s_i associated with O_i and for all shifted box s_j associated with O_j there exists a dimension $d \in$ `DIMS` such that (1) the start of s_i in dimension d is greater than or equal to the end of s_j in dimension d, or (2) the start of s_j in dimension d is greater than or equal to the end of s_i in dimension d (i.e., there is no overlap between the shifted box of O_i and the shifted box of O_j).
- There exists a shifted box s_i of O_i and there exists a shifted box s_j of O_j such that for all dimensions d (1) the end of s_i in dimension d is greater than or equal to the start of s_j in dimension d, and (2) the end of s_j in dimension d is greater than or equal to the start of s_i in dimension d (i.e., at least two shifted box of O_i and O_j are in contact).

Example

$$\left(\begin{array}{l} 2, \{0,1\}, \\ \left\langle \begin{array}{lll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 3,2\rangle, \\ \texttt{oid}-2 & \texttt{sid}-2 & \texttt{x}-\langle 4,1\rangle, \\ \texttt{oid}-3 & \texttt{sid}-4 & \texttt{x}-\langle 3,4\rangle \end{array} \right\rangle, \\ \left\langle \begin{array}{lll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 1,0\rangle & \texttt{l}-\langle 1,3\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,2\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-3 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 3,1\rangle, \\ \texttt{sid}-3 & \texttt{t}-\langle 0,1\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-3 & \texttt{t}-\langle 2,1\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-4 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,1\rangle \end{array} \right\rangle \end{array}\right)$$

Figure 5.561 shows the objects of the example. Since all the pairs of objects meet the MEET_SBOXES constraint holds.

Typical

$|$`OBJECTS`$| > 1$

Symmetries

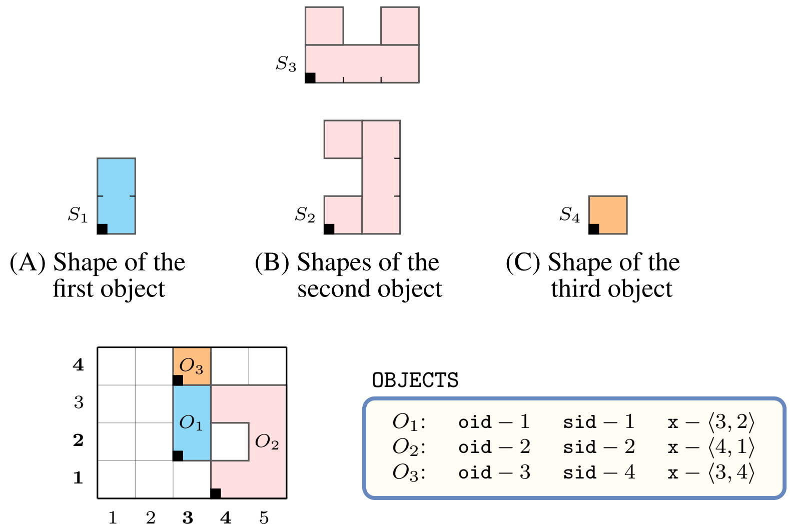
- Items of `OBJECTS` are permutable.
- Items of `SBOXES` are permutable.
- Items of `OBJECTS.x`, `SBOXES.t` and `SBOXES.l` are permutable (*same permutation used*).

Arg. properties

Suffix-contractible wrt. `OBJECTS`.

Remark

One of the eight relations of the *Region Connection Calculus* [349].



(A) Shape of the first object

(B) Shapes of the second object

(C) Shape of the third object

(D) Three objects for which each pair of objects meet

Figure 5.561: (D) the three pairwise meeting objects O_1, O_2, O_3 of the **Example** slot respectively assigned shapes S_1, S_2, S_4; (A), (B), (C) shapes S_1, S_2, S_3 and S_4 are respectively made up from 1, 3, 3 and 1 disjoint shifted box.

5.255 MIN_DECREASING_SLOPE

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Motivated by time series.

Constraint MIN_DECREASING_SLOPE(MIN, VARIABLES)

Arguments

MIN : dvar
VARIABLES : collection(var−dvar)

Restrictions

MIN ≥ 0
MIN $<$range(VARIABLES.var)
required(VARIABLES, var)
$|$VARIABLES$| > 0$

Purpose Given a sequence of variables VARIABLES $= V_1, V_2, \ldots, V_n$, sets MIN to 0 if $\nexists i \in [1, n-1] | V_i > V_{i+1}$, otherwise sets MIN to $\min_{i\in[1,n-1]|V_i>V_{i+1}} (V_i - V_{i+1})$.

Example

$(2, \langle 1, 1, 5, 8, 6, 2, 4, 1, 5\rangle)$
$(0, \langle 1, 1, 1, 3, 4, 7, 7, 7, 9\rangle)$
$(9, \langle 1, 1, 9, 0, 4, 7, 7, 7, 9\rangle)$

The first MIN_DECREASING_SLOPE constraint holds since the sequence 1 1 5 8 6 2 4 1 5 contains two decreasing subsequences 8 6 2 and 4 1 and the minimum slope is equal to $\min(8-6, 6-2, 4-1) = 2$ as shown on Figure 5.562.

Typical

MIN > 1
$|$VARIABLES$| > 2$
range(VARIABLES.var) > 2

Typical model nval(VARIABLES.var) > 2

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: MIN determined by VARIABLES.

Usage Getting the minimum slope over the decreasing sequences of time series.

Counting

5.256 MIN_DIST_BETWEEN_INFLEXION

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Derived from INFLEXION

Constraint MIN_DIST_BETWEEN_INFLEXION(MINDIST, VARIABLES)

Arguments

```
MINDIST   : int
VARIABLES : collection(var-dvar)
```

Restrictions

$\texttt{MINDIST} \geq 0$
$\texttt{MINDIST} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose

Given an integer value MINDIST and a sequence of variables VARIABLES enforce MINDIST to be greater than or equal to the smallest distance between two consecutive inflexions in the sequence VARIABLES, or to |VARIABLES| if no more than one inflexion exists.

An *inflexion* of a sequence of variables VARIABLES is a set of consecutive variables $V_i, V_{i+1}, \ldots, V_{j-1}, V_j$ $(i+1<j)$ such that one of the following conditions holds:

- $V_i < V_{i+1} \wedge V_{i+1} = \cdots = V_{j-1} \wedge V_{j-1} > V_j$,
- $V_i > V_{i+1} \wedge V_{i+1} = \cdots = V_{j-1} \wedge V_{j-1} < V_j$.

In this context, the index j is the *position* of the inflexion (i.e., the first instant when the inflexion is discovered when scanning the sequence of variables VARIABLES from left to right. The *distance between two consecutive inflexions* is the absolute value of the difference of their corresponding positions.

Example

$(2, \langle 2, 2, 3, 3, 2, 2, 1, 4, 4, 3\rangle)$

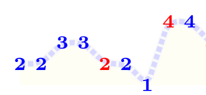

Figure 5.564 shows the three inflexions associated with the sequence 2, 2, 3, 3, 2, 2, 1, 4, 4, 3 and their respective positions 5, 8 and 10 in red. The MIN_DIST_BETWEEN_INFLEXION constraint holds since its first argument MINDIST $=2$ is greater than or equal to the smallest distance 2 between two consecutive inflexions of the sequence of variables VARIABLES.

Typical

$\texttt{MINDIST} > 1$
$|\texttt{VARIABLES}| > 3$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

Typical model

$\texttt{nval}(\texttt{VARIABLES.var}) > 2$

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

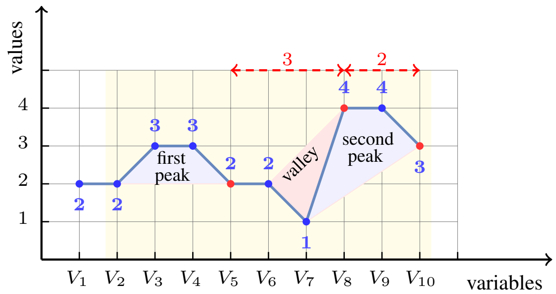

Figure 5.564: Illustration of the **Example** slot: a sequence of ten variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10} respectively fixed to values 2, 2, 3, 3, 2, 2, 1, 4, 4, 3 and its three inflexions, two peaks and one valley; each red point denotes an instant where a new inflexion is discovered while scanning the sequence from left to right; as shown by the rightmost arrow, the minimum distance between two consecutive inflexions is equal to 2.

Solution density for MIN_DIST_BETWEEN_INFLEXION

Solution density for MIN_DIST_BETWEEN_INFLEXION

See also **common keyword:** INFLEXION, LONGEST_DECREASING_SEQUENCE, LONGEST_INCREASING_SEQUENCE, PEAK, VALLEY *(sequence)*.

Keywords

characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint network structure: sliding cyclic(1) constraint network(3).

Automaton Figure 5.565 depicts the automaton associated with the MIN_DIST_BETWEEN_INFLEXION constraint.

STATE SEMANTICS

s	: stationary mode	$(=^*)$
$i0$	: increasing mode (no inflexion yet found)	$(< \{< \mid =\}^*)$
$d0$	: decreasing mode (no inflexion yet found)	$(> \{> \mid =\}^*)$
$i1$	: increasing mode (at least one inflexion already found)	$(< \{< \mid =\}^*)$
$d1$	: decreasing mode (at least one inflexion already found)	$(> \{> \mid =\}^*)$

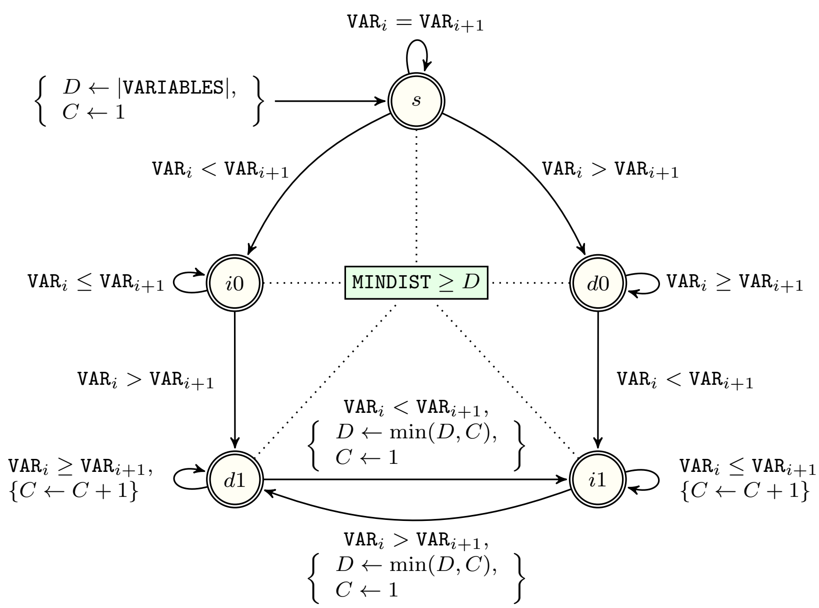

Figure 5.565: Automaton of the MIN_DIST_BETWEEN_INFLEXION constraint (state s means that we are in *stationary* mode, state $i0$ means that we are in *increasing* mode and that we did not yet found any inflexion, state $d0$ means that we are in *decreasing* mode and that we did not yet found any inflexion, state $i1$ means that we are in *increasing* mode and that we already found at least one inflexion, state $d1$ means that we are in *decreasing* mode and that we already found at least one inflexion, the minimum distance between two consecutive inflexions is updated each time we switch from $i1$ to $d1$ mode – or conversely from $d1$ to $i1$ mode – and the counter D is updated accordingly)

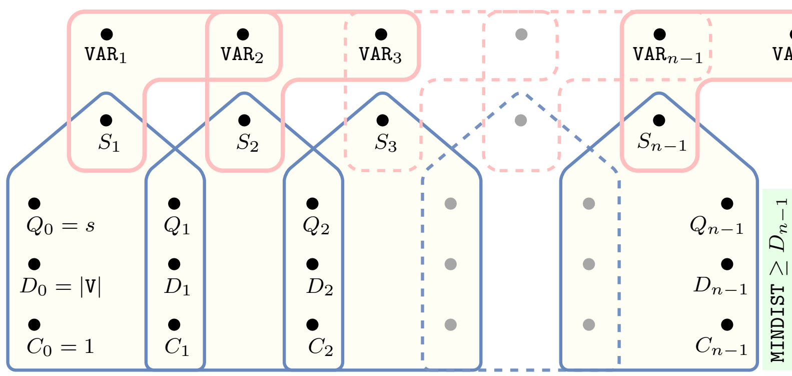

Figure 5.566: Hypergraph of the reformulation corresponding to the automaton of the MIN_DIST_BETWEEN_INFLEXION constraint where V is a shortcut for VARIABLES (since all states of the automaton are accepting there is no restriction on the last variable Q_{n-1})

5.257 MIN_INCREASING_SLOPE

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Motivated by time series.

Constraint MIN_INCREASING_SLOPE(MIN, VARIABLES)

Arguments

MIN : dvar
VARIABLES : collection(var−dvar)

Restrictions

MIN ≥ 0
MIN $<$range(VARIABLES.var)
required(VARIABLES, var)
$|$VARIABLES$| > 0$

Purpose Given a sequence of variables VARIABLES $= V_1, V_2, \ldots, V_n$, sets MIN to 0 if $\nexists i \in [1, n-1] | V_i < V_{i+1}$, otherwise sets MIN to $\min_{i \in [1,n-1] | V_i < V_{i+1}} (V_{i+1} - V_i)$.

Example

$(3, \langle 1, 1, 5, 8, 6, 2, 2, 1, 5 \rangle)$
$(0, \langle 8, 8, 2, 0, 0 \rangle)$
$(9, \langle 1, 1, 0, 9, 6 \rangle)$

The first MIN_INCREASING_SLOPE constraint holds since the sequence 1 1 5 8 6 2 2 1 5 contains two increasing subsequences 1 5 8 and 1 5 and the minimum slope is equal to $\min(5-1, 8-5, 5-1) = 3$ as shown on Figure 5.567.

Typical

MIN > 1
$|$VARIABLES$| > 2$
range(VARIABLES.var) > 2

Typical model nval(VARIABLES.var) > 2

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: MIN determined by VARIABLES.

Usage Getting the minimum slope over the increasing sequences of time series.

Counting

Length (n)	2	3	4	5	6	7	8

Keywords **characteristic of a constraint:** automaton, automaton with counters.
combinatorial object: sequence.
constraint arguments: reverse of a constraint, pure functional dependency.

filtering: glue matrix.

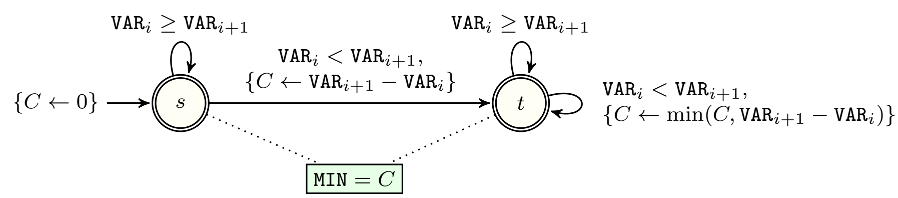
modelling: functional dependency.

Cond. implications

MIN_INCREASING_SLOPE(MIN, VARIABLES)
with range(VARIABLES.var) $=$ MIN $+ 1$
implies MAX_INCREASING_SLOPE(MAX, VARIABLES)
when range(VARIABLES.var) $=$ MAX $+ 1$.

Automaton

Figure 5.568 depicts the automaton associated with the MIN_INCREASING_SLOPE constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $(\mathtt{VAR}_i \geq \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 0) \land (\mathtt{VAR}_i < \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 1)$.



Glue matrix where $\overrightarrow{C}$ and $\overleftarrow{C}$ resp. represent the counter value C at the end of a prefix and at the end of the corresponding reverse suffix that partitions the sequence VARIABLES.

	s	t
s	0	$\overleftarrow{C}$
t	$\overrightarrow{C}$	$\min(\overrightarrow{C}, \overleftarrow{C})$

Figure 5.568: Automaton for the MIN_INCREASING_SLOPE constraint and its glue matrix (note that the reverse of MIN_INCREASING_SLOPE is MIN_DECREASING_SLOPE)

5.258 MIN_INDEX

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint MIN_INDEX(MIN_INDEX, VARIABLES)

Arguments

MIN_INDEX : dvar
VARIABLES : collection(index−int, var−dvar)

Restrictions

$|\texttt{VARIABLES}| > 0$
$\texttt{MIN\_INDEX} \geq 0$
$\texttt{MIN\_INDEX} \leq |\texttt{VARIABLES}|$
required(VARIABLES, [index, var])
$\texttt{VARIABLES.index} \geq 1$
$\texttt{VARIABLES.index} \leq |\texttt{VARIABLES}|$
distinct(VARIABLES, index)

Purpose

MIN_INDEX is one of the indices of the collection of variables VARIABLES corresponding to its minimum value.

Example

$$\left(2, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{var}-3, \\ \texttt{index}-2 & \texttt{var}-2, \\ \texttt{index}-3 & \texttt{var}-7, \\ \texttt{index}-4 & \texttt{var}-2, \\ \texttt{index}-5 & \texttt{var}-6 \end{array} \right\rangle \right)$$
$$\left(4, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{var}-3, \\ \texttt{index}-2 & \texttt{var}-2, \\ \texttt{index}-3 & \texttt{var}-7, \\ \texttt{index}-4 & \texttt{var}-2, \\ \texttt{index}-5 & \texttt{var}-6 \end{array} \right\rangle \right)$$

The attribute var = 2 of the second and fourth items of the collection VARIABLES is the minimum value over values $3, 2, 7, 2, 6$. Consequently, both MIN_INDEX constraints hold since their first arguments MIN_INDEX are respectively set to 2 and 4.

Typical

$|\texttt{VARIABLES}| > 0$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Usage Within the context of scheduling, assume the variables of the VARIABLES collection correspond to the starts of a set of tasks. Then MIN_INDEX gives the indexes of those tasks that can be scheduled first.

See also **comparison swapped:** MAX_INDEX.

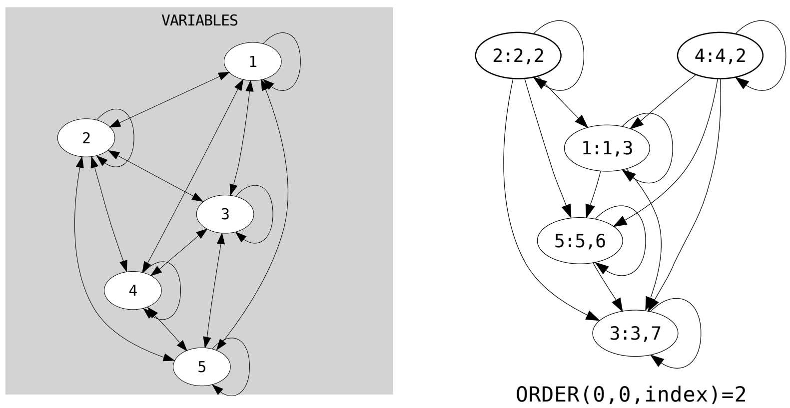
Keywords **characteristic of a constraint:** minimum.

constraint type: order constraint.

modelling: functional dependency.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	$\bigvee\left(\begin{array}{l}\texttt{variables1.key} = \texttt{variables2.key},\\ \texttt{variables1.var} < \texttt{variables2.var}\end{array}\right)$
Graph property(ies)	$\mathbf{ORDER}(0, 0, \texttt{index}) = \texttt{MIN\_INDEX}$

Graph model Parts (A) and (B) of Figure 5.569 respectively show the initial and final graph associated with the two examples of the **Example** slot. Since we use the **ORDER** graph property, the vertices of rank 0 (without considering the loops) of the final graph are outlined with a thick circle.



(A) (B)

Figure 5.569: Initial and final graph of the MIN_INDEX constraint

5.259 MIN_N

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin [29]

Constraint MIN_N(MIN, RANK, VARIABLES)

Arguments

MIN : dvar
RANK : int
VARIABLES : collection(var−dvar)

Restrictions

$|\mathtt{VARIABLES}| > 0$
$\mathtt{RANK} \geq 0$
$\mathtt{RANK} < |\mathtt{VARIABLES}|$
required(VARIABLES, var)

Purpose MIN is the minimum value of rank RANK (i.e., the $\mathtt{RANK}^{th}$ smallest distinct value, identical values are merged) of the collection of domain variables VARIABLES. The minimum value has rank 0.

Example $(3, 1, \langle 3, 1, 7, 1, 6\rangle)$

The MIN_N constraint holds since its first argument $\mathtt{MIN} = 3$ is fixed to the second (i.e., $\mathtt{RANK} + 1$) smallest distinct value of the collection $\langle 3, 1, 7, 1, 6\rangle$. Note that identical values are only counted once: this is why the minimum of order 1 is 3 instead of 1.

Typical

$\mathtt{RANK} > 0$
$\mathtt{RANK} < 3$
$|\mathtt{VARIABLES}| > 1$
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to MIN as well as to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: MIN determined by RANK and VARIABLES.

Algorithm [29].

Reformulation The constraint AMONG_VAR(1, ⟨MIN⟩, VARIABLES) enforces MIN to be assigned one of the values of VARIABLES. The constraint NVALUE(NVAL, VARIABLES) provides a hand on the number of distinct values assigned to the variables of VARIABLES. By associating to each variable V_i ($i \in [1, |\texttt{VARIABLES}|]$) of the VARIABLES collection a *rank* variable $R_i \in [0, |\texttt{VARIABLES}| - 1]$ with the reified constraint $R_i = \texttt{RANK} \Leftrightarrow V_i = \texttt{MIN}$, the inequality $R_i < \texttt{NVAL}$, and by creating for each pair of variables V_i, V_j ($i, j < i \in [1, |\texttt{VARIABLES}|]$) the reified constraints

$V_i < V_j \Leftrightarrow R_i < R_j$,
$V_i = V_j \Leftrightarrow R_i = R_j$,
$V_i > V_j \Leftrightarrow R_i > R_j$,

one can reformulate the MIN_N constraint in term of $3 \cdot \frac{|\texttt{VARIABLES}| \cdot (|\texttt{VARIABLES}| - 1)}{2} + 1$ reified constraints.

See also

comparison swapped: MAX_N.

generalisation: MINIMUM *(absolute minimum replaced by minimum or order* n*)*.

used in reformulation: AMONG_VAR, NVALUE.

Keywords

characteristic of a constraint: rank, minimum, maxint, automaton, automaton with array of counters.

constraint arguments: pure functional dependency.

constraint type: order constraint.

modelling: functional dependency.

Cond. implications

- MIN_N(MIN, RANK, VARIABLES)
  implies ATLEAST(N, VARIABLES, MIN)
  when $\texttt{N} = 1$.
- MIN_N(MIN, RANK, VARIABLES)
  with $\texttt{RANK} = 1$
  and $\texttt{minval}(\texttt{VARIABLES.var}) = 1$
  implies MINIMUM_GREATER_THAN(VAR1, VAR2, VARIABLES).

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	$\bigvee\left(\begin{array}{l}\texttt{variables1.key} = \texttt{variables2.key},\\ \texttt{variables1.var} < \texttt{variables2.var}\end{array}\right)$
Graph property(ies)	**ORDER**(RANK, MAXINT, var) = MIN

Graph model Parts (A) and (B) of Figure 5.570 respectively show the initial and final graph associated with the **Example** slot. Since we use the **ORDER** graph property, the vertex of rank 1 (without considering the loops) of the final graph is shown in grey.

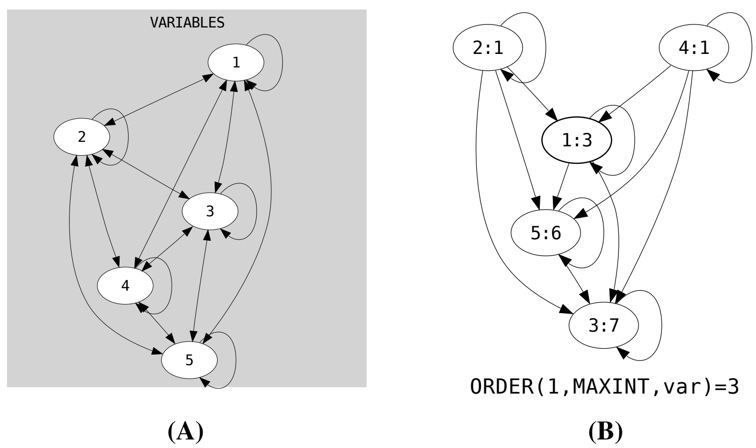


Figure 5.570: Initial and final graph of the MIN_N constraint

Automaton Figure 5.571 depicts the automaton associated with the MIN_N constraint. Figure 5.571 depicts the automaton associated with the MIN_N constraint. To each item of the collection VARIABLES corresponds a signature variable S_i that is equal to 1.

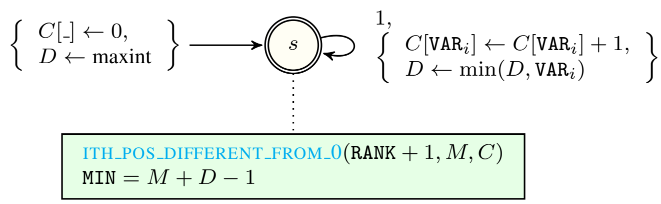

Figure 5.571: Automaton of the MIN_N constraint

5.260 MIN_NVALUE

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin N. Beldiceanu

Constraint MIN_NVALUE(MIN, VARIABLES)

Arguments

MIN : dvar
VARIABLES : collection(var−dvar)

Restrictions

MIN ≥ 1
MIN $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose MIN is the minimum number of times that the same value is taken by the variables of the collection VARIABLES.

Example

$(2, \langle 9, 1, 7, 1, 1, 7, 7, 7, 7, 9\rangle)$
$(5, \langle 8, 8, 8, 8, 8\rangle)$
$(2, \langle 1, 8, 1, 8, 1\rangle)$

In the first example, values $1, 7, 9$ are respectively used $3, 5, 2$ times. So the minimum number of time MIN that a same value occurs is 2. Consequently the corresponding MIN_NVALUE constraint holds.

Typical

$2 *$ MIN $\leq$ |VARIABLES|
|VARIABLES| > 1
range(VARIABLES.var) > 1

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Functional dependency: MIN determined by VARIABLES.

Usage This constraint may be used in order to replace a set of COUNT or AMONG constraints were one would have to generate explicitly one constraint for each potential value. Also useful for constraining the number of occurrences of the less used value without knowing this value in advance and without giving explicitly a lower limit on the number of occurrences of each value as it is done in the GLOBAL_CARDINALITY constraint.

Reformulation Assume that VARIABLES is not empty. Let α and β respectively denote the smallest and largest possible values that can be assigned to the variables of the VARIABLES collection. Let the variables $O_\alpha, O_{\alpha+1}, \ldots, O_\beta$ respectively correspond to the number of occurrences of values $\alpha, \alpha+1, \ldots, \beta$ within the variables of the VARIABLES collection. The

MIN_NVALUE constraint can be expressed as the conjunction of the following two constraints:

GLOBAL_CARDINALITY (VARIABLES,
$\langle$val $-\ \alpha$ noccurrence $-\ O_\alpha$,
val $-\ \alpha+1$ noccurrence $-\ O_{\alpha+1}$,
$\dots$
val $-\ \beta$ noccurrence $-\ O_\beta\rangle$),

MIN_N(MIN, $1, \langle 0, O_\alpha, O_{\alpha+1}, \dots, O_\beta\rangle$).

We use a MIN_N constraint (with its RANK parameter set to 1) instead of a MINIMUM constraint in order to discard the smallest value 0.

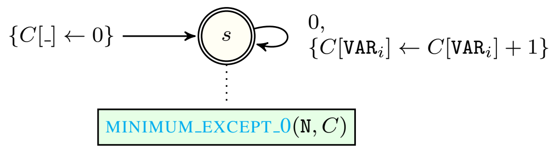

Figure 5.573: Automaton of the MIN_NVALUE constraint

5.261 MIN_SIZE_FULL_ZERO_STRETCH

DESCRIPTION LINKS AUTOMATON

Origin

Derived from the unit commitment problem

Constraint

MIN_SIZE_FULL_ZERO_STRETCH(MINSIZE, VARIABLES)

Arguments

MINSIZE : int
VARIABLES : collection(var−dvar)

Restrictions

MINSIZE ≥ 0
MINSIZE $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose

Given an integer MINSIZE and a sequence of variables VARIABLES enforce MINSIZE to be greater than or equal to the size of the smallest full stretch of zero of VARIABLES or to |VARIABLES| if no full stretch of zero exists.

A *stretch of zero* is a maximum sequence of zero, while a *full stretch of zero* is a stretch of zero that is neither located at the leftmost nor at the rightmost border of the sequence of variables VARIABLES. The *size of a stretch of zero* is the number of zero of the stretch.

Example

$(2, \langle 0, 2, 0, 0, 0, 2, 1, 0, 0, 3\rangle)$

Figure 5.574 shows the smallest full stretch of zero associated with the example. The MIN_SIZE_FULL_ZERO_STRETCH constraint holds since the size of the smallest full stretch of zero of the sequence 0 2 0 0 0 2 1 0 0 3 is greater than or equal to 2.

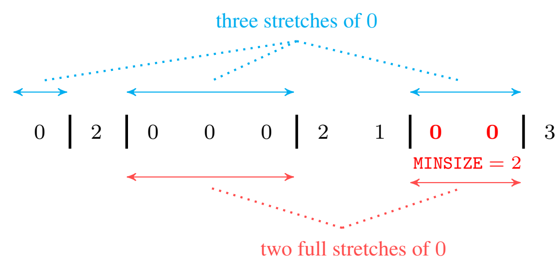

Figure 5.574: Illustration of the **Example** slot: smallest full stretch of zero in bold and red (MINSIZE $= 2$); note that the leftmost stretch of zero of size 1 is ignored since it is located at one of the two extremities of the sequence 0 2 0 0 0 2 1 0 0 3.

Typical

|VARIABLES| > 2
range(VARIABLES.var) > 1
|VARIABLES|−AMONG_DIFF_0(VARIABLES.var) > 1

Typical model

ATLEAST$(2, \texttt{VARIABLES}, 0)$

Symmetries

- Items of `VARIABLES` can be reversed.
- An occurrence of a value of `VARIABLES.var` that is different from 0 can be replaced by any other value that is also different from 0.

Counting

5.262 MIN_SIZE_SET_OF_CONSECUTIVE_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint MIN_SIZE_SET_OF_CONSECUTIVE_VAR(MIN, VARIABLES)

Arguments

```
MIN       : dvar
VARIABLES : collection(var-dvar)
```

Restrictions

$\texttt{MIN} \geq 1$
$\texttt{MIN} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose MIN is the size of the smallest set of variables of the collection VARIABLES that all take their values in a set of consecutive values.

Example

$(4, \langle 3, 1, 3, 7, 4, 1, 2, 8, 7, 6\rangle)$
$(4, \langle 3, 1, 3, 2\rangle)$

In the first example, the two parts $3, 1, 3, 4, 1, 2$ and $7, 8, 7, 6$ take respectively their values in the two following sets of consecutive values $\{1, 2, 3, 4\}$ and $\{6, 7, 8\}$. Consequently, the corresponding MIN_SIZE_SET_OF_CONSECUTIVE_VAR constraint holds since the cardinality of the smallest set of variables is 4.

Typical

$\texttt{MIN} > 1$
$\texttt{MIN} < |\texttt{VARIABLES}|$
$|\texttt{VARIABLES}| > 0$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: MIN determined by VARIABLES.

Graph property(ies)	**MIN_NSCC** = MIN

Graph model Since the arc constraint is symmetric each strongly connected component of the final graph corresponds exactly to one connected component of the final graph.

Parts (A) and (B) of Figure 5.577 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **MIN_NSCC** graph property, we show the smallest strongly connected component of the final graph.

5.263 MIN_SURF_PEAK

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin derived from PEAK

Constraint MIN_SURF_PEAK(MIN_SURF, VARIABLES)

Arguments

MIN_SURF : dvar
VARIABLES : collection(var−dvar)

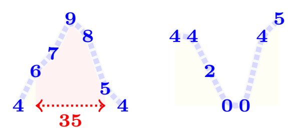
Restrictions

MIN_SURF ≥ 0
MIN_SURF $\leq$sum(VARIABLES.var)
required(VARIABLES, var)

Purpose Given a sequence VARIABLES constraint MIN_SURF to be fixed to the smallest surface of the different peaks, or to 0 if no peak exists.

Example

$(12, \langle 4, 4, 2, 2, 3, 5, 5, 6, 3, 1, 1, 2, 2, 2, 2, 2, 2, 1\rangle)$
$(35, \langle 4, 6, 7, 9, 8, 5, 4\rangle)$
$(0, \langle 4, 4, 2, 0, 0, 4, 5\rangle)$



The first MIN_SURF_PEAK constraint holds since the sequence 4 4 2 2 3 5 5 6 3 1 1 2 2 2 2 2 2 1 contains two peaks of respective surface 22 and 12 (see Figure 5.578) and since its argument MIN_SURF is fixed to the smallest value 12.

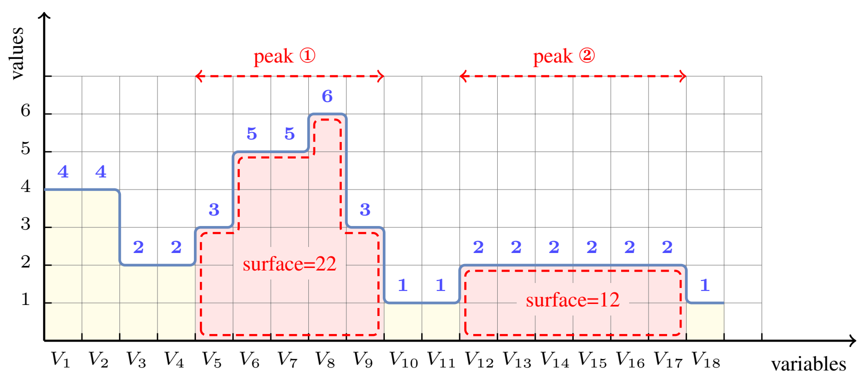


Figure 5.578: Illustration of the first example of the **Example** slot: a sequence of eighteen variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}, V_{11}, V_{12}, V_{13}, V_{14}, V_{15}, V_{16}, V_{17}, V_{18} respectively fixed to values 4, 4, 2, 2, 3, 5, 5, 6, 3, 1, 1, 2, 2, 2, 2, 2, 2, 1 and its two peaks of surface 22 and 12.

Typical

$\mathtt{MIN\_SURF} > 1$
$|\mathtt{VARIABLES}| > 2$

Typical model

$\mathtt{nval}(\mathtt{VARIABLES.var}) > 2$

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Functional dependency: MIN_SURF determined by VARIABLES.

See also

common keyword: MIN_WIDTH_PEAK, PEAK *(sequence)*.

Keywords

characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint arguments: reverse of a constraint, pure functional dependency.

modelling: functional dependency.

Automaton Figure 5.579 depicts the automaton associated with the MIN_SURF_PEAK constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $(\mathtt{VAR}_i < \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 0) \wedge (\mathtt{VAR}_i = \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 1) \wedge (\mathtt{VAR}_i > \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 2)$.

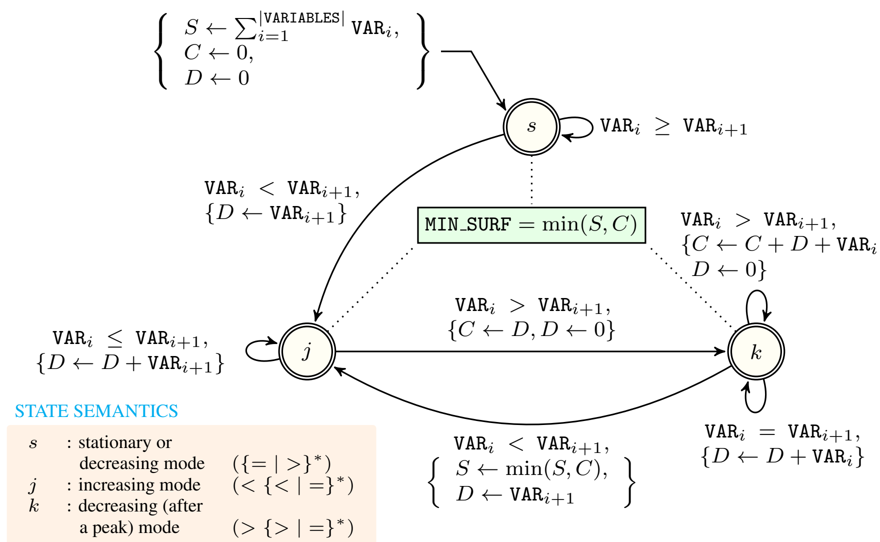

Figure 5.579: Automaton of the MIN_SURF_PEAK constraint: the start of the first potential peak is discovered while triggering the transition from s to j, the top of a peak is discovered while triggering the transition from j to k, the end of a peak and the start of the next potential peak are discovered while triggering the transition from k to j; the counters S, C and D respectively stand for *min_surface*, *current_surface* and *descending_plateau_surface*.

5.264 MIN_WIDTH_PEAK

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin derived from PEAK

Constraint MIN_WIDTH_PEAK(MIN_WIDTH, VARIABLES)

Synonym MIN_BASE_PEAK.

Arguments

MIN_WIDTH : dvar
VARIABLES : collection(var−dvar)

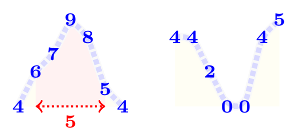
Restrictions

MIN_WIDTH ≥ 0
MIN_WIDTH $\leq$ |VARIABLES| $- 2$
required(VARIABLES, var)

Purpose Given a sequence VARIABLES constraint MIN_WIDTH to be fixed to the width of the smallest peak, or to 0 if no peak exists.

Example

$(5, \langle 4, 4, 2, 2, 3, 5, 5, 6, 3, 1, 1, 2, 2, 2, 2, 2, 2, 1\rangle)$
$(5, \langle 4, 6, 7, 9, 8, 5, 4\rangle)$
$(0, \langle 4, 4, 2, 0, 0, 4, 5\rangle)$



The first MIN_WIDTH_PEAK constraint holds since the sequence 4 4 2 2 3 5 5 6 3 1 1 2 2 2 2 2 2 1 contains two peaks of respective width 5 and 6 (see Figure 5.581) and since its argument MIN_WIDTH is fixed to the smallest value 5.

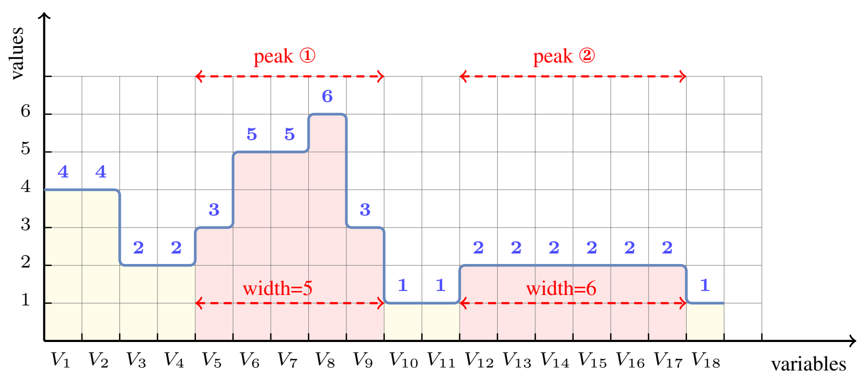


Figure 5.581: Illustration of the first example of the **Example** slot: a sequence of eighteen variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}, V_{11}, V_{12}, V_{13}, V_{14}, V_{15}, V_{16}, V_{17}, V_{18} respectively fixed to values 4, 4, 2, 2, 3, 5, 5, 6, 3, 1, 1, 2, 2, 2, 2, 2, 2, 1 and its two peaks of width 5 and 6.

Typical

MIN_WIDTH > 1
$|$VARIABLES$| > 2$

Typical model

nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Functional dependency: MIN_WIDTH determined by VARIABLES.

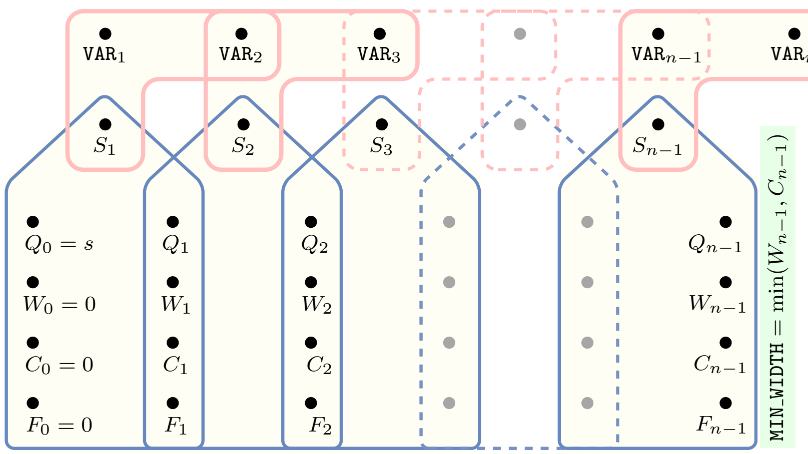

Figure 5.585: Hypergraph of the reformulation corresponding to the automaton of the MIN_WIDTH_PEAK constraint

5.265 MIN_WIDTH_PLATEAU

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin

Derived from PEAK.

Constraint

MIN_WIDTH_PLATEAU(MIN_WIDTH, VARIABLES)

Arguments

MIN_WIDTH : dvar
VARIABLES : collection(var−dvar)

Restrictions

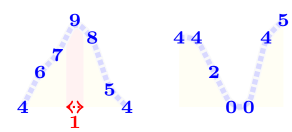
MIN_WIDTH ≥ 0
MIN_WIDTH $\leq$ |VARIABLES| $- 2$
required(VARIABLES, var)

Purpose

Given a sequence VARIABLES constraint MIN_WIDTH to be fixed to the width of the smallest plateau, or to 0 if no peak exists. A *plateau* corresponds to the highest portion of a peak.

Example

$(3, \langle 4, 4, 2, 2, 3, 5, 6, 6, 6, 1, 1, 2, 2, 2, 2, 2, 2, 1\rangle)$
$(1, \langle 4, 6, 7, 9, 8, 5, 4\rangle)$
$(0, \langle 4, 4, 2, 0, 0, 4, 5\rangle)$



The first MIN_WIDTH_PLATEAU constraint holds since the sequence 4 4 2 2 3 5 6 6 6 1 1 2 2 2 2 2 2 1 contains two peaks with two plateaux of respective width 3 and 6 (see Figure 5.586) and since its argument MIN_WIDTH is fixed to the smallest value 3.

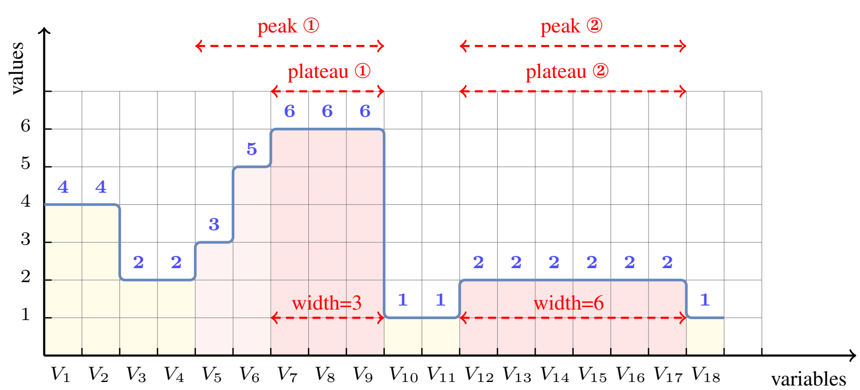


Figure 5.586: Illustration of the first example of the **Example** slot: a sequence of eighteen variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}, V_{11}, V_{12}, V_{13}, V_{14}, V_{15}, V_{16}, V_{17}, V_{18} respectively fixed to values 4, 4, 2, 2, 3, 5, 6, 6, 6, 1, 1, 2, 2, 2, 2, 2, 2, 1 and its two peaks with two plateaux of width 3 and 6.

Typical

$|\texttt{VARIABLES}| > 2$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

Typical model

$\texttt{nval}(\texttt{VARIABLES.var}) > 2$

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Functional dependency: MIN_WIDTH determined by VARIABLES.

See also

common keyword: MIN_WIDTH_PEAK *(sequence)*.

Keywords

characteristic of a constraint: automaton, automaton with counters.

combinatorial object: sequence.

constraint arguments: reverse of a constraint, pure functional dependency.

modelling: functional dependency.

Automaton Figure 5.587 depicts the automaton associated with the MIN_WIDTH_PLATEAU constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $(\mathtt{VAR}_i < \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 0) \wedge (\mathtt{VAR}_i = \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 1) \wedge (\mathtt{VAR}_i > \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 2)$.

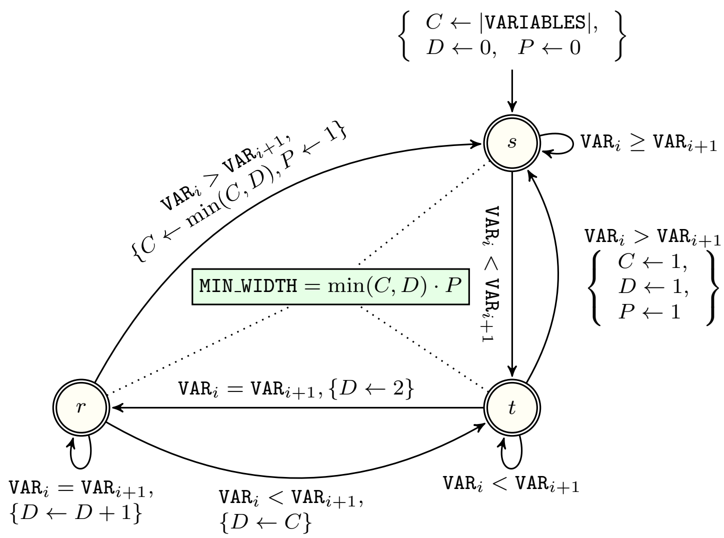

Figure 5.587: Automaton for the MIN_WIDTH_PLATEAU constraint; states s, t and r respectively correspond to a *decreasing or stationary state*, to an *increasing state* and to a *potential plateau*; counters C, D and P respectively correspond to the size of the smallest plateau encountered so far, to the size of the current potential plateau and to the fact that we already encountered at least one plateau; the transition from r to t cancels out the effect of D on the final result by resetting D to the current value of C.

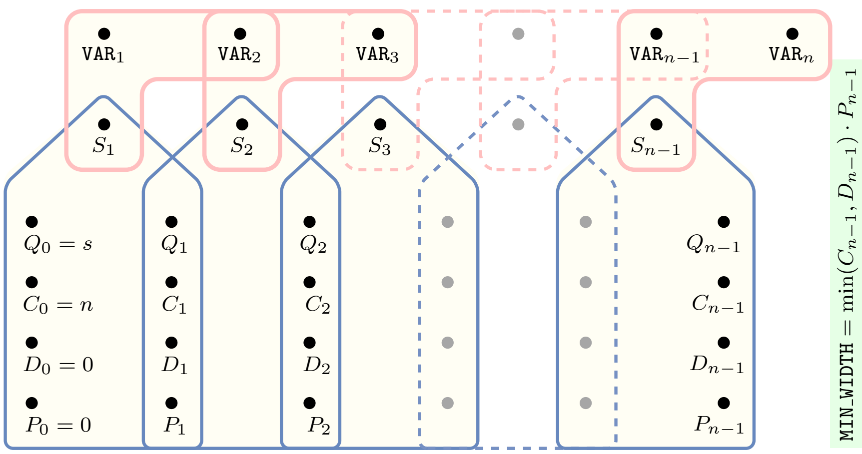

Figure 5.588: Hypergraph of the reformulation corresponding to the automaton of the MIN_WIDTH_PLATEAU constraint

5.266 MIN_WIDTH_VALLEY

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin derived from VALLEY

Constraint MIN_WIDTH_VALLEY(MIN_WIDTH, VARIABLES)

Synonym MIN_BASE_VALLEY.

Arguments

MIN_WIDTH : dvar
VARIABLES : collection(var−dvar)

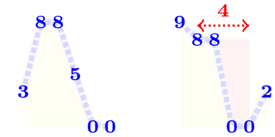
Restrictions

$\text{MIN\_WIDTH} \geq 0$
$\text{MIN\_WIDTH} \leq |\text{VARIABLES}| - 2$
required(VARIABLES, var)

Purpose Given a sequence VARIABLES constraint MIN_WIDTH to be fixed to the width of the smallest valley, or to 0 if no valley exists.

Example

$(5, \langle 3, 3, 5, 5, 4, 2, 2, 3, 4, 6, 6, 5, 5, 5, 5, 5, 5, 6\rangle)$
$(0, \langle 3, 8, 8, 5, 0, 0\rangle)$
$(4, \langle 9, 8, 8, 0, 0, 2\rangle)$



The first MIN_WIDTH_VALLEY constraint holds since the sequence 3 3 5 5 4 2 2 3 4 6 6 5 5 5 5 5 5 6 contains two valleys of respective width 5 and 6 (see Figure 5.589) and since its argument MIN_WIDTH is fixed to the smallest value 5.

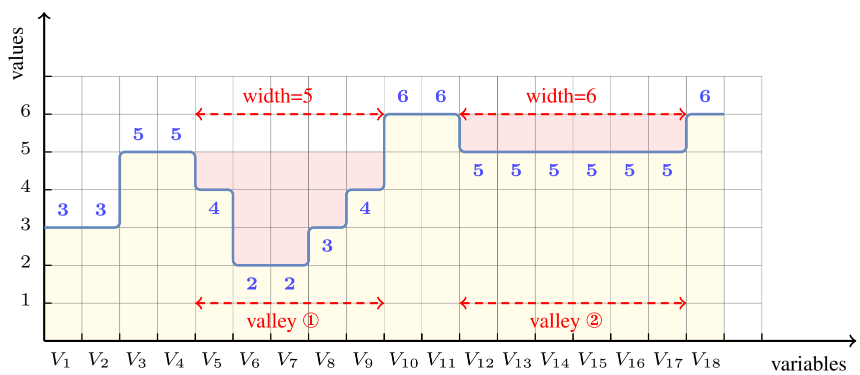


Figure 5.589: Illustration of the first example of the **Example** slot: a sequence of eighteen variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}, V_{11}, V_{12}, V_{13}, V_{14}, V_{15}, V_{16}, V_{17}, V_{18} respectively fixed to values 3, 3, 5, 5, 4, 2, 2, 3, 4, 6, 6, 5, 5, 5, 5, 5, 5, 6 and its two valleys of width 5 and 6.

Typical

MIN_WIDTH > 1
$|$VARIABLES$| > 2$

Typical model

nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Functional dependency: MIN_WIDTH determined by VARIABLES.

5.267 MINIMUM

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint MINIMUM(MIN, VARIABLES)

Synonym MIN.

Arguments

MIN	:	dvar
VARIABLES	:	collection(var−dvar)

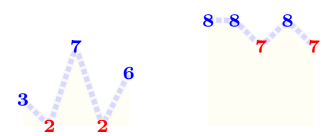
Restrictions

$|$VARIABLES$| > 0$
required(VARIABLES, var)

Purpose MIN is the minimum value of the collection of domain variables VARIABLES.

Example

$(2, \langle 3, 2, 7, 2, 6\rangle)$
$(7, \langle 8, 8, 7, 8, 7\rangle)$



The first MINIMUM constraint holds since its first argument MIN $= 2$ is set to the minimum value of the collection $\langle 3, 2, 7, 2, 6\rangle$.

Typical

$|$VARIABLES$| > 1$
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to MIN as well as to the var attribute of all items of VARIABLES.

Arg. properties

- Functional dependency: MIN determined by VARIABLES.
- Aggregate: MIN(min), VARIABLES(union).

Usage In some project scheduling problems one has to introduce dummy activities that correspond, for example, to the starting time of a given set of activities. In this context one can use the MINIMUM constraint to get the minimum starting time of a set of tasks.

Remark Note that MINIMUM is a constraint and not just a function that computes the minimum value of a collection of variables: potential values of MIN influence the variables of VARIABLES, and reciprocally potential values that can be assigned to variables of VARIABLES influence MIN.

The MINIMUM constraint is called MIN in **JaCoP** (http://www.jacop.eu/).

Algorithm A filtering algorithm for the MINIMUM constraint is described in [29].

The MINIMUM constraint is entailed if all the following conditions hold:

1. `MIN` is fixed.
2. At least one variable of `VARIABLES` is assigned value `MIN`.
3. All variables of `VARIABLES` have their minimum values greater than or equal to value `MIN`.

Cond. implications

MINIMUM(MIN, VARIABLES)
with $\texttt{first}(\texttt{VARIABLES.var}) > \texttt{MIN}$
and $\texttt{last}(\texttt{VARIABLES.var}) > \texttt{MIN}$
implies DEEPEST_VALLEY(DEPTH, VARIABLES).

Arc input(s)	VARIABLES
Arc generator	*CLIQUE* $\mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	$\bigvee\begin{pmatrix} \texttt{variables1.key} = \texttt{variables2.key}, \\ \texttt{variables1.var} < \texttt{variables2.var} \end{pmatrix}$
Graph property(ies)	**ORDER**(0, MAXINT, var) = MIN

Graph model The condition variables1.key = variables2.key holds if and only if variables1 and variables2 corresponds to the same vertex. It is used in order to enforce to keep all the vertices of the initial graph. **ORDER**(0, MAXINT, var) refers to the source vertices of the graph, i.e., those vertices that do not have any predecessor.

Parts (A) and (B) of Figure 5.594 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **ORDER** graph property, the vertices of rank 0 (without considering the loops) of the final graph are outlined with a thick circle.

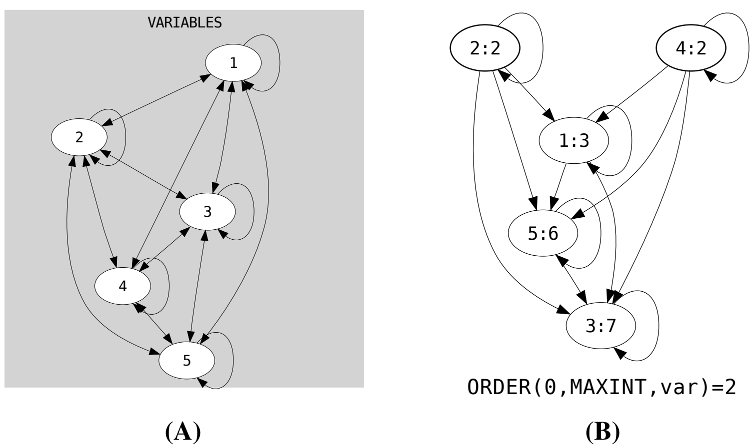

Figure 5.594: Initial and final graph of the MINIMUM constraint

Automaton Figure 5.595 depicts a first counter free deterministic automaton associated with the MINIMUM constraint. Let $\texttt{VAR}_i$ be the i^{th} variable of the VARIABLES collection. To each pair $(\texttt{MIN}, \texttt{VAR}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\texttt{MIN} < \texttt{VAR}_i \Leftrightarrow S_i = 0) \wedge (\texttt{MIN} = \texttt{VAR}_i \Leftrightarrow S_i = 1) \wedge (\texttt{MIN} > \texttt{VAR}_i \Leftrightarrow S_i = 2)$.

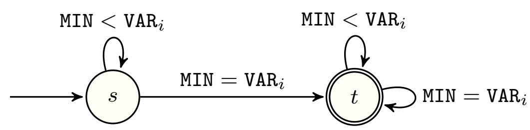

Figure 5.595: Counter free automaton of the MINIMUM constraint

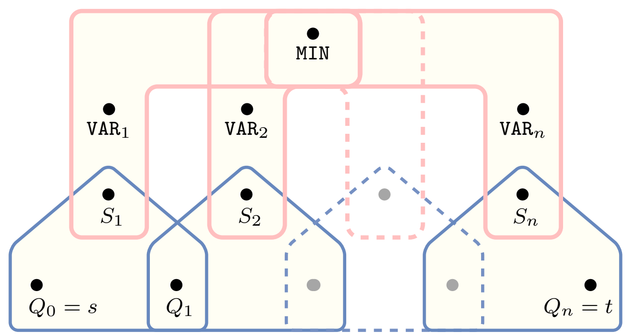

Figure 5.596: Hypergraph of the reformulation corresponding to the counter free automaton of the MINIMUM constraint

Figure 5.597 depicts a second counter free non deterministic automaton associated with the MINIMUM constraint, where the argument MIN is also part of the sequence passed to the automaton.

Figure 5.599 depicts a third deterministic automaton with one counter associated with the MINIMUM constraint, where the argument MIN is unified to the final value of the counter.

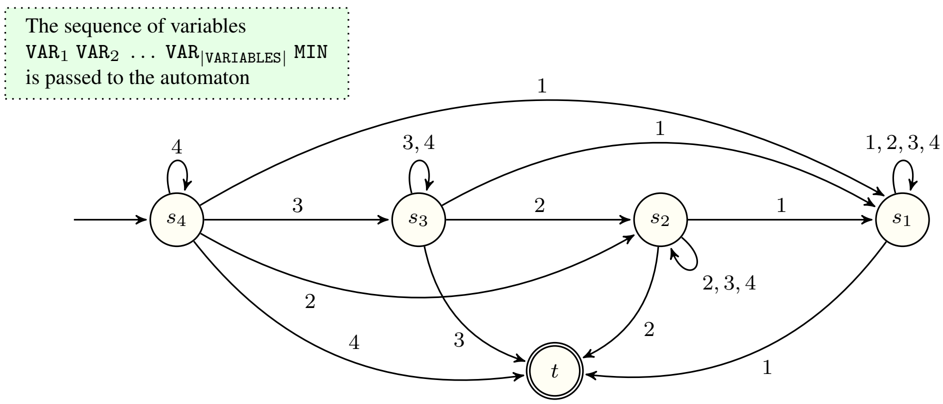

Figure 5.597: Counter free non deterministic automaton of the MINIMUM(MIN, VARIABLES) constraint assuming that the union of the domain of the variables is the set $\{1, 2, 3, 4\}$ and that the elements of VARIABLES are first passed to the automaton followed by MIN (state s_i means that no value strictly less than value i was found and that value i was already encountered at least once)

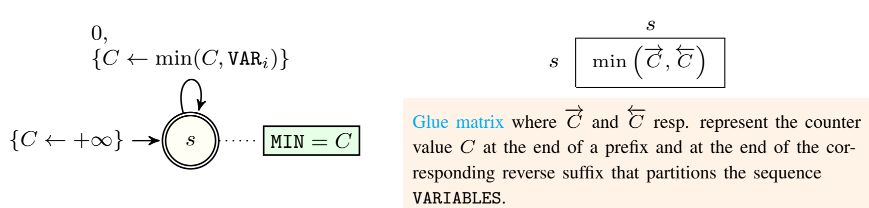

Figure 5.599: Automaton (with one counter) of the MINIMUM constraint and its glue matrix

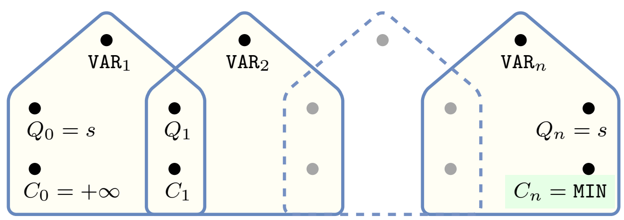

Figure 5.600: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the MINIMUM constraint: since all states variables $Q_0, Q_1, \ldots, Q_n$ are fixed to the unique state s of the automaton, the transitions constraints share only the counter variable C and the constraint network is Berge-acyclic

5.268 MINIMUM_EXCEPT_0

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin

Derived from MINIMUM.

Constraint

MINIMUM_EXCEPT_0(MIN, VARIABLES, DEFAULT)

Arguments

MIN	:	dvar
VARIABLES	:	collection(var−dvar)
DEFAULT	:	int

Restrictions

MIN > 0
MIN $\leq$ DEFAULT
$|$VARIABLES$| > 0$
required(VARIABLES, var)
VARIABLES.var ≥ 0
VARIABLES.var $\leq$ DEFAULT
DEFAULT > 0

Purpose

All variables of the collection VARIABLES are assigned a value that belongs to interval $[0, \mathtt{DEFAULT}]$. MIN is the minimum value of the collection of domain variables VARIABLES, ignoring all variables that take 0 as value. When all variables of the collection VARIABLES are assigned value 0, MIN is set to the default value DEFAULT.

Example

$(3, \langle 3, 7, 6, 7, 4, 7 \rangle, 1000000)$
$(2, \langle 3, 2, 0, 7, 2, 6 \rangle, 1000000)$
$(1000000, \langle 0, 0, 0, 0, 0, 0 \rangle, 1000000)$

The three examples of the MINIMUM_EXCEPT_0 constraint respectively hold since:

- Within the first example, MIN is set to the minimum value 3 of the collection $\langle 3, 7, 6, 7, 4, 7 \rangle$.
- Within the second example, MIN is set to the minimum value 2 (ignoring value 0) of the collection $\langle 3, 2, 0, 7, 2, 6 \rangle$.
- Finally within the third example, MIN is set to the default value 1000000 since all items of the collection $\langle 0, 0, 0, 0, 0, 0 \rangle$ are set to 0.

Typical

$|$VARIABLES$| > 1$
range(VARIABLES.var) > 1
ATLEAST(1, VARIABLES, 0)

Typical model

nval(VARIABLES.var) > 2
ATLEAST(2, VARIABLES, 0)

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.

Arg. properties

Functional dependency: MIN determined by VARIABLES and DEFAULT.

Remark

The joker value 0 makes sense only because we restrict the variables of the VARIABLES collection to take non-negative values.

Reformulation

By (1) associating to each variable V_i $(i \in [1, |\mathtt{VARIABLES}|])$ of the VARIABLES collection a *rank* variable $R_i \in [0, |\mathtt{VARIABLES}|-1]$ with the reified constraint $R_i = 1 \Leftrightarrow V_i = \mathtt{MIN}$, and by creating for each pair of variables V_i, V_j $(i, j < i \in [1, |\mathtt{VARIABLES}|])$ the reified constraints

$V_i < V_j \Leftrightarrow R_i < R_j$,
$V_i = V_j \Leftrightarrow R_i = R_j$,
$V_i > V_j \Leftrightarrow R_i > R_j$,

and by (2) creating the reified constraint

$V_1 = 0 \wedge V_2 = 0 \wedge \cdots \wedge V_n = 0 \Rightarrow \mathtt{MIN} = \mathtt{DEFAULT}$,

one can reformulate the MINIMUM_EXCEPT_0 constraint in term of $3 \cdot \frac{|\mathtt{VARIABLES}| \cdot (|\mathtt{VARIABLES}|-1)}{2} + 2$ reified constraints.

See also

hard version: MINIMUM *(value* 0 *is not ignored any more)*.

Keywords

characteristic of a constraint: joker value, minimum, automaton, automaton without counters, reified automaton constraint.

constraint arguments: pure functional dependency.

constraint network structure: centered cyclic(1) constraint network(1).

constraint type: order constraint.

modelling: functional dependency.

Cond. implications

MINIMUM_EXCEPT_0(MIN, VARIABLES, DEFAULT)
with maxval(VARIABLES.var) $<$ DEFAULT
implies ATMOST(N, VARIABLES, VALUE).

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	• variables1.var $\neq 0$ • variables2.var $\neq 0$ • $\bigvee \begin{pmatrix} \texttt{variables1.key} = \texttt{variables2.key}, \\ \texttt{variables1.var} < \texttt{variables2.var} \end{pmatrix}$
Graph property(ies)	**ORDER**(0, DEFAULT, var) = MIN

Graph model Because of the first two conditions of the arc constraint, all vertices that correspond to 0 will be removed from the final graph.

Parts (A) and (B) of Figure 5.601 respectively show the initial and final graph of the second example of the **Example** slot. Since we use the **ORDER** graph property, the vertices of rank 0 (without considering the loops) of the final graph are outlined with a thick circle.

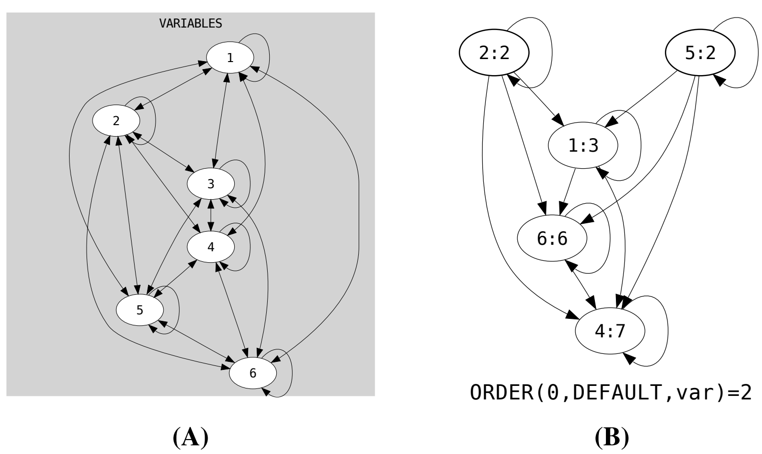

Figure 5.601: Initial and final graph of the MINIMUM_EXCEPT_0 constraint

Since the graph associated with the third example does not contain any vertex, **ORDER** returns the default value DEFAULT.

Automaton Figure 5.602 depicts the automaton associated with the MINIMUM_EXCEPT_0 constraint. Let $\texttt{VAR}_i$ be the i^{th} variable of the VARIABLES collection. To each pair $(\texttt{MIN}, \texttt{VAR}_i)$ corresponds a signature variable S_i as well as the following signature constraint:

$((\texttt{VAR}_i = 0) \wedge (\texttt{MIN} \neq \texttt{DEFAULT})) \Leftrightarrow S_i = 0 \wedge$

$((\texttt{VAR}_i = 0) \wedge (\texttt{MIN} = \texttt{DEFAULT})) \Leftrightarrow S_i = 1 \wedge$

$((\texttt{VAR}_i \neq 0) \wedge (\texttt{MIN} = \texttt{VAR}_i)) \Leftrightarrow S_i = 2 \wedge$

$((\texttt{VAR}_i \neq 0) \wedge (\texttt{MIN} < \texttt{VAR}_i)) \Leftrightarrow S_i = 3 \wedge$

$((\texttt{VAR}_i \neq 0) \wedge (\texttt{MIN} > \texttt{VAR}_i)) \Leftrightarrow S_i = 4.$

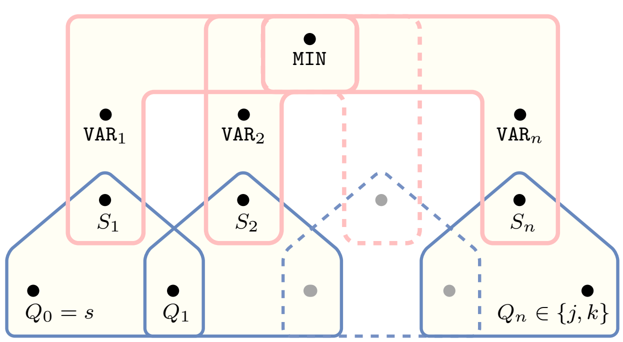

Figure 5.603: Hypergraph of the reformulation corresponding to the automaton of the MINIMUM_EXCEPT_0 constraint

5.269 MINIMUM_GREATER_THAN

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin N. Beldiceanu

Constraint MINIMUM_GREATER_THAN(VAR1, VAR2, VARIABLES)

Arguments

VAR1 : dvar
VAR2 : dvar
VARIABLES : collection(var−dvar)

Restrictions

VAR1 $>$ VAR2
$|$VARIABLES$| > 0$
required(VARIABLES, var)

Purpose VAR1 is the smallest value strictly greater than VAR2 of the collection of variables VARIABLES: this concretely means that there exists at least one variable of VARIABLES that takes a value strictly greater than VAR2.

Example $(5, 3, \langle 8, 5, 3, 8\rangle)$

The MINIMUM_GREATER_THAN constraint holds since value 5 is the smallest value strictly greater than value 3 among values $8, 5, 3$ and 8.

Typical

$|$VARIABLES$| > 1$
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetry Items of VARIABLES are permutable.

Arg. properties Aggregate: VAR1(min), VAR2(id), VARIABLES(union).

Reformulation Let $V_1, V_2, \ldots, V_{|\texttt{VARIABLES}|}$ denote the variables of the collection of variables VARIABLES. By creating the extra variables M and $U_1, U_2, \ldots, U_{|\texttt{VARIABLES}|}$, the MINIMUM_GREATER_THAN constraint can be expressed in term of the following constraints:

1. MAXIMUM(M, VARIABLES),
2. VAR1 $>$ VAR2,
3. VAR1 $\leq M$,
4. $V_i \leq$ VAR2 $\Rightarrow U_i = M \quad (i \in [1, |\texttt{VARIABLES}|])$,
5. $V_i >$ VAR2 $\Rightarrow U_i = V_i \quad (i \in [1, |\texttt{VARIABLES}|])$,

6. MINIMUM(VAR1, $\langle U_1, U_2, \ldots, U_{|\text{VARIABLES}|}\rangle$).

See also

common keyword: NEXT_GREATER_ELEMENT *(order constraint)*.

implied by: NEXT_GREATER_ELEMENT.

related: NEXT_ELEMENT *(identify an element in a table)*.

Keywords

characteristic of a constraint: minimum, automaton, automaton without counters, reified automaton constraint, derived collection.

constraint network structure: centered cyclic(2) constraint network(1).

constraint type: order constraint.

Derived Collection	col(ITEM−collection(var−dvar), [item(var − VAR2)])
Arc input(s)	ITEM VARIABLES
Arc generator	*PRODUCT*↦collection(item, variables)
Arc arity	2
Arc constraint(s)	item.var < variables.var
Graph property(ies)	**NARC**> 0
Sets	SUCC ↦ [source, variables]
Constraint(s) on sets	MINIMUM(VAR1, variables)

Graph model

Similar to the NEXT_GREATER_ELEMENT constraint, except that there is no order on the variables of the collection VARIABLES.

Parts (A) and (B) of Figure 5.604 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold. The source and the sinks of the final graph respectively correspond to the variable VAR2 and to the variables of the VARIABLES collection that are strictly greater than VAR2. VAR1 is set to the smallest value of the var attribute of the sinks of the final graph.

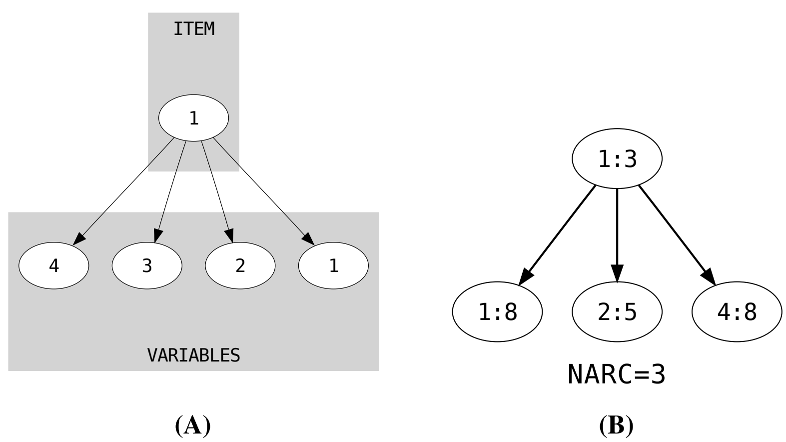

Figure 5.604: Initial and final graph of the MINIMUM_GREATER_THAN constraint

Automaton Figure 5.605 depicts the automaton associated with the MINIMUM_GREATER_THAN constraint. Let $\mathtt{VAR}_i$ be the i^{th} variable of the VARIABLES collection. To each triple $(\mathtt{VAR1}, \mathtt{VAR2}, \mathtt{VAR}_i)$ corresponds a signature variable S_i as well as the following signature constraint:

$((\mathtt{VAR}_i < \mathtt{VAR1}) \wedge (\mathtt{VAR}_i \leq \mathtt{VAR2})) \Leftrightarrow S_i = 0 \wedge$

$((\mathtt{VAR}_i = \mathtt{VAR1}) \wedge (\mathtt{VAR}_i \leq \mathtt{VAR2})) \Leftrightarrow S_i = 1 \wedge$

$((\mathtt{VAR}_i > \mathtt{VAR1}) \wedge (\mathtt{VAR}_i \leq \mathtt{VAR2})) \Leftrightarrow S_i = 2 \wedge$

$((\mathtt{VAR}_i < \mathtt{VAR1}) \wedge (\mathtt{VAR}_i > \mathtt{VAR2})) \Leftrightarrow S_i = 3 \wedge$

$((\mathtt{VAR}_i = \mathtt{VAR1}) \wedge (\mathtt{VAR}_i > \mathtt{VAR2})) \Leftrightarrow S_i = 4 \wedge$

$((\mathtt{VAR}_i > \mathtt{VAR1}) \wedge (\mathtt{VAR}_i > \mathtt{VAR2})) \Leftrightarrow S_i = 5.$

The automaton is constructed in order to fulfil the following conditions:

- We look for an item of the VARIABLES collection such that $\mathtt{var}_i = \mathtt{VAR1}$ and $\mathtt{var}_i > \mathtt{VAR2}$,
- There should not exist any item of the VARIABLES collection such that $\mathtt{var}_i < \mathtt{VAR1}$ and $\mathtt{var}_i > \mathtt{VAR2}$.

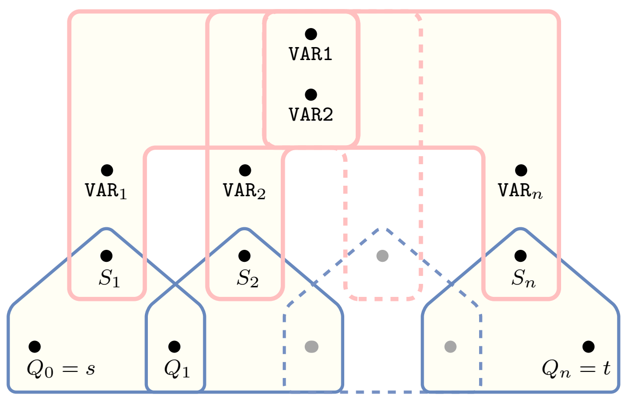

Figure 5.606: Hypergraph of the reformulation corresponding to the counter free non deterministic automaton of the MINIMUM_GREATER_THAN constraint

5.270 MINIMUM_MODULO

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from MINIMUM.

Constraint MINIMUM_MODULO(MIN, VARIABLES, M)

Arguments

```
MIN       : dvar
VARIABLES : collection(var-dvar)
M         : int
```

Restrictions

$|\mathtt{VARIABLES}| > 0$
$\mathtt{M} > 0$
required(VARIABLES, var)

Purpose MIN is a minimum value of the collection of domain variables VARIABLES according to the following partial ordering: $(X \bmod \mathtt{M}) < (Y \bmod \mathtt{M})$.

Example

$(6, \langle 9, 1, 7, 6, 5\rangle, 3)$
$(9, \langle 9, 1, 7, 6, 5\rangle, 3)$

The MINIMUM_MODULO constraints hold since MIN is respectively set to values 6 and 9, where $6 \bmod 3 = 0$ and $9 \bmod 3 = 0$ are both less than or equal to all the expressions $9 \bmod 3 = 0$, $1 \bmod 3 = 1$, $7 \bmod 3 = 1$, $6 \bmod 3 = 0$, and $5 \bmod 3 = 2$.

Typical

$|\mathtt{VARIABLES}| > 1$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 1$
$\mathtt{M} > 1$
$\mathtt{M} < \mathtt{maxval}(\mathtt{VARIABLES.var})$

Symmetry Items of VARIABLES are permutable.

Arg. properties Functional dependency: MIN determined by VARIABLES and M.

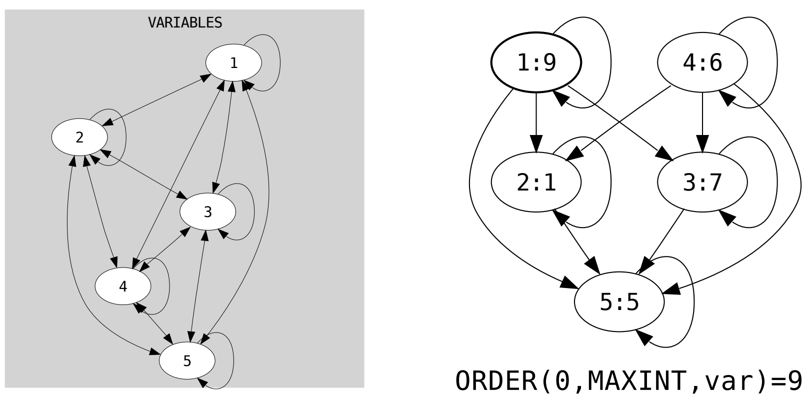
See also **comparison swapped:** MAXIMUM_MODULO.
specialisation: MINIMUM *(*variable mod constant *replaced by* variable*)*.

Keywords **characteristic of a constraint:** modulo, maxint, minimum.
constraint arguments: pure functional dependency.
constraint type: order constraint.
modelling: functional dependency.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	$\bigvee \left(\begin{array}{l} \texttt{variables1.key} = \texttt{variables2.key}, \\ \texttt{variables1.var} \bmod \texttt{M} < \texttt{variables2.var} \bmod \texttt{M} \end{array} \right)$
Graph property(ies)	**ORDER**(0, MAXINT, var) = MIN

Graph model We use a similar definition that the one that was utilised for the MINIMUM constraint. Within the arc constraint we replace the condition $X < Y$ by the condition $(X \bmod \texttt{M}) < (Y \bmod \texttt{M})$.

Parts (A) and (B) of Figure 5.607 respectively show the initial and final graph associated with the second example of the **Example** slot. Since we use the **ORDER** graph property, the vertex of rank 0 (without considering the loops) associated with value 9 is outlined with a thick circle.



(A) **(B)**

Figure 5.607: Initial and final graph of the MINIMUM_MODULO constraint

5.271 MINIMUM_WEIGHT_ALLDIFFERENT

DESCRIPTION LINKS GRAPH

Origin [182]

Constraint MINIMUM_WEIGHT_ALLDIFFERENT(VARIABLES, MATRIX, COST)

Synonyms MINIMUM_WEIGHT_ALLDIFF, MINIMUM_WEIGHT_ALLDISTINCT, MIN_WEIGHT_ALLDIFF, MIN_WEIGHT_ALLDIFFERENT, MIN_WEIGHT_ALLDISTINCT.

Arguments

VARIABLES	:	collection(var−dvar)
MATRIX	:	collection(i−int, j−int, c−int)
COST	:	dvar

Restrictions

$|\texttt{VARIABLES}| > 0$
required(VARIABLES, var)
$\texttt{VARIABLES.var} \geq 1$
$\texttt{VARIABLES.var} \leq |\texttt{VARIABLES}|$
required(MATRIX, [i, j, c])
increasing_seq(MATRIX, [i, j])
$\texttt{MATRIX.i} \geq 1$
$\texttt{MATRIX.i} \leq |\texttt{VARIABLES}|$
$\texttt{MATRIX.j} \geq 1$
$\texttt{MATRIX.j} \leq |\texttt{VARIABLES}|$
$|\texttt{MATRIX}| = |\texttt{VARIABLES}| * |\texttt{VARIABLES}|$

Purpose

All variables of the VARIABLES collection should take a distinct value located within interval $[1, |\texttt{VARIABLES}|]$. In addition COST is equal to the sum of the costs associated with the fact that we assign value i to variable j. These costs are given by the matrix MATRIX.

Example

$$\left(\begin{array}{l}\langle 2,3,1,4\rangle, \\ \left\langle\begin{array}{lll} \mathtt{i}-1 & \mathtt{j}-1 & \mathtt{c}-4, \\ \mathtt{i}-1 & \mathtt{j}-2 & \mathtt{c}-1, \\ \mathtt{i}-1 & \mathtt{j}-3 & \mathtt{c}-7, \\ \mathtt{i}-1 & \mathtt{j}-4 & \mathtt{c}-0, \\ \mathtt{i}-2 & \mathtt{j}-1 & \mathtt{c}-1, \\ \mathtt{i}-2 & \mathtt{j}-2 & \mathtt{c}-0, \\ \mathtt{i}-2 & \mathtt{j}-3 & \mathtt{c}-8, \\ \mathtt{i}-2 & \mathtt{j}-4 & \mathtt{c}-2, \\ \mathtt{i}-3 & \mathtt{j}-1 & \mathtt{c}-3, \\ \mathtt{i}-3 & \mathtt{j}-2 & \mathtt{c}-2, \\ \mathtt{i}-3 & \mathtt{j}-3 & \mathtt{c}-1, \\ \mathtt{i}-3 & \mathtt{j}-4 & \mathtt{c}-6, \\ \mathtt{i}-4 & \mathtt{j}-1 & \mathtt{c}-0, \\ \mathtt{i}-4 & \mathtt{j}-2 & \mathtt{c}-0, \\ \mathtt{i}-4 & \mathtt{j}-3 & \mathtt{c}-6, \\ \mathtt{i}-4 & \mathtt{j}-4 & \mathtt{c}-5 \end{array}\right\rangle, 17\end{array}\right)$$

The MINIMUM_WEIGHT_ALLDIFFERENT constraint holds since the cost 17 corresponds to the sum $\mathtt{MATRIX}[(1-1)\cdot 4+2].\mathtt{c}+\mathtt{MATRIX}[(2-1)\cdot 4+3].\mathtt{c}+\mathtt{MATRIX}[(3-1)\cdot 4+1].\mathtt{c}+\mathtt{MATRIX}[(4-1)\cdot 4+4].\mathtt{c} = \mathtt{MATRIX}[2].\mathtt{c}+\mathtt{MATRIX}[7].\mathtt{c}+\mathtt{MATRIX}[9].\mathtt{c}+\mathtt{MATRIX}[16].\mathtt{c} = 1+8+3+5$.

All solutions

Figure 5.608 gives all solutions to the following non ground instance of the MINIMUM_WEIGHT_ALLDIFFERENT constraint:
$\mathtt{V}_1 \in [2,4]$, $\mathtt{V}_2 \in [2,3]$, $\mathtt{V}_3 \in [1,6]$, $\mathtt{V}_4 \in [2,5]$, $\mathtt{V}_5 \in [2,3]$, $\mathtt{V}_6 \in [1,6]$, $\mathtt{V} \in [0,25]$,
MINIMUM_WEIGHT_ALLDIFFERENT$(\langle \mathtt{V}_1,\mathtt{V}_2,\mathtt{V}_3,\mathtt{V}_4,\mathtt{V}_5,\mathtt{V}_6\rangle,$
$\langle 1\,1\,5,\ 1\,2\,0,\ 1\,3\,1,\ 1\,4\,1,\ 1\,5\,3,\ 1\,6\,0,$
$2\,1\,2,\ 2\,2\,7,\ 2\,3\,0,\ 2\,4\,2,\ 2\,5\,5,\ 2\,6\,1,$
$3\,1\,3,\ 3\,2\,3,\ 3\,3\,6,\ 3\,4\,6,\ 3\,5\,0,\ 3\,6\,9,$
$4\,1\,4,\ 4\,2\,3,\ 4\,3\,0,\ 4\,4\,0,\ 4\,5\,0,\ 4\,6\,2,$
$5\,1\,2,\ 5\,2\,0,\ 5\,3\,6,\ 5\,4\,3,\ 5\,5\,7,\ 5\,6\,2,$
$6\,1\,5,\ 6\,2\,4,\ 6\,3\,5,\ 6\,4\,4,\ 6\,5\,5,\ 6\,6\,4\rangle, \mathtt{C})$.

Typical

$|\mathtt{VARIABLES}| > 1$
$\mathrm{range}(\mathtt{MATRIX.c}) > 1$
$\mathtt{MATRIX.c} > 0$

Arg. properties

Functional dependency: COST determined by VARIABLES and MATRIX.

Algorithm

The Hungarian method for the assignment problem [254] can be used for evaluating the bounds of the COST variable. A filtering algorithm is described in [388]. It can be used for handling both side of the MINIMUM_WEIGHT_ALLDIFFERENT constraint:

- Evaluating a lower bound of the COST variable and pruning the variables of the VARIABLES collection in order to not exceed the maximum value of COST.
- Evaluating an upper bound of the COST variable and pruning the variables of the VARIABLES collection in order to not be under the minimum value of COST.

Arc input(s) VARIABLES

Arc generator $CLIQUE \mapsto$ collection(variables1, variables2)

Arc arity 2

Arc constraint(s) variables1.var = variables2.key

Graph property(ies)
- **NTREE** = 0
- **SUM_WEIGHT_ARC** $\left(\texttt{MATRIX} \left[\sum \left(\begin{array}{l} (\texttt{variables1.key} - 1) * |\texttt{VARIABLES}|, \\ \texttt{variables1.var} \end{array} \right) \right] \texttt{.c} \right) = \texttt{COST}$

Graph model Since each variable takes one value, and because of the arc constraint variables1 = variables.key, each vertex of the initial graph belongs to the final graph and has exactly one successor. Therefore the sum of the out-degrees of the vertices of the final graph is equal to the number of vertices of the final graph. Since the sum of the in-degrees is equal to the sum of the out-degrees, it is also equal to the number of vertices of the final graph. Since **NTREE** = 0, each vertex of the final graph belongs to a circuit. Therefore each vertex of the final graph has at least one predecessor. Since we saw that the sum of the in-degrees is equal to the number of vertices of the final graph, each vertex of the final graph has exactly one predecessor. We conclude that the final graph consists of a set of vertex-disjoint elementary circuits.

Finally the graph constraint expresses that the COST variable is equal to the sum of the elementary costs associated with each variable-value assignment. All these elementary costs are recorded in the MATRIX collection. More precisely, the cost c_{ij} is recorded in the attribute c of the $((i-1) \cdot |\texttt{VARIABLES}| + j)^{th}$ entry of the MATRIX collection. This is ensured by the increasing restriction that enforces that the items of the MATRIX collection are sorted in lexicographically increasing order according to attributes i and j.

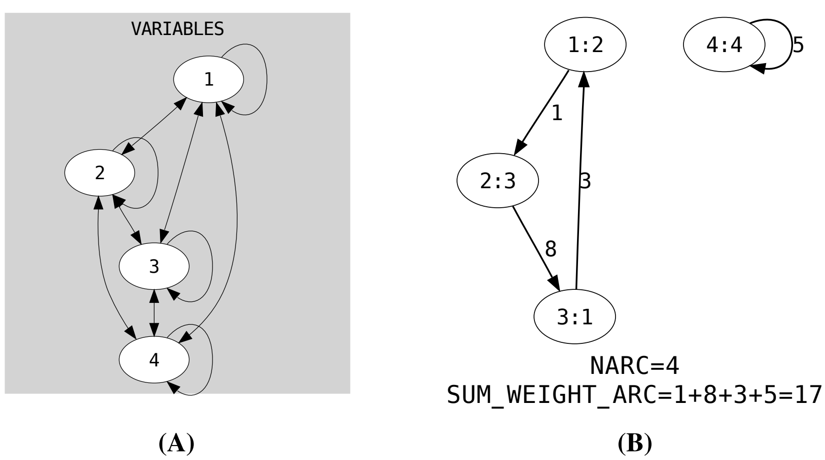

Figure 5.609: Initial and final graph of the MINIMUM_WEIGHT_ALLDIFFERENT constraint

Parts (A) and (B) of Figure 5.609 respectively show the initial and final graph associated with the **Example** slot. Since we use the **SUM_WEIGHT_ARC** graph property, the arcs of the final graph are stressed in bold. We also indicate their corresponding weights.

Constraint MULTI_GLOBAL_CONTIGUITY(VARIABLES)

Synonym MULTI_CONTIGUITY.

Argument VARIABLES : collection(var−dvar)

Restrictions required(VARIABLES, var)
VARIABLES.var ≥ 0

Purpose Enforce all variables of the VARIABLES collection to be assigned a value greater than or equal to 0. In addition, each value v strictly greater than 0 should appear contiguously.

Example $(\langle 0, 2, 2, 1, 1, 0, 0, 5\rangle)$

The MULTI_GLOBAL_CONTIGUITY constraint holds since the sequence 0 2 2 1 1 0 0 5 contains no more than one group of contiguous 1, no more than one group of contiguous 2, and no more than one group of contiguous 5.

Typical $|\text{VARIABLES}| > 3$

Typical model nval(VARIABLES.var) > 2
ATLEAST(2, VARIABLES, 0)

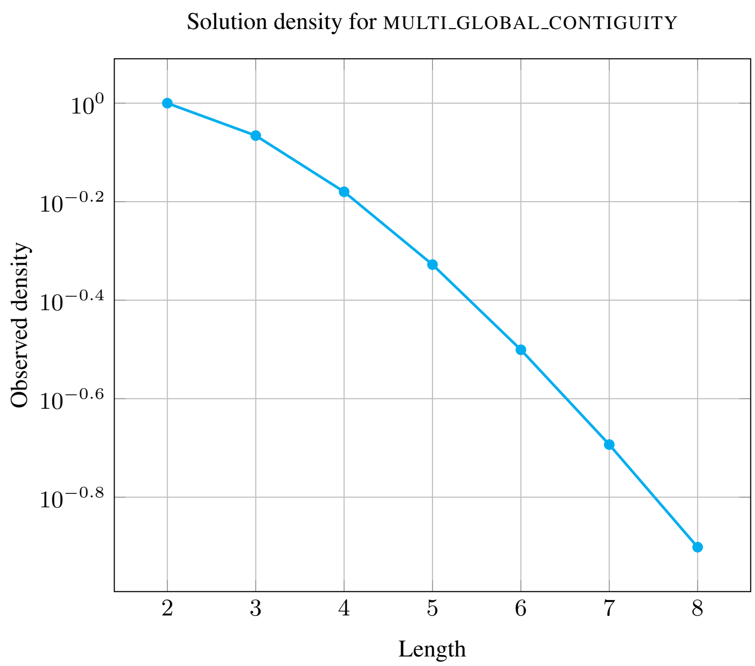
Symmetry Items of VARIABLES can be reversed.

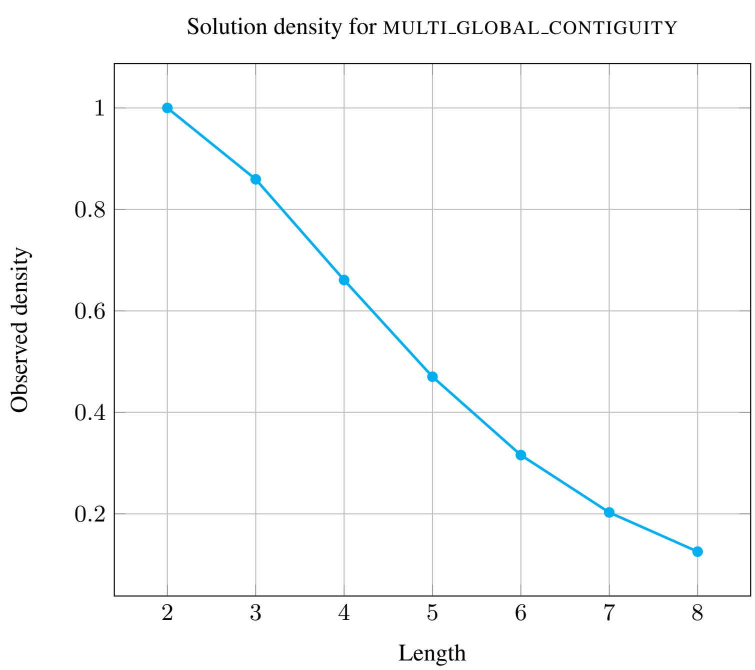
Arg. properties Contractible wrt. VARIABLES.

Counting

Length (n)	2	3	4	5	6	7	8
Solutions	9	55	413	3656	37147	425069	5400481

Number of solutions for MULTI_GLOBAL_CONTIGUITY: domains $0..n$





See also **common keyword:** GROUP *(sequence)*.

implied by: ALL_EQUAL, ALLDIFFERENT, ALLDIFFERENT_EXCEPT_0, DECREASING, GLOBAL_CONTIGUITY, INCREASING.

Keywords **combinatorial object:** sequence.
constraint type: predefined constraint.

5.273 MULTI_INTER_DISTANCE

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin [313]

Constraint MULTI_INTER_DISTANCE(VARIABLES, LIMIT, DIST)

Synonyms MULTI_ALL_MIN_DISTANCE, MULTI_ALL_MIN_DIST, SLIDING_ATMOST, ATMOST_SLIDING.

Arguments

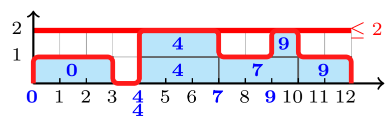
VARIABLES	:	collection(var−dvar)
LIMIT	:	int
DIST	:	int

Restrictions

required(VARIABLES, var)
LIMIT > 0
DIST > 0

Purpose Enforce that at most LIMIT variables of the collection VARIABLES are assigned values in any set consisting of DIST consecutive integer values.

Example $(\langle 4, 0, 9, 4, 7\rangle, 2, 3)$



The MULTI_INTER_DISTANCE constraint holds since, for each set of DIST $= 3$ consecutive values, no more than LIMIT $= 2$ variables of the VARIABLES collection $\langle 4, 0, 9, 4, 7\rangle$ are assigned a value from that set:

- At most two, in fact one, variables of the VARIABLES collection are assigned a value from the set $\{0, 1, 2\}$.
- At most two, in fact zero, variables of the VARIABLES collection are assigned a value from the set $\{1, 2, 3\}$.
- At most two, in fact two, variables of the VARIABLES collection are assigned a value from the set $\{2, 3, 4\}$.
- At most two, in fact two, variables of the VARIABLES collection are assigned a value from the set $\{3, 4, 5\}$.
- At most two, in fact two, variables of the VARIABLES collection are assigned a value from the set $\{4, 5, 6\}$.
- At most two, in fact one, variables of the VARIABLES collection are assigned a value from the set $\{5, 6, 7\}$.
- At most two, in fact one, variables of the VARIABLES collection are assigned a value from the set $\{6, 7, 8\}$.
- At most two, in fact two, variables of the VARIABLES collection are assigned a value from the set $\{7, 8, 9\}$.

Typical

LIMIT > 1
LIMIT $<$ |VARIABLES|
DIST > 1
DIST $<$range(VARIABLES.var)

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to the var attribute of all items of VARIABLES.
- LIMIT can be increased.
- MINDIST can be decreased to any value ≥ 1.

Arg. properties

Contractible wrt. VARIABLES.

Usage

The MULTI_INTER_DISTANCE constraint was tested for scheduling tasks that all have the same fixed duration in the context of air traffic management.

Algorithm

P. Ouellet and C.-G. Quimper came up with a cubic time complexity algorithm achieving bound-consistency in [313].

See also

generalisation: CUMULATIVE *(*line segment*, of same length, replaced by* line segment*)*.

specialisation: ALL_MIN_DIST *(*LIMIT *parameter set to* 1*)*, CARDINALITY_ATMOST *(window of* DIST *consecutive values replaced by window of size* 1*)*.

Keywords

application area: air traffic management.

constraint type: predefined constraint, value constraint, scheduling constraint.

filtering: bound-consistency.

modelling: at most.

5.274 MULTIPLE

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint MULTIPLE(X, Y, C)

Arguments

X : dvar
Y : dvar
C : int

Restrictions

$\mathtt{X} \neq 0$
$\mathtt{Y} \neq 0$
$\mathtt{C} > 0$

Purpose Enforce $\max(|\mathtt{X}|, |\mathtt{Y}|) = \mathtt{C} \cdot \min(|\mathtt{X}|, |\mathtt{Y}|)$, (with $|\mathtt{X}| \neq 0$ and $|\mathtt{Y}| \neq 0$).

Example $(8, -2, 4)$

The MULTIPLE constraint holds since $\max(|8|, |-2|) = 4 \cdot \min(|8|, |-2|)$.

Typical $\mathtt{C} > 1$

Arg. properties Functional dependency: C determined by X and Y.

Keywords

constraint arguments: binary constraint.
constraint type: predefined constraint, arithmetic constraint.
modelling: functional dependency.

5.275 NAND

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Logic

Constraint NAND(VAR, VARIABLES)

Synonym CLAUSE.

Arguments

VAR : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\texttt{VAR} \geq 0$
$\texttt{VAR} \leq 1$
$|\texttt{VARIABLES}| \geq 2$
required(VARIABLES, var)
$\texttt{VARIABLES.var} \geq 0$
$\texttt{VARIABLES.var} \leq 1$

Purpose Let VARIABLES be a collection of 0-1 variables $\texttt{VAR}_1, \texttt{VAR}_2, \ldots, \texttt{VAR}_n$ $(n \geq 2)$. Enforce $\texttt{VAR} = \neg(\texttt{VAR}_1 \wedge \texttt{VAR}_2 \wedge \cdots \wedge \texttt{VAR}_n)$.

Example

$(1, \langle 0, 0\rangle)$
$(1, \langle 0, 1\rangle)$
$(1, \langle 1, 0\rangle)$
$(0, \langle 1, 1\rangle)$
$(1, \langle 1, 0, 1\rangle)$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Functional dependency: VAR determined by VARIABLES.
- Contractible wrt. VARIABLES when $\texttt{VAR} = 0$.
- Extensible wrt. VARIABLES when $\texttt{VAR} = 1$.
- Aggregate: VAR($\vee$), VARIABLES(union).

Counting

Systems CLAUSE in **Choco**, CLAUSE in **Gecode**, #/\ in **SICStus**.

See also **common keyword:** AND, EQUIVALENT, IMPLY, NOR, OR, XOR *(Boolean constraint)*.

implies: ATLEAST_NVALUE.

Keywords **characteristic of a constraint:** automaton, automaton without counters, reified automaton constraint.

constraint arguments: pure functional dependency.

constraint network structure: Berge-acyclic constraint network.

constraint type: Boolean constraint.

filtering: arc-consistency.

modelling: functional dependency.

Cond. implications NAND(VAR, VARIABLES)
with $|\texttt{VARIABLES}| > 2$
implies SOME_EQUAL(VARIABLES).

Automaton Figure 5.610 depicts the automaton associated with the NAND constraint. To the first argument VAR of the NAND constraint corresponds the first signature variable. To each variable $\mathtt{VAR}_i$ of the second argument VARIABLES of the NAND constraint corresponds the next signature variable. There is no signature constraint.

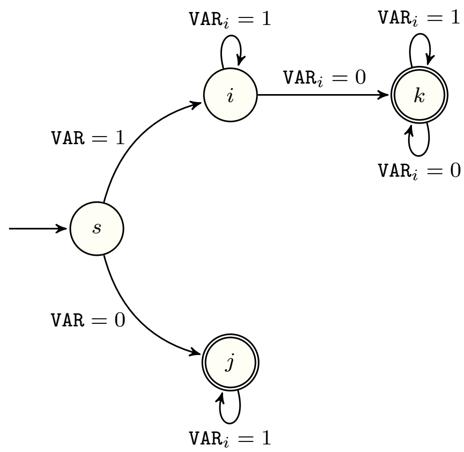

Figure 5.610: Automaton of the NAND constraint

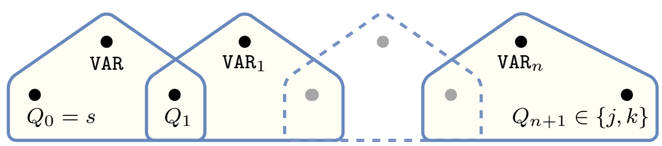

Figure 5.611: Hypergraph of the reformulation corresponding to the automaton of the NAND constraint

5.276 NCLASS

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from NVALUE.

Constraint NCLASS(NCLASS, VARIABLES, PARTITIONS)

Type VALUES : collection(val−int)

Arguments

NCLASS : dvar
VARIABLES : collection(var−dvar)
PARTITIONS : collection(p − VALUES)

Restrictions

|VALUES| ≥ 1
required(VALUES, val)
distinct(VALUES, val)
NCLASS ≥ 0
NCLASS $\leq$ min(|VARIABLES|, |PARTITIONS|)
NCLASS $\leq$range(VARIABLES.var)
required(VARIABLES, var)
required(PARTITIONS, p)
|PARTITIONS| ≥ 2

Purpose Number of partitions of the collection PARTITIONS such that at least one value is assigned to at least one variable of the collection VARIABLES.

Example $(2, \langle 3, 2, 7, 2, 6\rangle, \langle \mathtt{p} - \langle 1, 3\rangle, \mathtt{p} - \langle 4\rangle, \mathtt{p} - \langle 2, 6\rangle\rangle)$

Note that the values of $\langle 3, 2, 7, 2, 6\rangle$ occur within partitions p − $\langle 1, 3\rangle$ and p − $\langle 2, 6\rangle$ but not within p − $\langle 4\rangle$. Consequently, the NCLASS constraint holds since its first argument NCLASS is set to value 2.

Typical

NCLASS > 1
NCLASS $<$ |VARIABLES|
NCLASS $<$range(VARIABLES.var)
|VARIABLES| $>$ |PARTITIONS|

Symmetries

- Items of VARIABLES are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of VARIABLES.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.
- All occurrences of two distinct tuples of values in VARIABLES.var or PARTITIONS.p.val can be swapped; all occurrences of a tuple of values in VARIABLES.var or PARTITIONS.p.val can be renamed to any unused tuple of values.

Arg. properties

- Functional dependency: NCLASS determined by VARIABLES and PARTITIONS.
- Extensible wrt. VARIABLES when NCLASS $=$ |PARTITIONS|.

Algorithm

[29, 46].

See also

related: NEQUIVALENCE *(*variable $\in$ partition *replaced by* variable mod constant*)*, NINTERVAL *(*variable $\in$ partition *replaced by* variable/constant*)*, NPAIR *(*variable $\in$ partition *replaced by* pair *of* variables*)*.

specialisation: NVALUE *(*variable $\in$ partition *replaced by* variable*)*.

used in graph description: IN_SAME_PARTITION.

Keywords

characteristic of a constraint: partition.

constraint arguments: pure functional dependency.

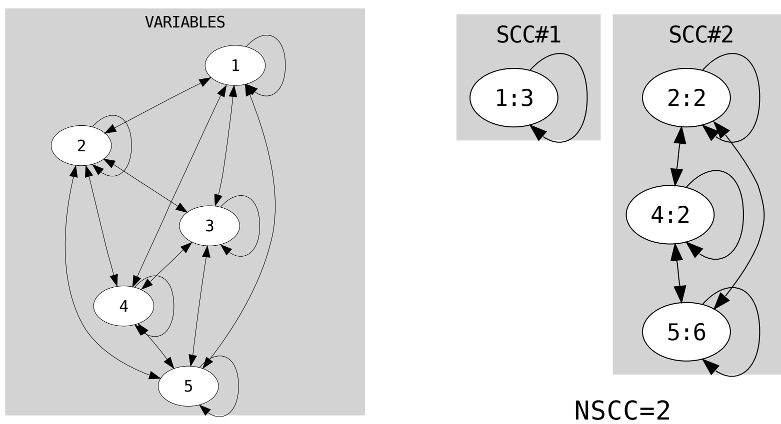
constraint type: counting constraint, value partitioning constraint.

final graph structure: strongly connected component, equivalence.

modelling: number of distinct equivalence classes, functional dependency.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	IN_SAME_PARTITION(variables1.var, variables2.var, PARTITIONS)
Graph property(ies)	**NSCC** = NCLASS

Graph model Parts (A) and (B) of Figure 5.612 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a class of values that was assigned to some variables of the VARIABLES collection. We effectively use two classes of values that respectively correspond to values $\{3\}$ and $\{2, 6\}$. Note that we do not consider value 7 since it does not belong to the different classes of values we gave: all corresponding arc constraints do not hold.



(A) **(B)**

Figure 5.612: Initial and final graph of the NCLASS constraint

5.277 NEQ

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint NEQ(VAR1, VAR2)

Synonym REL.

Arguments

VAR1	:	dvar
VAR2	:	dvar

Purpose Enforce the fact that two variables are not equal.

Example $(1, 8)$

The NEQ constraint holds since 1 is not equal to 8.

Symmetries

- Arguments are permutable w.r.t. permutation (VAR1, VAR2).
- A value in VAR1 or VAR2 can be renamed to any unused value.

Systems NEQ in **Choco**, REL in **Gecode**, #\= in **SICStus**.

See also

common keyword: GEQ, LEQ *(binary constraint,arithmetic constraint)*.

generalisation: NEQ_CST (constant *added*), NOT_ALL_EQUAL.

implied by: GT, LT.

negation: EQ.

system of constraints: ALLDIFFERENT.

Keywords

constraint arguments: binary constraint.

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

5.278 NEQ_CST

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint NEQ_CST(VAR1, VAR2, CST2)

Arguments

VAR1 : dvar
VAR2 : dvar
CST2 : int

Purpose Enforce the fact that the first variable is different from the sum of the second variable and the constant.

Example $(8, 2, 7)$

The NEQ_CST constraint holds since 8 is different from $2 + 7$.

Typical

$\mathtt{CST2} \neq 0$
$\mathtt{VAR1} \neq \mathtt{VAR2} + \mathtt{CST2}$

Symmetries

- Arguments are permutable w.r.t. permutation (VAR1) (VAR2, CST2).
- One and the same constant can be added to VAR1 and VAR2.
- One and the same constant can be added to VAR1 and CST2.

See also **negation:** EQ_CST.

specialisation: NEQ (constant *removed*).

Keywords **characteristic of a constraint:** disequality.

constraint arguments: binary constraint.

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

5.279 NEQUIVALENCE

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin

Derived from NVALUE.

Constraint

NEQUIVALENCE(NEQUIV, M, VARIABLES)

Arguments

NEQUIV	:	dvar
M	:	int
VARIABLES	:	collection(var−dvar)

Restrictions

required(VARIABLES, var)
NEQUIV $\geq$ min(1, |VARIABLES|)
NEQUIV $\leq$ min(M, |VARIABLES|)
NEQUIV $\leq$range(VARIABLES.var)
M > 0

Purpose

NEQUIV is the number of distinct rests obtained by dividing the variables of the collection VARIABLES by M.

Example

$(2, 3, \langle 3, 2, 5, 6, 15, 3, 3\rangle)$

Since the expressions $3 \bmod 3 = 0$, $2 \bmod 3 = 2$, $5 \bmod 3 = 2$, $6 \bmod 3 = 0$, $15 \bmod 3 = 0$, $3 \bmod 3 = 0$, and $3 \bmod 3 = 0$ involve two distinct values (values 0 and 2), the first argument NEQUIV of the NEQUIVALENCE constraint is set to value 2.

Typical

NEQUIV > 1
NEQUIV $<$ |VARIABLES|
NEQUIV $<$range(VARIABLES.var)
M > 1
M $<$maxval(VARIABLES.var)

Symmetries

- Items of VARIABLES are permutable.
- An occurrence of a value u of VARIABLES.var can be replaced by any other value v such that v is congruent to u modulo M.

Arg. properties

- Functional dependency: NEQUIV determined by M and VARIABLES.
- Contractible wrt. VARIABLES when NEQUIV $= 1$ and |VARIABLES| > 0.
- Contractible wrt. VARIABLES when NEQUIV $=$ |VARIABLES|.
- Extensible wrt. VARIABLES when NEQUIV $=$ M.

Algorithm

Since constraints $X = Y$ and $X \equiv Y \pmod{M}$ are similar, one should also use a similar algorithm as the one [29, 46] provided for constraint NVALUE.

See also

related: NCLASS *(*`variable` mod `constant` *replaced by* `variable` $\in$ `partition`*)*, NINTERVAL *(*`variable` mod `constant` *replaced by* `variable/constant`*)*, NPAIR *(*`variable` mod `constant` *replaced by* `pair` *of* `variables`*)*.

specialisation: NVALUE *(*`variable` mod `constant` *replaced by* `variable`*)*.

Keywords

constraint arguments: pure functional dependency.

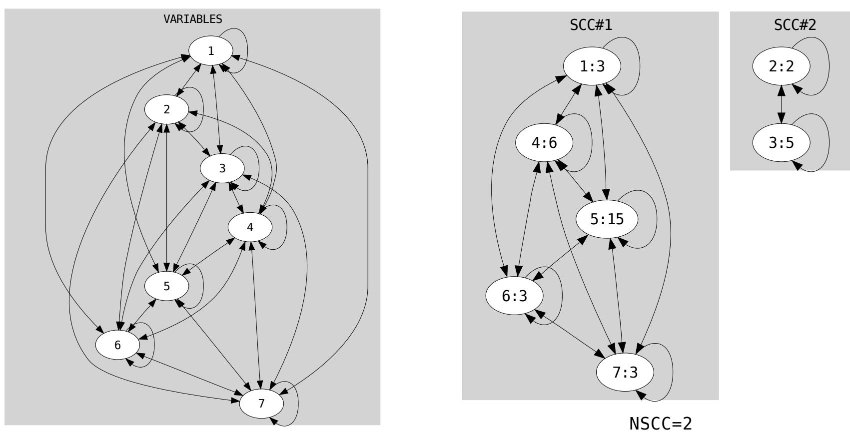
constraint type: counting constraint, value partitioning constraint.

final graph structure: strongly connected component, equivalence.

modelling: number of distinct equivalence classes, functional dependency.

Arc input(s)	`VARIABLES`
Arc generator	$CLIQUE \mapsto$ `collection`(`variables1`, `variables2`)
Arc arity	2
Arc constraint(s)	`variables1.var` mod `M` = `variables2.var` mod `M`
Graph property(ies)	**NSCC**= `NEQUIV`

Graph model Parts (A) and (B) of Figure 5.613 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to one equivalence class: We have two equivalence classes that respectively correspond to values $\{3, 6, 15\}$ and $\{2, 5\}$.



(A) **(B)**

Figure 5.613: Initial and final graph of the NEQUIVALENCE constraint

5.280 NEXT_ELEMENT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin N. Beldiceanu

Constraint NEXT_ELEMENT(THRESHOLD, INDEX, TABLE, VAL)

Arguments

THRESHOLD	:	dvar
INDEX	:	dvar
TABLE	:	collection(index−int, value−dvar)
VAL	:	dvar

Restrictions

INDEX ≥ 1
INDEX $\leq$ |TABLE|
THRESHOLD $<$ INDEX
required(TABLE, [index, value])
|TABLE| > 0
TABLE.index ≥ 1
TABLE.index $\leq$ |TABLE|
distinct(TABLE, index)

Purpose INDEX is the smallest entry of TABLE strictly greater than THRESHOLD containing value VAL.

Example

$$\left(2, 3, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{value}-1, \\ \texttt{index}-2 & \texttt{value}-8, \\ \texttt{index}-3 & \texttt{value}-9, \\ \texttt{index}-4 & \texttt{value}-5, \\ \texttt{index}-5 & \texttt{value}-9 \end{array} \right\rangle, 9\right)$$

The NEXT_ELEMENT constraint holds since 3 is the smallest entry located after entry 2 that contains value 9.

Typical

|TABLE| > 1
range(TABLE.value) > 1

Usage Originally introduced for modelling the fact that a nucleotide has to be consumed as soon as possible at cycle INDEX after a given cycle represented by variable THRESHOLD.

See also **related:** MINIMUM_GREATER_THAN *(identify an element in a table)*, NEXT_GREATER_ELEMENT *(allow to iterate over the values of a table)*.

Keywords **characteristic of a constraint:** minimum, automaton, automaton without counters, reified automaton constraint, derived collection.

constraint network structure: centered cyclic(3) constraint network(1).

constraint type: data constraint.

modelling: table.

Derived Collection	$\texttt{col}\left(\begin{array}{l}\texttt{ITEM}-\texttt{collection}(\texttt{index}-\texttt{dvar},\texttt{value}-\texttt{dvar}),\\ [\texttt{item}(\texttt{index}-\texttt{THRESHOLD},\texttt{value}-\texttt{VAL})]\end{array}\right)$
Arc input(s)	ITEM TABLE
Arc generator	$PRODUCT \mapsto$ collection(item, table)
Arc arity	2
Arc constraint(s)	• item.index < table.index • item.value = table.value
Graph property(ies)	**NARC** > 0
Sets	SUCC $\mapsto$ [source, variables − col(VARIABLES−collection(var−dvar), [item(var − TABLE.index)])]
Constraint(s) on sets	MINIMUM(INDEX, variables)

Graph model Parts (A) and (B) of Figure 5.614 respectively show the initial and final graph associated with the second graph constraint of the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

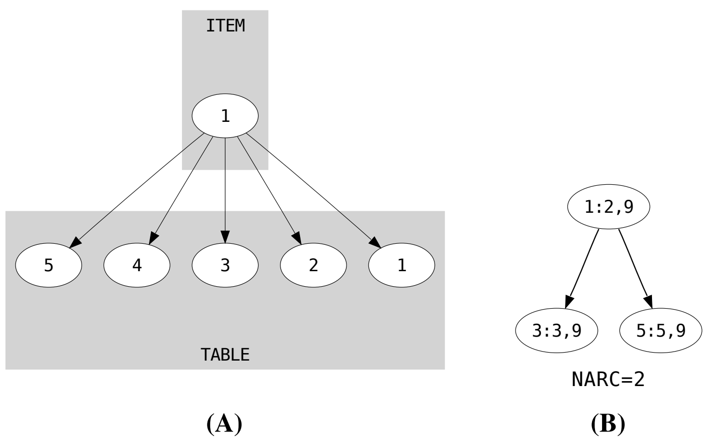


Figure 5.614: Initial and final graph of the NEXT_ELEMENT constraint

Automaton Figure 5.615 depicts the automaton associated with the NEXT_ELEMENT constraint. Let $\mathtt{I}_k$ and $\mathtt{V}_k$ respectively be the `index` and the `value` attributes of the k^{th} item of the `TABLE` collections. To each quintuple $(\mathtt{THRESHOLD}, \mathtt{INDEX}, \mathtt{VAL}, \mathtt{I}_k, \mathtt{V}_k)$ corresponds a signature variable S_k as well as the following signature constraint:

$$((\mathtt{I}_k \leq \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k < \mathtt{INDEX}) \wedge (\mathtt{V}_k = \mathtt{VAL})) \Leftrightarrow S_k = 0 \wedge$$
$$((\mathtt{I}_k \leq \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k < \mathtt{INDEX}) \wedge (\mathtt{V}_k \neq \mathtt{VAL})) \Leftrightarrow S_k = 1 \wedge$$
$$((\mathtt{I}_k \leq \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k = \mathtt{INDEX}) \wedge (\mathtt{V}_k = \mathtt{VAL})) \Leftrightarrow S_k = 2 \wedge$$
$$((\mathtt{I}_k \leq \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k = \mathtt{INDEX}) \wedge (\mathtt{V}_k \neq \mathtt{VAL})) \Leftrightarrow S_k = 3 \wedge$$
$$((\mathtt{I}_k \leq \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k > \mathtt{INDEX}) \wedge (\mathtt{V}_k = \mathtt{VAL})) \Leftrightarrow S_k = 4 \wedge$$
$$((\mathtt{I}_k \leq \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k > \mathtt{INDEX}) \wedge (\mathtt{V}_k \neq \mathtt{VAL})) \Leftrightarrow S_k = 5 \wedge$$
$$((\mathtt{I}_k > \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k < \mathtt{INDEX}) \wedge (\mathtt{V}_k = \mathtt{VAL})) \Leftrightarrow S_k = 6 \wedge$$
$$((\mathtt{I}_k > \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k < \mathtt{INDEX}) \wedge (\mathtt{V}_k \neq \mathtt{VAL})) \Leftrightarrow S_k = 7 \wedge$$
$$((\mathtt{I}_k > \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k = \mathtt{INDEX}) \wedge (\mathtt{V}_k = \mathtt{VAL})) \Leftrightarrow S_k = 8 \wedge$$
$$((\mathtt{I}_k > \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k = \mathtt{INDEX}) \wedge (\mathtt{V}_k \neq \mathtt{VAL})) \Leftrightarrow S_k = 9 \wedge$$
$$((\mathtt{I}_k > \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k > \mathtt{INDEX}) \wedge (\mathtt{V}_k = \mathtt{VAL})) \Leftrightarrow S_k = 10 \wedge$$
$$((\mathtt{I}_k > \mathtt{THRESHOLD}) \wedge (\mathtt{I}_k > \mathtt{INDEX}) \wedge (\mathtt{V}_k \neq \mathtt{VAL})) \Leftrightarrow S_k = 11.$$

The automaton is constructed in order to fulfil the following conditions:

- We look for an item of the `TABLE` collection such that $\mathtt{INDEX}_i > \mathtt{THRESHOLD}$ and $\mathtt{INDEX}_i = \mathtt{INDEX}$ and $\mathtt{VALUE}_i = \mathtt{VAL}$,
- There should not exist any item of the `TABLE` collection such that $\mathtt{INDEX}_i > \mathtt{THRESHOLD}$ and $\mathtt{INDEX}_i < \mathtt{INDEX}$ and $\mathtt{VALUE}_i = \mathtt{VAL}$.

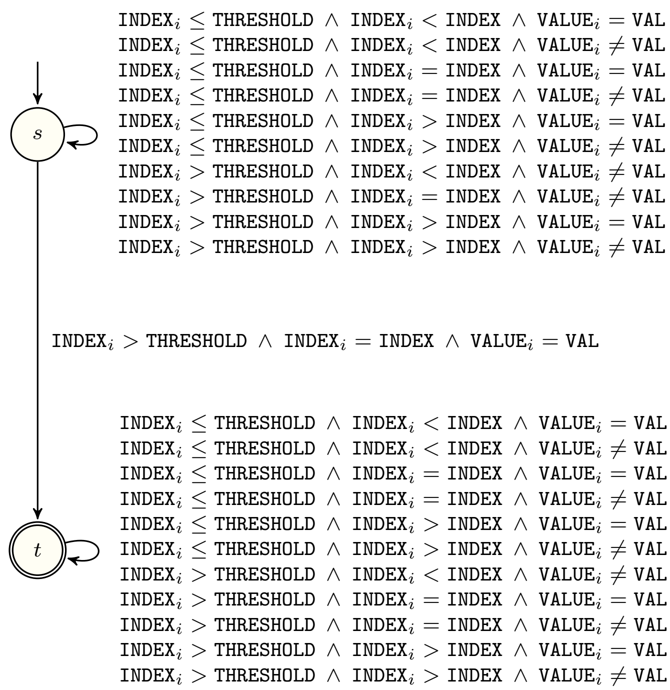

Figure 5.615: Automaton of the NEXT_ELEMENT constraint

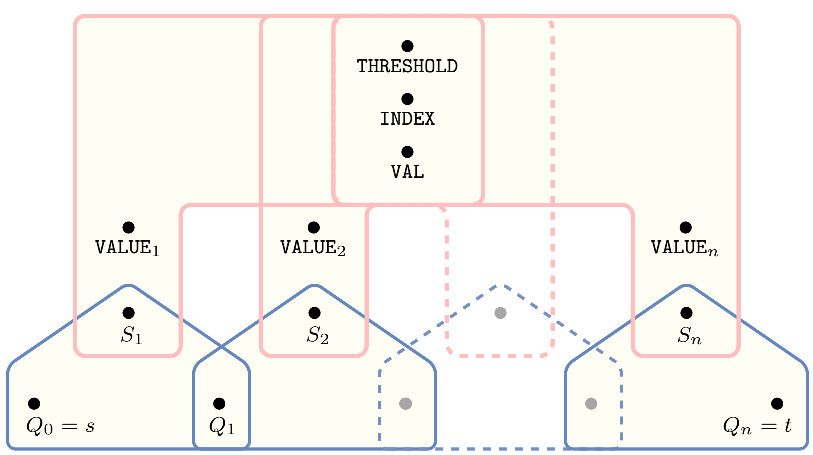

Figure 5.616: Hypergraph of the reformulation corresponding to the automaton of the NEXT_ELEMENT constraint

5.281 NEXT_GREATER_ELEMENT

DESCRIPTION LINKS GRAPH

Origin M. Carlsson

Constraint NEXT_GREATER_ELEMENT(VAR1, VAR2, VARIABLES)

Arguments

VAR1 : dvar
VAR2 : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\texttt{VAR1} < \texttt{VAR2}$
$|\texttt{VARIABLES}| > 0$
required(VARIABLES, var)

Purpose VAR2 is the value strictly greater than VAR1 located at the smallest possible entry of the table TABLE. In addition, the variables of the collection VARIABLES are sorted in strictly increasing order.

Example $(7, 8, \langle 3, 5, 8, 9\rangle)$

The NEXT_GREATER_ELEMENT constraint holds since:

- VAR2 is fixed to the first value 8 strictly greater than $\texttt{VAR1} = 7$,
- The var attributes of the items of the collection VARIABLES are sorted in strictly increasing order.

Typical

$|\texttt{VARIABLES}| > 1$
$\text{range}(\texttt{VARIABLES.var}) > 1$

Usage Originally introduced in [106] for modelling the fact that a nucleotide has to be consumed as soon as possible at cycle VAR2 after a given cycle VAR1.

Remark Similar to the MINIMUM_GREATER_THAN constraint, except for the fact that the var attributes are sorted.

Reformulation Let $V_1, V_2, \ldots, V_{|\texttt{VARIABLES}|}$ denote the variables of the collection of variables VARIABLES. By creating the extra variables M and $U_1, U_2, \ldots, U_{|\texttt{VARIABLES}|}$, the NEXT_GREATER_ELEMENT constraint can be expressed in term of the following constraints:

1. $V_1 < V_2 < \cdots < V_{|\texttt{VARIABLES}|}$
2. MAXIMUM(M, VARIABLES),
3. $\texttt{VAR2} > \texttt{VAR1}$,
4. $\texttt{VAR2} \leq M$,

5. $V_i \leq \texttt{VAR1} \Rightarrow U_i = M \;\; (i \in [1, |\texttt{VARIABLES}|])$,
6. $V_i > \texttt{VAR1} \Rightarrow U_i = V_i \;\; (i \in [1, |\texttt{VARIABLES}|])$,
7. MINIMUM$(\texttt{VAR2}, \langle U_1, U_2, \ldots, U_{|\texttt{VARIABLES}|}\rangle)$.

See also

common keyword: MINIMUM_GREATER_THAN *(order constraint)*.

implies: MINIMUM_GREATER_THAN.

related: NEXT_ELEMENT *(allow to iterate over the values of a table)*.

Keywords

characteristic of a constraint: minimum, derived collection.

constraint type: order constraint, data constraint.

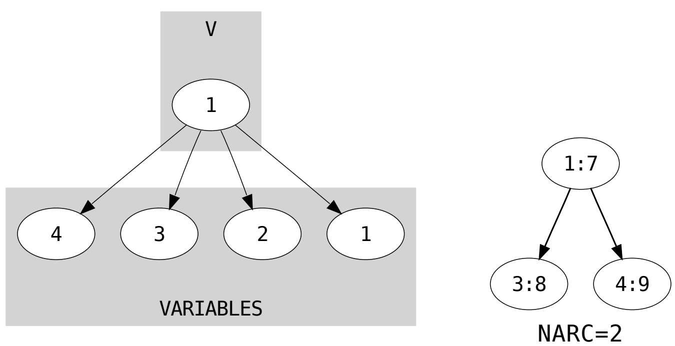
modelling: table.

Derived Collection	$\texttt{col}(\texttt{V}-\texttt{collection}(\texttt{var}-\texttt{dvar}), [\texttt{item}(\texttt{var}-\texttt{VAR1})])$

Arc input(s)	VARIABLES
Arc generator	$PATH \mapsto \texttt{collection}(\texttt{variables1}, \texttt{variables2})$
Arc arity	2
Arc constraint(s)	$\texttt{variables1.var} < \texttt{variables2.var}$
Graph property(ies)	$\mathbf{NARC} = \lvert\texttt{VARIABLES}\rvert - 1$

Arc input(s)	V VARIABLES
Arc generator	$PRODUCT \mapsto \texttt{collection}(\texttt{v}, \texttt{variables})$
Arc arity	2
Arc constraint(s)	$\texttt{v.var} < \texttt{variables.var}$
Graph property(ies)	$\mathbf{NARC} > 0$
Sets	$\mathsf{SUCC} \mapsto [\texttt{source}, \texttt{variables}]$
Constraint(s) on sets	$\textsc{minimum}(\texttt{VAR2}, \texttt{variables})$

Graph model Parts (A) and (B) of Figure 5.617 respectively show the initial and final graph associated with the second graph constraint of the **Example** slot. Since we use the $\mathbf{NARC}$ graph property, the arcs of the final graph are stressed in bold.



(A) **(B)**

Figure 5.617: Initial and final graph of the NEXT_GREATER_ELEMENT constraint

Signature Since the first graph constraint uses the $PATH$ arc generator on the VARIABLES collection, the number of arcs of the corresponding initial graph is equal to $\lvert\texttt{VARIABLES}\rvert - 1$. Therefore the maximum number of arcs of the final graph is equal to $\lvert\texttt{VARIABLES}\rvert - 1$. For this reason we can rewrite $\mathbf{NARC} = \lvert\texttt{VARIABLES}\rvert - 1$ to $\mathbf{NARC} \geq \lvert\texttt{VARIABLES}\rvert - 1$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.282 NINTERVAL

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from NVALUE.

Constraint NINTERVAL(NVAL, VARIABLES, SIZE_INTERVAL)

Arguments

NVAL	:	dvar
VARIABLES	:	collection(var−dvar)
SIZE_INTERVAL	:	int

Restrictions

NVAL $\geq$ min(1, |VARIABLES|)
NVAL $\leq$ |VARIABLES|
required(VARIABLES, var)
SIZE_INTERVAL > 0

Purpose Consider the intervals of the form [SIZE_INTERVAL $\cdot$ k, SIZE_INTERVAL $\cdot$ k + SIZE_INTERVAL − 1] where k is an integer. NVAL is the number of intervals for which at least one value is assigned to at least one variable of the collection VARIABLES.

Example $(2, \langle 3, 1, 9, 1, 9\rangle, 4)$

In the example, the third argument SIZE_INTERVAL $=$ 4 defines the following family of intervals $[4 \cdot k, 4 \cdot k + 3]$, where k is an integer. Values 3, 1, 9, 1 and 9 are respectively located within intervals $[0, 3]$, $[0, 3]$, $[8, 11]$, $[0, 3]$ and $[8, 11]$. Since we only use the two intervals $[0, 3]$ and $[8, 11]$ the first argument of the NINTERVAL constraint is set to value 2.

Typical

NVAL > 1
NVAL $<$ |VARIABLES|
SIZE_INTERVAL > 1
SIZE_INTERVAL $<$range(VARIABLES.var)
(nval(VARIABLES.var) + SIZE_INTERVAL − 1)/SIZE_INTERVAL $<$ NVAL

Symmetries

- Items of VARIABLES are permutable.
- An occurrence of a value of VARIABLES.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Arg. properties

- Functional dependency: NVAL determined by VARIABLES and SIZE_INTERVAL.
- Contractible wrt. VARIABLES when NVAL $= 1$ and |VARIABLES| > 0.
- Contractible wrt. VARIABLES when NVAL $=$ |VARIABLES|.

Usage The NINTERVAL constraint is useful for counting the number of actually used periods, no matter how many time each period is used. A period can, for example, stand for a hour or for a day.

Algorithm [29, 46].

See also **related:** NCLASS *(*`variable`/`constant` *replaced by* `variable` $\in$ `partition`*)*, NEQUIVALENCE *(*`variable`/`constant` *replaced by* `variable` mod `constant`*)*, NPAIR *(*`variable`/`constant` *replaced by* `pair` *of* `variables`*)*.

specialisation: NVALUE *(*`variable`/`constant` *replaced by* `variable`*)*.

Keywords **constraint arguments:** pure functional dependency.

constraint type: counting constraint, value partitioning constraint.

final graph structure: strongly connected component, equivalence.

modelling: number of distinct equivalence classes, interval, functional dependency.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var/SIZE_INTERVAL = variables2.var/SIZE_INTERVAL
Graph property(ies)	**NSCC** = NVAL

Graph model Parts (A) and (B) of Figure 5.618 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to those values of an interval that are assigned to some variables of the VARIABLES collection. The values 1, 3 and the value 9, which respectively correspond to intervals $[0, 3]$ and $[8, 11]$, are assigned to the variables of the VARIABLES collection.

5.283 NO_PEAK

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Derived from PEAK.

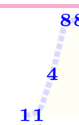
Constraint NO_PEAK(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restrictions |VARIABLES| > 0
required(VARIABLES, var)

Purpose A variable V_k $(1 < k < m)$ of the sequence of variables VARIABLES $= V_1, \dots, V_m$ is a *peak* if and only if there exists an i $(1 < i \leq k)$ such that $V_{i-1} < V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k > V_{k+1}$. The total number of peaks of the sequence of variables VARIABLES is equal to 0.

Example $(\langle 1, 1, 4, 8, 8 \rangle)$



The NO_PEAK constraint holds since the sequence 1 1 4 8 8 does not contain any peak.

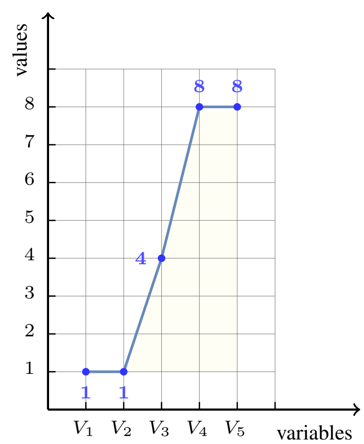


Figure 5.619: Illustration of the **Example** slot: a sequence of five variables V_1, V_2, V_3, V_4, V_5 respectively fixed to values 1, 1, 4, 8, 8 without any peak

Typical |VARIABLES| > 3
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Contractible wrt. VARIABLES.

Counting

Length (n)	2	3	4	5	6	7	8

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Derived from VALLEY.

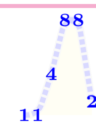
Constraint NO_VALLEY(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restrictions $|\text{VARIABLES}| > 0$
required(VARIABLES, var)

Purpose A variable V_k $(1 < k < m)$ of the sequence of variables VARIABLES $= V_1, \dots, V_m$ is a *valley* if and only if there exists an i $(1 < i \leq k)$ such that $V_{i-1} > V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k < V_{k+1}$. The total number of valleys of the sequence of variables VARIABLES is equal to 0.

Example $(\langle 1, 1, 4, 8, 8, 2\rangle)$



The NO_VALLEY constraint holds since the sequence 1 1 4 8 8 2 does not contain any valley.

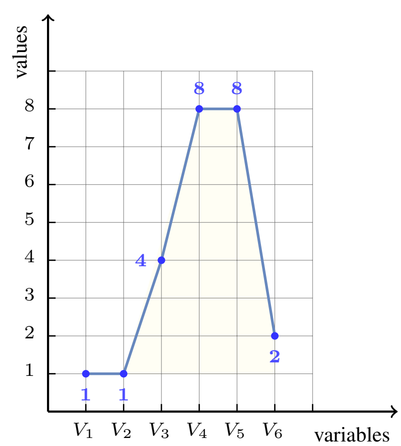


Figure 5.622: Illustration of the **Example** slot: a sequence of five variables V_1, V_2, V_3, V_4, V_5, V_6 respectively fixed to values 1, 1, 4, 8, 8, 2 without any valley

Typical $|\text{VARIABLES}| > 3$
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

5.285 NON_OVERLAP_SBOXES

DESCRIPTION LINKS LOGIC

Origin Geometry, derived from [42]

Constraint NON_OVERLAP_SBOXES(K, DIMS, OBJECTS, SBOXES)

Synonyms NON_OVERLAP, NON_OVERLAPPING.

Types

VARIABLES : collection(v−dvar)
INTEGERS : collection(v−int)
POSITIVES : collection(v−int)

Arguments

K : int
DIMS : sint
OBJECTS : collection(oid−int, sid−dvar, x − VARIABLES)
SBOXES : collection(sid−int, t − INTEGERS, l − POSITIVES)

Restrictions

$|\text{VARIABLES}| \geq 1$
$|\text{INTEGERS}| \geq 1$
$|\text{POSITIVES}| \geq 1$
required(VARIABLES, v)
$|\text{VARIABLES}| = \text{K}$
required(INTEGERS, v)
$|\text{INTEGERS}| = \text{K}$
required(POSITIVES, v)
$|\text{POSITIVES}| = \text{K}$
$\text{POSITIVES.v} > 0$
$\text{K} > 0$
$\text{DIMS} \geq 0$
$\text{DIMS} < \text{K}$
increasing_seq(OBJECTS, [oid])
required(OBJECTS, [oid, sid, x])
$\text{OBJECTS.oid} \geq 1$
$\text{OBJECTS.oid} \leq |\text{OBJECTS}|$
$\text{OBJECTS.sid} \geq 1$
$\text{OBJECTS.sid} \leq |\text{SBOXES}|$
required(SBOXES, [sid, t, l])
$\text{SBOXES.sid} \geq 1$
$\text{SBOXES.sid} \leq |\text{SBOXES}|$

Purpose

Holds if, for each pair of objects (O_i, O_j), $i < j$, O_i and O_j do not overlap with respect to a set of dimensions depicted by `DIMS`. O_i and O_j are objects that take a shape among a set of shapes. Each *shape* is defined as a finite set of shifted boxes, where each shifted box is described by a box in a `K`-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a *shifted box* is an entity defined by its shape id `sid`, shift offset `t`, and sizes `l`. Then, a shape is defined as the union of shifted boxes sharing the same shape id. An *object* is an entity defined by its unique object identifier `oid`, shape id `sid` and origin `x`.

An object O_i *does not overlap* an object O_j with respect to a set of dimensions depicted by `DIMS` if and only if, for all shifted box s_i associated with O_i and for all shifted box s_j associated with O_j, there exists a dimension $d \in$ `DIMS` such that the start of s_i in dimension d is greater than or equal to the end of s_j in dimension d, or the start of s_j in dimension d is greater than or equal to the end of s_i in dimension d.

Example

$$\left(\begin{array}{l} 2, \{0,1\}, \\ \left\langle\begin{array}{lll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 4,1\rangle, \\ \texttt{oid}-2 & \texttt{sid}-3 & \texttt{x}-\langle 2,2\rangle, \\ \texttt{oid}-3 & \texttt{sid}-4 & \texttt{x}-\langle 5,4\rangle \end{array}\right\rangle, \\ \left\langle\begin{array}{lll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-1 & \texttt{t}-\langle 1,0\rangle & \texttt{l}-\langle 1,3\rangle, \\ \texttt{sid}-1 & \texttt{t}-\langle 0,2\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 3,1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,1\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 2,1\rangle & \texttt{l}-\langle 1,1\rangle, \\ \texttt{sid}-3 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle, \\ \texttt{sid}-4 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,1\rangle \end{array}\right\rangle \end{array}\right)$$

Figure 5.625 shows the objects of the example. Since O_1 and O_2 do not overlap, since O_1 and O_3 do not overlap, and since O_2 and O_3 also do not overlap, the NON_OVERLAP_SBOXES constraint holds.

Typical

$|\texttt{OBJECTS}| > 1$

Symmetries

- Items of `OBJECTS` are permutable.
- Items of `SBOXES` are permutable.
- Items of `OBJECTS.x`, `SBOXES.t` and `SBOXES.l` are permutable (*same permutation used*).
- `SBOXES.l.v` can be decreased to any value ≥ 1.

Arg. properties

Suffix-contractible wrt. `OBJECTS`.

Remark

In addition from preventing objects to overlap, the DISJOINT_SBOXES constraint also enforces that borders and corners of objects are not directly in contact.

5.286 NOR

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Logic

Constraint NOR(VAR, VARIABLES)

Synonym CLAUSE.

Arguments

VAR : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\texttt{VAR} \geq 0$
$\texttt{VAR} \leq 1$
$|\texttt{VARIABLES}| \geq 2$
required(VARIABLES, var)
$\texttt{VARIABLES.var} \geq 0$
$\texttt{VARIABLES.var} \leq 1$

Purpose Let VARIABLES be a collection of 0-1 variables $\texttt{VAR}_1, \texttt{VAR}_2, \ldots, \texttt{VAR}_n$ $(n \geq 2)$. Enforce $\texttt{VAR} = \neg(\texttt{VAR}_1 \vee \texttt{VAR}_2 \vee \cdots \vee \texttt{VAR}_n)$.

Example

$(1, \langle 0, 0\rangle)$
$(0, \langle 0, 1\rangle)$
$(0, \langle 1, 0\rangle)$
$(0, \langle 1, 1\rangle)$
$(0, \langle 1, 0, 1\rangle)$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Functional dependency: VAR determined by VARIABLES.
- Contractible wrt. VARIABLES when $\texttt{VAR} = 1$.
- Extensible wrt. VARIABLES when $\texttt{VAR} = 0$.
- Aggregate: VAR($\wedge$), VARIABLES(union).

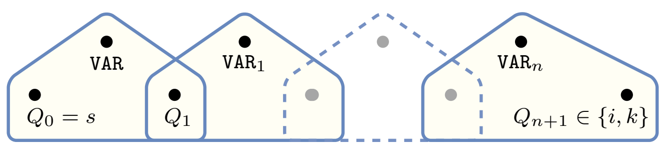

Figure 5.627: Hypergraph of the reformulation corresponding to the automaton of the NOR constraint

5.287 NOT_ALL_EQUAL

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin CHIP

Constraint NOT_ALL_EQUAL(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restrictions required(VARIABLES, var)
|VARIABLES| >1

Purpose The variables of the collection VARIABLES should take more than a single value.

Example $(\langle 3,1,3,3,3\rangle)$

The NOT_ALL_EQUAL constraint holds since the collection $\langle 3,1,3,3,3\rangle$ involves more than one value (i.e., values 1 and 3).

Typical |VARIABLES| >2
nval(VARIABLES.var) >2

Symmetries
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Extensible wrt. VARIABLES.

Algorithm If the intersection of the domains of the variables of the VARIABLES collection is empty the NOT_ALL_EQUAL constraint is entailed. Otherwise, when only a single variable V remains not fixed, remove the unique value (unique since the constraint is not entailed) taken by the other variables from the domain of V.

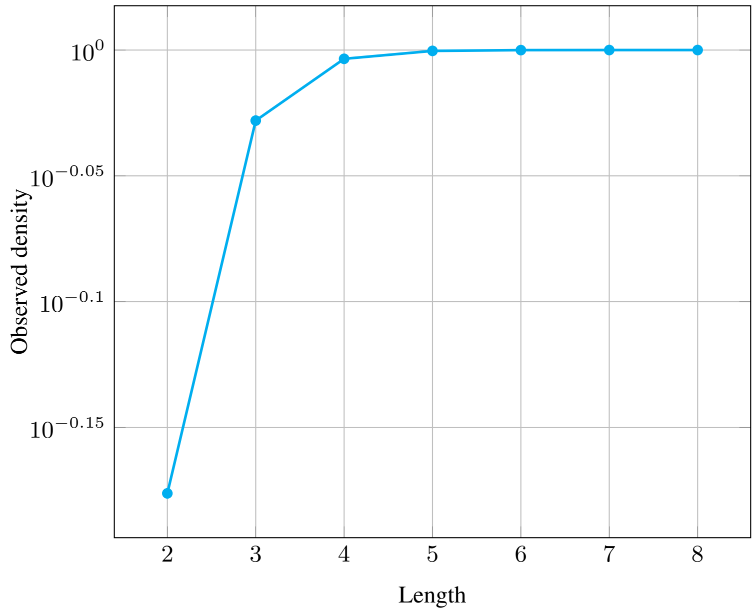
Reformulation The NOT_ALL_EQUAL(VARIABLES) constraint can be expressed as ATLEAST_NVALUE(2, VARIABLES).

Counting

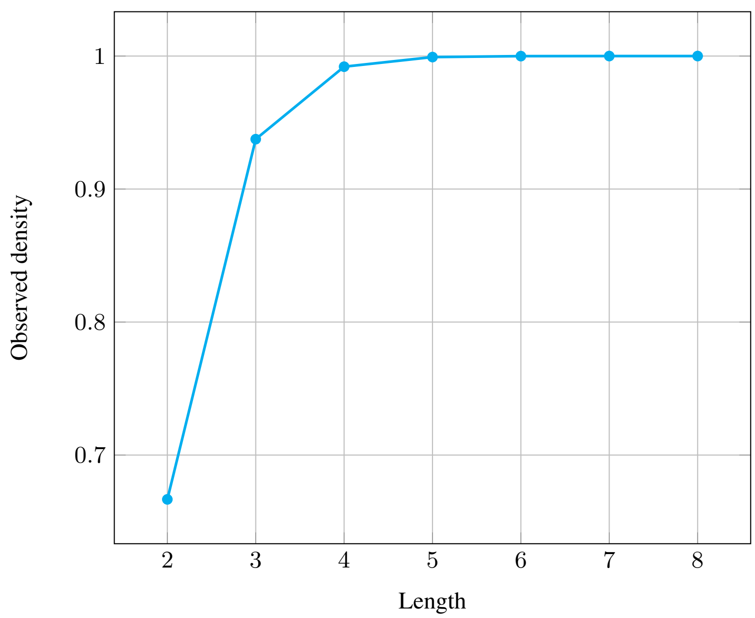
Length (n)	2	3	4	5	6	7	8
Solutions	6	60	620	7770	117642	2097144	43046712

Number of solutions for NOT_ALL_EQUAL: domains $0..n$

Solution density for NOT_ALL_EQUAL



Solution density for NOT_ALL_EQUAL



Systems REL in **Gecode**.

See also **generalisation:** NVALUE *(introduce a variable for counting the number of distinct values)*.

implied by: ALLDIFFERENT.

negation: ALL_EQUAL.

specialisation: NEQ *(when go down to two variables)*.

used in reformulation: ATLEAST_NVALUE.

Keywords

characteristic of a constraint: disequality, automaton, automaton without counters, reified automaton constraint.

constraint network structure: sliding cyclic(1) constraint network(1).

constraint type: value constraint.

filtering: arc-consistency.

final graph structure: equivalence.

Arc input(s)	VARIABLES
Arc generator	*CLIQUE*$\mapsto$collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NSCC**> 1

Graph model Parts (A) and (B) of Figure 5.628 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a value that is assigned to some variables of the VARIABLES collection. The NOT_ALL_EQUAL holds since the final graph contains more than one strongly connected component.

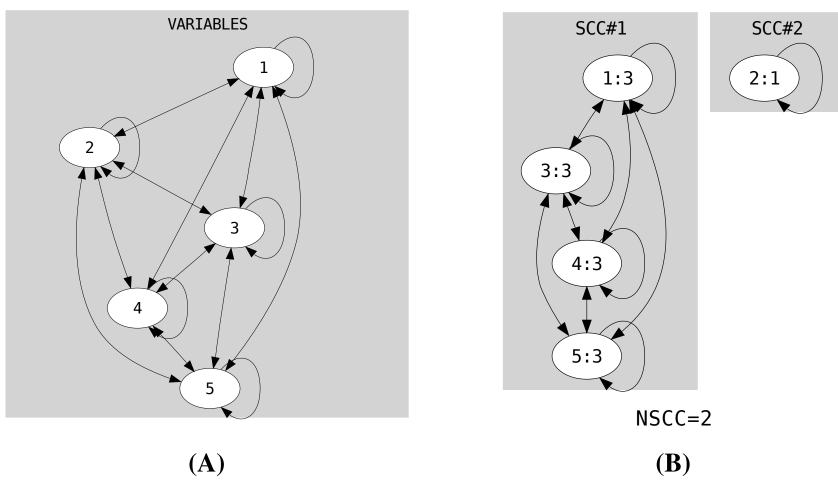


Figure 5.628: Initial and final graph of the NOT_ALL_EQUAL constraint

Automaton Figure 5.629 depicts the automaton associated with the NOT_ALL_EQUAL constraint. To each pair of consecutive variables $(\texttt{VAR}_i, \texttt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\texttt{VAR}_i$, $\texttt{VAR}_{i+1}$ and S_i: $\texttt{VAR}_i = \texttt{VAR}_{i+1} \Leftrightarrow S_i$.

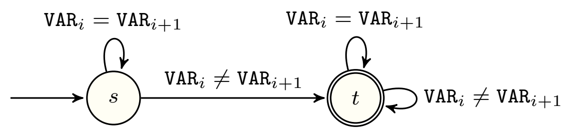

Figure 5.629: Automaton of the NOT_ALL_EQUAL constraint

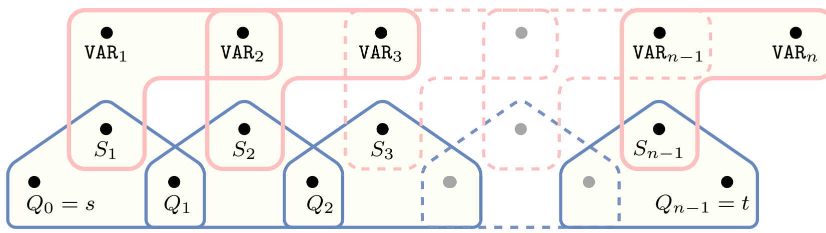

Figure 5.630: Hypergraph of the reformulation corresponding to the automaton of the NOT_ALL_EQUAL constraint

5.288 NOT_IN

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Derived from IN.

Constraint NOT_IN(VAR, VALUES)

Arguments

VAR : dvar
VALUES : collection(val−int)

Restrictions

required(VALUES, val)
distinct(VALUES, val)

Purpose Enforce VAR to be assigned a value different from the values of the VALUES collection.

Example $(2, \langle 1, 3\rangle)$

The constraint NOT_IN holds since the value of its first argument VAR $= 2$ does not occur within the collection $\langle 1, 3\rangle$.

Typical $|\text{VALUES}| > 1$

Symmetries

- Items of VALUES are permutable.
- One and the same constant can be added to VAR as well as to the val attribute of all items of VALUES.

Arg. properties Contractible wrt. VALUES.

Remark Entailment occurs immediately after posting this constraint and removing all values in VALUES from VAR.

Systems NOTMEMBER in **Choco**, REL in **Gecode**.

Used in GROUP.

See also **negation:** IN.

Keywords **characteristic of a constraint:** disequality, automaton, automaton without counters, reified automaton constraint, derived collection.

constraint arguments: unary constraint.

constraint network structure: centered cyclic(1) constraint network(1).

constraint type: value constraint.

filtering: arc-consistency, entailment.

modelling: excluded, domain definition.

Derived Collection $\texttt{col}(\texttt{VARIABLES}-\texttt{collection}(\texttt{var}-\texttt{dvar}), [\texttt{item}(\texttt{var}-\texttt{VAR})])$

Arc input(s) VARIABLES VALUES

Arc generator $PRODUCT \mapsto \texttt{collection}(\texttt{variables}, \texttt{values})$

Arc arity 2

Arc constraint(s) $\texttt{variables.var} = \texttt{values.val}$

Graph property(ies) $\mathbf{NARC} = 0$

Graph model Figure 5.631 shows the initial graph associated with the **Example** slot. Since we use the $\mathbf{NARC} = 0$ graph property the corresponding final graph is empty.

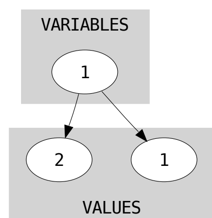

Figure 5.631: Initial graph of the NOT_IN constraint (the final graph is empty)

Signature Since 0 is the smallest number of arcs of the final graph we can rewrite $\mathbf{NARC} = 0$ to $\mathbf{NARC} \leq 0$. This leads to simplify $\overline{\underline{\mathbf{NARC}}}$ to $\underline{\mathbf{NARC}}$.

Automaton Figure 5.632 depicts the automaton associated with the NOT_IN constraint. Let $\texttt{VAL}_i$ be the val attribute of the i^{th} item of the VALUES collection. To each pair $(\texttt{VAR}, \texttt{VAL}_i)$ corresponds a 0-1 signature variable S_i as well as the following signature constraint: $\texttt{VAR} = \texttt{VAL}_i \Leftrightarrow S_i$.

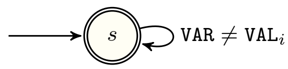

Figure 5.632: Automaton of the NOT_IN constraint

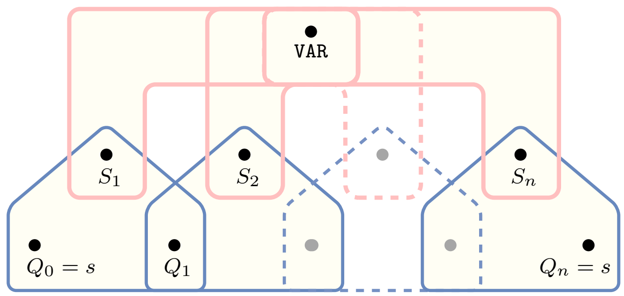

Figure 5.633: Hypergraph of the reformulation corresponding to the automaton of the NOT_IN constraint

5.289 NPAIR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin

Derived from NVALUE.

Constraint

NPAIR(NPAIRS, PAIRS)

Arguments

NPAIRS : dvar
PAIRS : collection(x−dvar, y−dvar)

Restrictions

$\texttt{NPAIRS} \geq \texttt{min}(1, |\texttt{PAIRS}|)$
$\texttt{NPAIRS} \leq |\texttt{PAIRS}|$
$\texttt{required}(\texttt{PAIRS}, [\texttt{x}, \texttt{y}])$

Purpose

NPAIRS is the number of distinct pairs of values assigned to the pairs of variables of the collection PAIRS.

Example

$$\left(2, \left\langle \begin{array}{ll} \texttt{x}-3 & \texttt{y}-1, \\ \texttt{x}-1 & \texttt{y}-5, \\ \texttt{x}-3 & \texttt{y}-1, \\ \texttt{x}-3 & \texttt{y}-1, \\ \texttt{x}-1 & \texttt{y}-5 \end{array} \right\rangle \right)$$

The NPAIR constraint holds since its first argument NPAIRS $= 2$ is set to the number of distinct pairs $\langle \texttt{x}-3\ \texttt{y}-1\rangle$ and $\langle \texttt{x}-1\ \texttt{y}-5\rangle$ of its second argument PAIRS.

Typical

$\texttt{NPAIRS} > 1$
$\texttt{NPAIRS} < |\texttt{PAIRS}|$
$|\texttt{PAIRS}| > 1$
$\texttt{range}(\texttt{PAIRS.x}) > 1$
$\texttt{range}(\texttt{PAIRS.y}) > 1$

Symmetries

- Items of PAIRS are permutable.
- Attributes of PAIRS are permutable w.r.t. permutation (x, y) (*permutation applied to all items*).
- All occurrences of two distinct tuples of values of NPAIRS can be swapped; all occurrences of a tuple of values of NPAIRS can be renamed to any unused tuple of values.

Arg. properties

- Functional dependency: NPAIRS determined by PAIRS.
- Contractible wrt. PAIRS when $\texttt{NPAIRS} = 1$ and $|\texttt{PAIRS}| > 0$.
- Contractible wrt. PAIRS when $\texttt{NPAIRS} = |\texttt{PAIRS}|$.

Remark

This is an example of a *number of distinct values* constraint where there is more than one attribute that is associated with each vertex of the final graph.

Arc constraint(s)	• pairs1.x = pairs2.x • pairs1.y = pairs2.y
Graph property(ies)	**NSCC** = NPAIRS

Graph model Parts (A) and (B) of Figure 5.634 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a pair of values that is assigned to some pairs of variables of the PAIRS collection. In our example we have the following pairs of values: $\langle$x − 3 y − 1$\rangle$ and $\langle$x − 1 y − 5$\rangle$.

5.290 NSET_OF_CONSECUTIVE_VALUES

DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint NSET_OF_CONSECUTIVE_VALUES(N, VARIABLES)

Arguments

N : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\mathtt{N} \geq 1$
$\mathtt{N} \leq |\mathtt{VARIABLES}|$
required(VARIABLES, var)

Purpose N is the number of set of consecutive values used by the variables of the collection VARIABLES.

Example

$(2, \langle 3, 1, 7, 1, 1, 2, 8\rangle)$
$(7, \langle 3, 1, 5, 7, 9, 11, 13\rangle)$
$(1, \langle 3, 3, 3, 3, 3, 3, 3\rangle)$

In the first example, the two parts $3, 1, 1, 1, 2$ and $7, 8$ take respectively their values in the following sets of consecutive values $\{1, 2, 3\}$ and $\{7, 8\}$. Consequently, the corresponding NSET_OF_CONSECUTIVE_VALUES constraint holds since its first argument $\mathtt{N} = 2$ is set to the number of sets of consecutive values.

Typical

$\mathtt{N} > 1$
$|\mathtt{VARIABLES}| > 1$
$\mathrm{range}(\mathtt{VARIABLES.var}) > 1$

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: N determined by VARIABLES.

Usage Used for specifying the fact that the values have to be used in a compact way is achieved by setting N to 1.

5.291 NUMBER_DIGIT

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint NUMBER_DIGIT(N, VARIABLES, B)

Arguments

N	:	dvar
VARIABLES	:	collection(var−dvar)
B	:	int

Restrictions

$\mathtt{N} \geq 0$
$|\mathtt{VARIABLES}| \geq 1$
$|\mathtt{VARIABLES}| \leq 9$
$\mathtt{VARIABLES.var} \geq 0$
$\mathtt{VARIABLES.var} \leq \mathtt{B} - 1$
$\mathtt{B} \geq 2$
$\mathtt{B} \leq 10$

Purpose Enforce N to be equal to the digits of VARIABLES in base B.

Example $(1234, \langle 1, 2, 3, 4 \rangle, 10)$

The NUMBER_DIGIT constraint holds since 1234 is equal to $1 \cdot 10^3 + 2 \cdot 10^2 + 3 \cdot 10 + 4$.

Arg. properties Functional dependency: N determined by VARIABLES and B.

Keywords **constraint arguments:** pure functional dependency.
constraint type: predefined constraint, arithmetic constraint.
modelling: functional dependency.

5.292 NVALUE

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin [314]

Constraint NVALUE(NVAL, VARIABLES)

Synonyms CARDINALITY_ON_ATTRIBUTES_VALUES, VALUES.

Arguments

NVAL	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

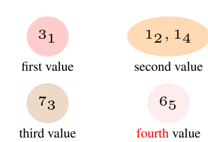
required(VARIABLES, var)
NVAL $\geq$ min(1, |VARIABLES|)
NVAL $\leq$ |VARIABLES|
NVAL $\leq$range(VARIABLES.var)

Purpose NVAL is the number of distinct values taken by the variables of the collection VARIABLES.

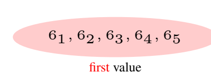
Example

$(4, \langle 3, 1, 7, 1, 6\rangle)$
$(1, \langle 6, 6, 6, 6, 6\rangle)$
$(5, \langle 6, 3, 0, 2, 9\rangle)$

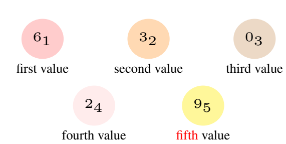
- The first NVALUE constraint holds since its first argument NVAL $=4$ is set to the number of distinct values occurring within the collection $\langle 3, 1, 7, 1, 6\rangle$.



- The second NVALUE constraint holds since its first argument NVAL $=1$ is set to the number of distinct values occurring within the collection $\langle 6, 6, 6, 6, 6\rangle$.



- The third NVALUE constraint holds since its first argument NVAL $=5$ is set to the number of distinct values occurring within the collection $\langle 6, 3, 0, 2, 9\rangle$.



All solutions Figure 5.636 gives all solutions to the following non ground instance of the NVALUE constraint: $\mathtt{N} \in [1, 2]$, $\mathtt{V}_1 \in [2, 4]$, $\mathtt{V}_2 \in [1, 2]$, $\mathtt{V}_3 \in [2, 4]$, NVALUE(N, $\langle \mathtt{V}_1, \mathtt{V}_2, \mathtt{V}_3\rangle$).

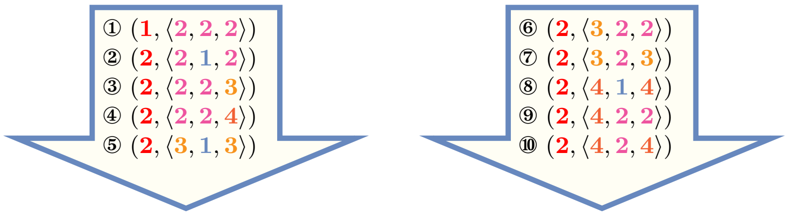


Figure 5.636: All solutions corresponding to the non ground example of the NVALUE constraint of the **All solutions** slot

Typical

`NVAL` > 1
`NVAL` $<$ |`VARIABLES`|
|`VARIABLES`| > 1

Symmetries

- Items of `VARIABLES` are permutable.
- All occurrences of two distinct values of `VARIABLES.var` can be swapped; all occurrences of a value of `VARIABLES.var` can be renamed to any unused value.

Arg. properties

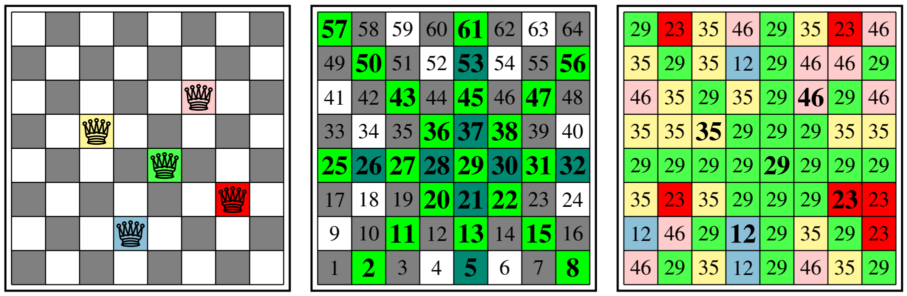
- Functional dependency: `NVAL` determined by `VARIABLES`.
- Contractible wrt. `VARIABLES` when `NVAL` $= 1$ and |`VARIABLES`| > 0.
- Contractible wrt. `VARIABLES` when `NVAL` $=$ |`VARIABLES`|.

Usage

The NVALUE constraint allows relaxing the ALLDIFFERENT constraint by restricting its first argument `NVAL` to be close, but not necessarily equal, to the number of variables of the `VARIABLES` collection.

A classical example from the early 1850s is the *dominating queens* chess puzzle problem: Place a number of queens on an n by n chessboard in such a way that all cells of the chessboard are either attacked by a queen or are occupied by a queen. A queen can attack all cells located on the same column, on the same row or on the same diagonal. Part (A) of Figure 5.637 illustrates a set of five queens which together attack all of the cells of an 8 by 8 chessboard. The *dominating queens* problem can be modelled by just one NVALUE constraint:

- We first label the different cells of the chessboard from 1 to n^2.
- We then associate to each cell c of the chessboard a domain variable. Its initial domain is set to the labels of the cells that can attack cell c. For instance, in the context of an 8 by 8 chessboard, the initial domain of V_{29} will be set to {2,5,8,11,13,15,20..22,25..32,36..38,43,45,47,50,53,56,57,61} (see the green cells of part (B) of Figure 5.637).
- Finally, we post the constraint NVALUE$(Q, \langle \mathtt{var} - V_1, \mathtt{var} - V_2, \ldots, \mathtt{var} - V_{n^2} \rangle)$ where Q is a domain variable in $[1, n^2]$ that gives the total number of queens used for controlling all cells of the chessboard. Note that variable Q should be passed to a minimisation procedure to get the smallest possible number of queens. For the solution depicted by Part (A) of Figure 5.637, the label in each cell of Part (C) of Figure 5.637 gives the value assigned to the corresponding variable. Note that,



(A) (B) (C)

Figure 5.637: Modelling the *dominating queens* problem with a single NVALUE constraint; (A) a solution to the dominating queens problem, (B) the initial domain (in bold) of the variable associated with cell 29: in a solution the value j assigned to the variable associated with cell i represents the label of the cell attacking cell i (i.e. in a solution one of the selected queens is located on cell j), (C) the value of each cell in the model with a single NVALUE constraint corresponding to the solution depicted in (A).

since a given cell can be attacked by several queens, we have also other assignments corresponding to the solution depicted by Part (A) of Figure 5.637.

To conclude note that, since we are only interested to restrict the maximum number of distinct values, we may replace the NVALUE constraint by the ATMOST_NVALUE constraint.

The NVALUE constraint occurs also in many practical applications. In the context of timetabling one wants to set up a limit on the maximum number of activity types it is possible to perform. For frequency allocation problems, one optimisation criterion is to minimise the number of distinct frequencies that you use all over the entire network.

The NVALUE constraint generalises several constraints like:

- ALLDIFFERENT(`VARIABLES`): in order to get the ALLDIFFERENT constraint, one has to set `NVAL` to the total number of variables.
- NOT_ALL_EQUAL(`VARIABLES`): in order to get the NOT_ALL_EQUAL constraint, one has to set the minimum value of `NVAL` to 2.
- ALL_EQUAL(`VARIABLES`): in order to get the ALL_EQUAL constraint, one has to set the maximum value of `NVAL` to 1.

Remark

This constraint appears in [314, page 339] under the name of *Cardinality on Attributes Values*. The NVALUE constraint is called VALUES in **JaCoP** (`http://www.jacop.eu/`). A constraint called K_DIFF enforcing that a set of variables takes at least k distinct values appears in the PhD thesis of J.-C. Régin [352].

It was shown in [75] that, finding out whether a NVALUE constraint has a solution or not is NP-hard. This was achieved by reduction from 3-SAT. In the same article, it is also shown, by reduction from minimum hitting set cardinality, that computing a sharp lower bound on `NVAL` is NP-hard.

Both reformulations of the COLOURED_CUMULATIVE constraint and of the COLOURED_CUMULATIVES constraint use the NVALUE constraint.

Algorithm A first filtering algorithm for the NVALUE constraint was described in [29]. Assuming that the minimum value of variable NVAL is not constrained at all, two algorithms that both achieve bound-consistency were provided one year later in [46]. Under the same assumption, algorithms that partially take into account holes in the domains of the variables of the VARIABLES collection are described in [46, 68].

Reformulation A model, involving linear inequalities constraints, preserving bound-consistency was introduced in [79].

Quiz

EXERCISE 1 (checking whether a ground instance holds or not)[a]

A. Does the constraint $\text{NVALUE}(0, \langle 0, 0, 0, 0\rangle)$ hold?

B. Does the constraint $\text{NVALUE}(3, \langle 1, 2, 3\rangle)$ hold?

C. Does the constraint $\text{NVALUE}(3, \langle 1, 2, 3, 3\rangle)$ hold?

[a] Hint: go back to the definition of NVALUE.

EXERCISE 2 (finding all solutions)[a]

Give all the solutions to the constraint:

$$\begin{cases} N \in \{1, 5\}, \\ V_1 \in [3, 5], \quad V_2 \in [3, 4], \quad V_3 \in [2, 5], \\ V_4 \in [3, 3], \quad V_5 \in [3, 4], \quad V_6 \in [3, 7], \\ \text{NVALUE}(N, \langle V_1, V_2, V_3, V_4, V_5, V_6\rangle). \end{cases}$$

[a] Hint: identify the smallest and largest possible values of N, enumerate solutions in lexicographic order.

EXERCISE 3 (identifying infeasible values wrt the at most side)[a]

Identify all variable-value pairs (V_i, val) $(1 \leq i \leq 6)$, such that the following constraint has no solution when variable V_i is assigned value val:

$$\begin{cases} N \in [0, 2], \\ V_1 \in [2, 4], \quad V_2 \in [2, 5], \quad V_3 \in [4, 5], \\ V_4 \in [4, 7], \quad V_5 \in [5, 8], \quad V_6 \in [6, 9], \\ \text{NVALUE}(N, \langle V_1, V_2, V_3, V_4, V_5, V_6\rangle). \end{cases}$$

[a] Hint: are variables equivalent wrt a given value?

EXERCISE 4 (identifying infeasible variable-value pairs wrt the at least side)[a]

Identify all variable-value pairs (V_i, val) $(1 \leq i \leq 6)$, such that the following constraint has no solution when variable V_i is assigned value val:

$$\begin{cases} N \in [5,6], \\ V_1 \in [2,4], \quad V_2 \in [2,3], \quad V_3 \in [4,5], \\ V_4 \in [2,3], \quad V_5 \in [2,3], \quad V_6 \in [5,6], \\ \text{NVALUE}(N, \langle V_1, V_2, V_3, V_4, V_5, V_6 \rangle). \end{cases}$$

[a]Hint: find out how to compute the maximum number of distinct values.

EXERCISE 5 (variable-based degree of violation)[a]

Compute the variable-based degree of violation[b] of the following constraints:

A. $\text{NVALUE}(4, \langle 2, 2, 2, 2 \rangle)$,

B. $\text{NVALUE}(3, \langle 3, 1, 5, 2, 3 \rangle)$.

[a]Hint: take advantage of the functional dependency.

[b]Given a constraint for which all variables are fixed, the *variable-based degree of violation* is the minimum number of variables to assign differently in order to satisfy the constraint.

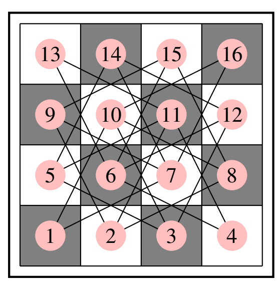
EXERCISE 6 (variations of dominating knights)[a]

A. Provide a model involving only one NVALUE constraint for showing that the cardinality of the dominating set[b] of the knight graph of a 4 by 4 chessboard does not exceed 4.

B. Show how to modify your model for also considering the fact that each knight must be protected by at least one other knight. Show that the number of required knights does not exceed 6.

[a]Hint: model the knight graph with a set of variables; in a domination problem whats matters for each vertex v is which vertices attack v.

[b]Given a graph G a *dominating set* $\mathcal{D}$ is a subset of the vertices of G such that every vertex of G either belongs to $\mathcal{D}$ or is adjacent to a vertex of G.



4×4 knight graph

SOLUTION TO EXERCISE 1

A. *No, since* $\langle 0,0,0,0\rangle$ *contains just one distinct value (and not* 0 *distinct values as stated by the first argument).*

B. *Yes, since* $\langle 1,2,3\rangle$ *contains* 3 *distinct values as stated by the first argument.*

C. *Yes, since* $\langle 1,2,3,3\rangle$ *contains* 3 *distinct values as stated by the the first argument.*

SOLUTION TO EXERCISE 2

the seven solutions

$N, \langle V_1, V_2, V_3, V_4, V_5, V_6\rangle$

① $(1, \langle 3,3,3,3,3,3\rangle)$
② $(5, \langle 5,3,2,3,4,6\rangle)$
③ $(5, \langle 5,3,2,3,4,7\rangle)$
④ $(5, \langle 5,4,2,3,3,6\rangle)$
⑤ $(5, \langle 5,4,2,3,3,7\rangle)$
⑥ $(5, \langle 5,4,2,3,4,6\rangle)$
⑦ $(5, \langle 5,4,2,3,4,7\rangle)$

A. *Value* 3 *being the only common value to variables* V_1, V_2, V_3, V_4, V_5, V_6, *we get a single solution where* N *is set to* 1, *i.e. solution ①.*

B. *A matching of cardinality* 5 *is given by* $V_1=5$, $V_2=3$, $V_3=2$, $V_4=3$, $V_5=4$, $V_6=6$. *It is maximum since variables* V_1, V_2, V_3, V_4, V_5 *have to be assigned one of the four values* 2, 3, 4 *and* 5, *and since values* 6 *and* 7 *can only be assigned to variable* V_6. *In any maximum matching we have that:*

(a) *Since variable* V_6 *is the only variable that can be assigned values* 6 *or* 7, *we have* $V_6=6$ *or* $V_6=7$.

(b) *Since variable* V_3 *is the only variable that can be assigned value* 2, *we have* $V_3=2$.

(c) *Now that* V_3 *is assigned value* 2 *and that* V_6 *is assigned values* 6 *or* 7, *variable* V_1 *is the only variable that can be assigned value* 5, *we have* $V_1=5$.

Finally combining the fact that variables V_2, V_5 *have to be assigned a distinct value in* $\{3,4\}$ *and variable* V_6 *a value in* $\{6,7\}$ *we obtain the remaining six solutions ②, ③, ④, ⑤, ⑥, ⑦.*

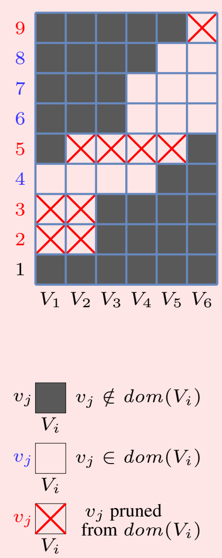
SOLUTION TO EXERCISE 3

The constraint forces that at most two distinct values are assigned to variables $V_1, V_2, \ldots, V_6$, i.e. there is no restriction coming from N on the minimum number of distinct values. In this context, a value val assigned to one of the variables V_i $(1 \leq i \leq 6)$ can be assigned to any other variable V_i without increasing the number of distinct values. Consequently a value val that is not removed (resp. removed) from a variable V_i $(1 \leq i \leq 6)$ can also not be removed (resp. removed) from a variable V_j $(j \neq i, 1 \leq j \leq 6)$. Let us successively study the values that can not be removed and the values that can be removed from $V_1, V_2, \ldots, V_6$.

A. [*FEASIBLE VALUES*]

Consider the three solutions
NVALUE$(2, \langle 4, 4, 4, 4, 6, 6\rangle)$,
NVALUE$(2, \langle 4, 4, 4, 4, 7, 7\rangle)$,
NVALUE$(2, \langle 4, 4, 4, 4, 8, 8\rangle)$.

All values used in the previous solutions (i.e., values 4, 6, 7, 8) can not be removed from $V_1, V_2, \ldots, V_6$.



B. [*INFEASIBLE VALUES*]

We now show that 2 cannot be assigned to any variable. If 2 can be used then we assign 2 to all variables that have 2 in their domains, i.e., V_1 and V_2. Now in order not to exceed two distinct values, the remaining variables V_3, V_4, V_5, V_6 must have a value in common, which is not the case. We can show in the same way that values 3, 5 and 9 cannot be assigned to any variable.

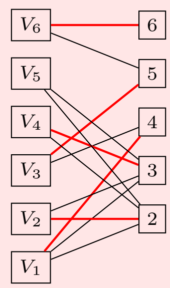
Finally since $V_1, V_2, \ldots, V_6$ do not have any value in common, N can only be equal to 2.

SOLUTION TO EXERCISE 4

The constraint forces that at least five distinct values are assigned to variables $V_1, V_2, \ldots, V_6$, i.e. there is no restriction coming from N on the maximum number of distinct values. Consequently identifying infeasible variable-value pairs is equivalent to finding edges that do not belong to any matching[a] *of cardinality greater than or equal to the minimum value of N in the variable-value bipartite graph $\mathcal{G}(V, E)$ associated with the* NVALUE *constraint (the vertices V of $\mathcal{G}$ are defined by the variables $V_1, V_2, \ldots, V_6$ and by the values $2, 3, \ldots, 6$, while the edges E are defined by the pairs (V_i, val), $(1 \leq i \leq 6)$ such that $val \in dom(V_i)$).*

A. [*MAXIMUM MATCHING*]

The solution nvalue$(5, \langle 4, 2, 5, 3, 2, 6\rangle)$ corresponds to a matching of cardinality 5 shown in red on the variable-value graph. This matching is maximum since $|dom(V_1) \cup dom(V_2) \cup \cdots \cup dom(V_6)| = 5$. Therefore N can only be equal to 5.

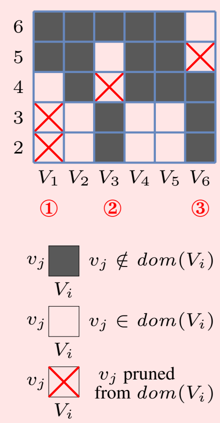


B. [*INFEASIBLE EDGES*]

① *Since $|dom(V_2) \cup dom(V_4)| = 2$, V_1 must be assigned value 4 in any maximum matching.*

② *Since V_1 must be assigned value 4 in any maximum matching and since $dom(V_3) = \{4, 5\}$, V_3 must be assigned value 5 in any maximum matching.*

③ *Since V_3 must be assigned value 5 in any maximum matching and since $dom(V_6) = \{5, 6\}$, V_6 must be assigned value 6 in any maximum matching.*



C. *Finally, V_2, V_4, V_5 must be assigned two distinct values from $\{2, 3\}$ in any maximum matching.*

---

[a] A *matching* of a graph $\mathcal{G}$ is a set of edges of $\mathcal{G}$ such that no two edges have a vertex in common.

SOLUTION TO EXERCISE 5

For a violated NVALUE *constraint it is always possible to change a single variable to get a feasible solution. This is done by setting the first argument of the* NVALUE *constraint to the number of distinct values occurring in the second argument.*

A. *The degree of violation is equal to* 1 *since the first argument needs to be set to* 1 *in order to obtain a solution.*

$$\text{NVALUE}(\overset{1}{\mathbf{4}}, \langle 2, 2, 2, 2\rangle)$$

B. *The degree of violation is equal to* 1 *since the first argument needs to be set to* 4 *in order to obtain a solution.*

$$\text{NVALUE}(\overset{4}{\mathbf{3}}, \langle 3, 1, 5, 2, 3\rangle)$$

Note that in this example we have other possibilities such as

$$\text{NVALUE}(3, \langle 3, 1, \overset{1}{\mathbf{5}}, 2, 3\rangle)$$

SOLUTION TO EXERCISE 6

A. *Each vertex of the* 4×4 *knight graph is represented by a variable whose domain is set to the labels of its adjacent vertices as well as to its own label. Consequently we get the following* 16 *variables with their corresponding initial domains:*

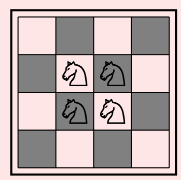
$V_1 \in \{1,7,10\}$, $V_2 \in \{2,8,9,11\}$, $V_3 \in \{3,5,10,12\}$,
$V_4 \in \{4,6,11\}$, $V_5 \in \{3,5,11,14\}$, $V_6 \in \{4,6,12,13,15\}$,
$V_7 \in \{1,7,9,14,16\}$, $V_8 \in \{2,8,10,15\}$, $V_9 \in \{2,7,9,15\}$,
$V_{10} \in \{1,3,8,10,16\}$, $V_{11} \in \{2,4,5,11,13\}$, $V_{12} \in \{3,6,12,14\}$,
$V_{13} \in \{6,11,13\}$, $V_{14} \in \{5,7,12,14\}$, $V_{15} \in \{6,8,9,15\}$,
$V_{16} \in \{7,10,16\}$.

We introduce a variable $N \in \{1,2,3,4\}$ *that provides the number of knights actually used and state the following constraint:*

$$\text{nvalue}(N, \langle V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}, V_{11}, V_{12}, V_{13}, V_{14}, V_{15}, V_{16} \rangle)$$

In the previous constraint the assignment $V_i = j$ *means that a knight is located on vertex* j *and that vertex* j *attacks vertex* i. *Consequently the total number of distinct values in* $\langle V_1, V_2, \ldots, V_{16} \rangle$ *is equal to the total number of used knights. The assignment*

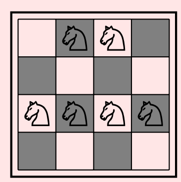
$N = 4$,
$V_1 = 7$, $V_2 = 11$, $V_3 = 10$, $V_4 = 6$,
$V_5 = 11$, $V_6 = 6$, $V_7 = 7$, $V_8 = 10$,
$V_9 = 7$, $V_{10} = 10$, $V_{11} = 11$, $V_{12} = 6$,
$V_{13} = 6$, $V_{14} = 7$, $V_{15} = 6$, $V_{16} = 7$



corresponds to the solution depicted on the right.

B. *Since a knight cannot protect itself, we only need to remove from the initial domain of each variable the label corresponding to its cell. The assignment*

$N = 6$,
$V_1 = 7$, $V_2 = 8$, $V_3 = 5$, $V_4 = 6$,
$V_5 = 14$, $V_6 = 15$, $V_7 = 14$, $V_8 = 15$,
$V_9 = 7$, $V_{10} = 8$, $V_{11} = 5$, $V_{12} = 6$,
$V_{13} = 6$, $V_{14} = 5$, $V_{15} = 6$, $V_{16} = 7$



corresponds to the solution depicted on the right.

5.293 NVALUE_ON_INTERSECTION

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from COMMON and NVALUE.

Constraint NVALUE_ON_INTERSECTION(NVAL, VARIABLES1, VARIABLES2)

Arguments

NVAL	:	dvar
VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)

Restrictions

required(VARIABLES1, var)
required(VARIABLES2, var)
NVAL ≥ 0
NVAL $\leq$ |VARIABLES1|
NVAL $\leq$ |VARIABLES2|
NVAL $\leq$range(VARIABLES1.var)
NVAL $\leq$range(VARIABLES2.var)

Purpose NVAL is the number of distinct values that both occur in the VARIABLES1 and VARIABLES2 collections.

Example $(2, \langle 1, 9, 1, 5 \rangle, \langle 2, 1, 9, 9, 6, 9 \rangle)$

Note that the two collections $\langle 1, 9, 1, 5 \rangle$ and $\langle 2, 1, 9, 9, 6, 9 \rangle$ share two values in common (i.e., values 1 and 9). Consequently the NVALUE_ON_INTERSECTION constraint holds since its first argument NVAL is set to 2.

Typical

NVAL > 0
NVAL $<$ |VARIABLES1|
NVAL $<$ |VARIABLES2|
NVAL $<$range(VARIABLES1.var)
NVAL $<$range(VARIABLES2.var)
|VARIABLES1| > 1
|VARIABLES2| > 1

Symmetries

- Arguments are permutable w.r.t. permutation (NVAL) (VARIABLES1, VARIABLES2).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Arg. properties

- Functional dependency: NVAL determined by VARIABLES1 and VARIABLES2.
- Contractible wrt. VARIABLES1 when NVAL $= 0$.
- Contractible wrt. VARIABLES2 when NVAL $= 0$.

5.294 NVALUES

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Inspired by NVALUE and COUNT.

Constraint NVALUES(VARIABLES, RELOP, LIMIT)

Arguments

VARIABLES : collection(var−dvar)
RELOP : atom
LIMIT : dvar

Restrictions

required(VARIABLES, var)
RELOP $\in [=, \neq, <, \geq, >, \leq]$

Purpose Let N be the number of distinct values assigned to the variables of the VARIABLES collection. Enforce condition N RELOP LIMIT to hold.

Example $(\langle 4, 5, 5, 4, 1, 5\rangle, =, 3)$

The NVALUES constraint holds since the number of distinct values occurring within the collection $\langle 4, 5, 5, 4, 1, 5\rangle$ is equal (i.e., RELOP is set to $=$) to its third argument LIMIT $= 3$.

Typical

$|$VARIABLES$| > 1$
LIMIT > 1
LIMIT $<$ $|$VARIABLES$|$
RELOP $\in [=, <, \geq, >, \leq]$

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties

- Contractible wrt. VARIABLES when RELOP $\in [<, \leq]$.
- Contractible wrt. VARIABLES when RELOP $\in [=]$, LIMIT $= 1$ and $|$VARIABLES$| > 0$.
- Contractible wrt. VARIABLES when RELOP $\in [=]$ and LIMIT $=$ $|$VARIABLES$|$.
- Extensible wrt. VARIABLES when RELOP $\in [\geq, >]$.

Usage Used in the **Constraint(s) on sets** slot for defining some constraints like ASSIGN_AND_NVALUES, CIRCUIT_CLUSTER or COLOURED_CUMULATIVE.

Reformulation The NVALUES(VARIABLES, RELOP , LIMIT) constraint can be expressed in term of the conjunction NVALUE(NV, VARIABLES) $\wedge$ NV RELOP LIMIT.

5.295 NVALUES_EXCEPT_0

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from NVALUES.

Constraint NVALUES_EXCEPT_0(VARIABLES, RELOP, LIMIT)

Arguments

VARIABLES	:	collection(var−dvar)
RELOP	:	atom
LIMIT	:	dvar

Restrictions

required(VARIABLES, var)
RELOP $\in [=, \neq, <, \geq, >, \leq]$

Purpose Let N be the number of distinct values, different from 0, assigned to the variables of the VARIABLES collection. Enforce condition N RELOP LIMIT to hold.

Example $(\langle 4, 5, 5, 4, 0, 1\rangle, =, 3)$

The NVALUES_EXCEPT_0 constraint holds since the number of distinct values, different from 0, occurring within the collection $\langle 4, 5, 5, 4, 0, 1\rangle$ is equal (i.e., RELOP is set to $=$) to its third argument LIMIT $= 3$.

Typical

$|\mathtt{VARIABLES}| > 1$
LIMIT > 1
LIMIT $< |\mathtt{VARIABLES}|$
ATLEAST(1, VARIABLES, 0)
RELOP $\in [=, <, \geq, >, \leq]$

Typical model ATLEAST(2, VARIABLES, 0)

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var that are both different from 0 can be swapped; all occurrences of a value of VARIABLES.var that is different from 0 can be renamed to any unused value that is also different from 0.

Arg. properties

- Contractible wrt. VARIABLES when RELOP $\in [<, \leq]$.
- Extensible wrt. VARIABLES when RELOP $\in [\geq, >]$.

Reformulation The NVALUES_EXCEPT_0($\langle V_1, V_2, \ldots, V_{|\mathtt{VARIABLES}|}\rangle$, RELOP , LIMIT) constraint can be expressed in term of the conjunction NVALUE($NV1$, $\langle 0, V_1, V_2, \ldots, V_{|\mathtt{VARIABLES}|}\rangle$) $\wedge$ $NV1 - 1$ RELOP LIMIT.

Used in CYCLE_OR_ACCESSIBILITY.

5.296 NVECTOR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Introduced by G. Chabert as a generalisation of NVALUE

Constraint NVECTOR(NVEC, VECTORS)

Synonyms NVECTORS, NPOINT, NPOINTS.

Type

VECTOR : collection(var−dvar)

Arguments

NVEC : dvar
VECTORS : collection(vec − VECTOR)

Restrictions

$|\text{VECTOR}| \geq 1$
$\text{NVEC} \geq \min(1, |\text{VECTORS}|)$
$\text{NVEC} \leq |\text{VECTORS}|$
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose

NVEC is the number of distinct tuples of values taken by the vectors of the collection VECTORS. Two tuples of values $\langle A_1, A_2, \ldots, A_m\rangle$ and $\langle B_1, B_2, \ldots, B_m\rangle$ are *distinct* if and only if there exist an integer $i \in [1, m]$ such that $A_i \neq B_i$.

Example

$$\left(2, \left\langle \begin{array}{l} \text{vec} - \langle 5,6\rangle, \\ \text{vec} - \langle 5,6\rangle, \\ \text{vec} - \langle 9,3\rangle, \\ \text{vec} - \langle 5,6\rangle, \\ \text{vec} - \langle 9,3\rangle \end{array} \right\rangle \right)$$

The NVECTOR constraint holds since its first argument NVEC = 2 is set to the number of distinct tuples of values (i.e., tuples $\langle 5, 6\rangle$ and $\langle 9, 3\rangle$) occurring within the collection VECTORS. Figure 5.643 depicts with a thick rectangle a possible initial domain for each of the five vectors and with a grey circle each tuple of values of the corresponding solution.

Typical

$|\text{VECTOR}| > 1$
$\text{NVEC} > 1$
$\text{NVEC} < |\text{VECTORS}|$
$|\text{VECTORS}| > 1$

Symmetries

- Items of VECTORS are permutable.
- Items of VECTORS.vec are permutable (*same permutation used*).
- All occurrences of two distinct tuples of values of VECTORS.vec can be swapped; all occurrences of a tuple of values of VECTORS.vec can be renamed to any unused tuple of values.

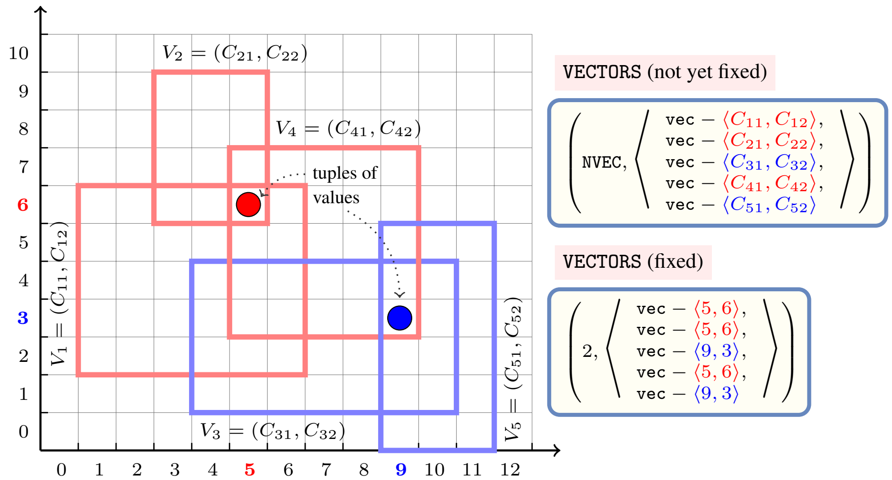

Figure 5.643: Possible initial domains ($C_{11} \in [1,6]$, $C_{12} \in [2,6]$, $C_{21} \in [3,5]$, $C_{22} \in [6,9]$, $C_{31} \in [4,10]$, $C_{32} \in [1,4]$, $C_{41} \in [5,9]$, $C_{42} \in [3,7]$, $C_{51} \in [9,11]$, $C_{52} \in [0,5]$) and solution corresponding to the **Example** slot: we have two distinct vectors (NVEC $= 2$)

Arg. properties

- Functional dependency: NVEC determined by VECTORS.
- Contractible wrt. VECTORS when NVEC $= 1$ and $|$VECTORS$| > 0$.
- Contractible wrt. VECTORS when NVEC $= |$VECTORS$|$.

Remark

It was shown in [118, 117] that, finding out whether a NVECTOR constraint has a solution or not is NP-hard (i.e., the restriction to the rectangle case and to the atmost side of the NVECTOR were considered for this purpose). This was achieved by reduction from the rectangle clique partition problem.

Reformulation

Assume the collection VECTORS is not empty (otherwise NVEC $= 0$). In this context, let n and m respectively denote the number of vectors of the collection VECTORS and the number of components of each vector. Furthermore, let $\alpha_i = \min(\underline{C_{1i}}, \underline{C_{2i}}, \ldots, \underline{C_{ni}})$, $\beta_i = \max(\overline{C_{1i}}, \overline{C_{2i}}, \ldots, \overline{C_{ni}})$, $\gamma_i = \beta_i - \alpha_i + 1$, $(i \in [1, m])$. By associating to each vector

$$\langle C_{k1}, C_{k2}, \ldots, C_{km}\rangle, \quad (k \in [1, n])$$

a variable

$$D_k = \sum_{1 \le i \le m} \left(\left(\prod_{i < j \le m} \gamma_j \right) \cdot (C_{ki} - \alpha_i) \right),$$

the constraint

NVECTOR(NVEC,
⟨vec − ⟨$C_{11}, C_{12}, \ldots, C_{1m}$⟩,
vec − ⟨$C_{21}, C_{22}, \ldots, C_{2m}$⟩,
....
vec − ⟨$C_{n1}, C_{n2}, \ldots, C_{nm}$⟩⟩)

can be expressed in term of the constraint
NVALUE(NVEC, $\langle D_1, D_2, \ldots, D_n\rangle$).

Note that the previous reformulation does not work anymore if the variables have a continuous domain, or if an overflow occurs while propagating the equality constraint $D_k = \sum_{1\leq i\leq m}\left(\left(\prod_{i<j\leq m}\gamma_j\right)\cdot(C_{ki}-\alpha_i)\right)$ (i.e., the number of components m is too big).

When using this reformulation with respect to the **Example** slot we first introduce $D_1 = 1\cdot 6-3+(4\cdot 5-20)) = 3$, $D_2 = 1\cdot 6-3+(4\cdot 5-20)) = 3$, $D_3 = 1\cdot 3-3+(4\cdot 9-20)) = 16$, $D_4 = 1\cdot 6-3+(4\cdot 5-20)) = 3$, $D_5 = 1\cdot 3-3+(4\cdot 9-20)) = 16$ and then get the constraint NVALUE$(2, \langle 3, 3, 16, 3, 16\rangle)$.

5.297 NVECTORS

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin

Inspired by NVECTOR and COUNT.

Constraint

NVECTORS(VECTORS, RELOP, LIMIT)

Synonym

NPOINTS.

Type

VECTOR : collection(var−dvar)

Arguments

VECTORS : collection(vec − VECTOR)
RELOP : atom
LIMIT : dvar

Restrictions

$|\text{VECTOR}| \geq 1$
required(VECTORS, vec)
same_size(VECTORS, vec)
$\text{RELOP} \in [=, \neq, <, \geq, >, \leq]$

Purpose

Let N be the number of distinct tuples of values taken by the vectors of the VECTORS collection. Enforce condition N RELOP LIMIT to hold.

Example

$$\left(\left\langle\begin{array}{l}\text{vec} - \langle 5,6\rangle,\\ \text{vec} - \langle 5,6\rangle,\\ \text{vec} - \langle 9,3\rangle,\\ \text{vec} - \langle 5,6\rangle,\\ \text{vec} - \langle 9,3\rangle\end{array}\right\rangle, =, 2\right)$$

The NVECTORS constraint holds since the number of distinct tuples of values (i.e., tuples $\langle 5,6\rangle$ and $\langle 9,3\rangle$) occurring within the collection VECTORS is equal (i.e., RELOP is set to $=$) to its third argument $\text{LIMIT} = 2$.

Typical

$|\text{VECTOR}| > 1$
$|\text{VECTORS}| > 1$
$\text{RELOP} \in [=, <, \geq, >, \leq]$
$\text{LIMIT} > 1$
$\text{LIMIT} < |\text{VECTORS}|$

Symmetries

- Items of VECTORS are permutable.
- Items of VECTORS.vec are permutable (*same permutation used*).
- All occurrences of two distinct values of VECTORS.vec can be swapped; all occurrences of a value of VECTORS.vec can be renamed to any unused value.

Arg. properties

- Contractible wrt. VECTORS when RELOP $\in [<, \leq]$.
- Extensible wrt. VECTORS when RELOP $\in [\geq, >]$.

Reformulation

The NVECTORS(VECTORS, RELOP , LIMIT) constraint can be expressed in term of the conjunction NVECTOR(NV, VECTORS) $\wedge$ NV RELOP LIMIT.

5.298 NVISIBLE_FROM_END

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Derived from NVISIBLE_FROM_START

Constraint NVISIBLE_FROM_END(N, VARIABLES)

Synonyms NVISIBLE, NVISIBLE_FROM_RIGHT.

Arguments

```
N         : dvar
VARIABLES : collection(var−dvar)
```

Restrictions

required(VARIABLES, var)
$\mathtt{N} \geq \mathtt{min}(1, |\mathtt{VARIABLES}|)$
$\mathtt{N} \leq |\mathtt{VARIABLES}|$

Purpose The i^{th} ($1 \leq i \leq |\mathtt{VARIABLES}|$) variable of the sequence VARIABLES is *visible* if and only if all variables after the i^{th} variable are strictly smaller than the i^{th} variable itself. N is the total number of visible variables of the sequence of variables VARIABLES.

Example

$(2, \langle 1, 6, 2, 1, 4, 8, 2\rangle)$
$(1, \langle 3, 6, 2, 1, 4, 8, 8\rangle)$
$(7, \langle 9, 8, 7, 5, 4, 3, 2\rangle)$

The first NVISIBLE_FROM_END constraint holds since the sequence 1 6 2 1 4 8 2 contains two visible items that respectively correspond to the seventh and sixth items.

Typical

$|\mathtt{VARIABLES}| > 2$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 2$

Typical model $\mathtt{nval}(\mathtt{VARIABLES.var}) > 2$

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: N determined by VARIABLES.

Arguments

```
N          : dvar
VARIABLES  : collection(var−dvar)
```

Restrictions

required(VARIABLES, var)
$\mathtt{N} \geq \mathtt{min}(1, |\mathtt{VARIABLES}|)$
$\mathtt{N} \leq |\mathtt{VARIABLES}|$

Purpose The i^{th} $(1 \leq i \leq |\mathtt{VARIABLES}|)$ variable of the sequence VARIABLES is *visible* if and only if all variables before the i^{th} variable are strictly smaller than the i^{th} variable itself. N is the total number of visible variables of the sequence of variables VARIABLES.

Example

$(3, \langle 1, 6, 2, 1, 4, 8, 2 \rangle)$
$(1, \langle 8, 6, 2, 1, 4, 8, 2 \rangle)$
$(7, \langle 0, 2, 3, 5, 6, 7, 9 \rangle)$

The first NVISIBLE_FROM_START constraint holds since the sequence 1 6 2 1 4 8 2 contains three visible items that respectively correspond to the first, second and sixth items.

Typical

$|\mathtt{VARIABLES}| > 2$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 2$

Typical model $\mathtt{nval}(\mathtt{VARIABLES.var}) > 2$

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: N determined by VARIABLES.

5.300 OPEN_ALLDIFFERENT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [438]

Constraint OPEN_ALLDIFFERENT(S, VARIABLES)

Synonyms OPEN_ALLDIFF, OPEN_ALLDISTINCT, OPEN_DISTINCT.

Arguments

S	:	svar
VARIABLES	:	collection(var−dvar)

Restrictions

$S \geq 1$
$S \leq |VARIABLES|$
required(VARIABLES, var)

Purpose Let $\mathcal{V}$ be the variables of the collection VARIABLES for which the corresponding position belongs to the set S. Positions are numbered from 1. Enforce all variables of $\mathcal{V}$ to take distinct values.

Example $(\{2, 3, 4\}, \langle 9, 1, 9, 3\rangle)$

The OPEN_ALLDIFFERENT constraint holds since the last three (i.e., $S = \{2, 3, 4\}$) values of the collection $\langle 9, 1, 9, 3\rangle$ are distinct.

Typical $|VARIABLES| > 2$

Symmetry All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Suffix-contractible wrt. VARIABLES.

Usage In their article [438], W.-J. van Hoeve and J.-C. Régin motivate the OPEN_ALLDIFFERENT constraint by the following scheduling problem. Consider a set of activities (where each activity has a fixed duration 1 and a start variable) that can be processed on two factory lines such that all the activities that will be processed on a given line must be pairwise distinct. This can be modelled by using one OPEN_ALLDIFFERENT constraint for each line, involving all the start variables as well as a set variable whose final value specifies the set of activities assigned to that specific factory line.

Note that this can also be directly modelled by a single DIFFN constraint. This is done by introducing an assignment variable for each activity. The initial domain of each assignment variable consists of two values that respectively correspond to the two factory lines.

Algorithm A slight adaptation of the flow model that handles the original GLOBAL_CARDINALITY constraint [353] is described in [438]. The rightmost part of Figure 3.29 illustrates this flow model.

filtering: flow.

[14] An *active value* corresponds to a value occuring at a position mentionned in the set S.

Arc input(s) VARIABLES

Arc generator $CLIQUE \mapsto$ collection(variables1, variables2)

Arc arity 2

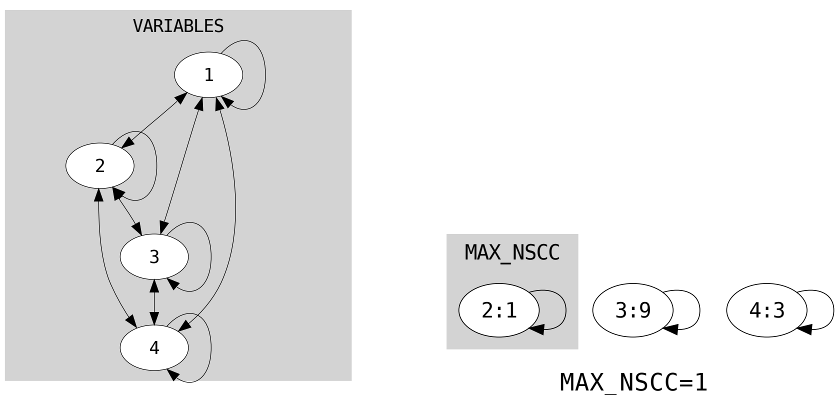
Arc constraint(s)
- variables1.var = variables2.var
- IN_SET(variables1.key, S)
- IN_SET(variables2.key, S)

Graph property(ies) **MAX_NSCC** ≤ 1

Graph class ONE_SUCC

Graph model We generate a *clique* with an *equality* constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed one. Variables for which the corresponding position does not belong to the set S are removed from the final graph by the second and third conditions of the arc-constraint.

Parts (A) and (B) of Figure 5.650 respectively show the initial and final graph associated with the **Example** slot. Since we use the **MAX_NSCC** graph property we show one of the largest strongly connected components of the final graph. The OPEN_ALLDIFFERENT holds since all the strongly connected components have at most one vertex: a value is used at most once.



(A) **(B)**

Figure 5.650: Initial and final graph of the OPEN_ALLDIFFERENT constraint

5.301 OPEN_AMONG

DESCRIPTION LINKS GRAPH

Origin

Derived from AMONG and OPEN_GLOBAL_CARDINALITY.

Constraint

OPEN_AMONG(S, NVAR, VARIABLES, VALUES)

Arguments

S	:	svar
NVAR	:	dvar
VARIABLES	:	collection(var−dvar)
VALUES	:	collection(val−int)

Restrictions

$\mathtt{S} \geq 1$
$\mathtt{S} \leq |\mathtt{VARIABLES}|$
$\mathtt{NVAR} \geq 0$
$\mathtt{NVAR} \leq |\mathtt{VARIABLES}|$
required(VARIABLES, var)
required(VALUES, val)
distinct(VALUES, val)

Purpose

Let $\mathcal{V}$ be the variables of the collection VARIABLES for which the corresponding position belongs to the set S. Positions are numbered from 1. NVAR is the number of variables of $\mathcal{V}$ that take their values in VALUES.

Example

$(\{2,3,4,5\}, 3, \langle 8,5,5,4,1\rangle, \langle 1,5,8\rangle)$

The OPEN_AMONG constraint holds since within the last four values (i.e., $\mathtt{S} = \{2,3,4,5\}$) of $\langle 8,5,5,4,1\rangle$ exactly 3 values belong to the set of values $\{1,5,8\}$.

Typical

$\mathtt{NVAR} > 0$
$\mathtt{NVAR} < |\mathtt{VARIABLES}|$
$|\mathtt{VARIABLES}| > 1$
$|\mathtt{VALUES}| > 1$
$|\mathtt{VARIABLES}| > |\mathtt{VALUES}|$

Symmetries

- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

Arg. properties

- Functional dependency: NVAR determined by S, VARIABLES and VALUES.
- Suffix-contractible wrt. VARIABLES when $\mathtt{NVAR} = 0$.

See also

common keyword: OPEN_ATLEAST, OPEN_ATMOST *(open constraint,value constraint)*, OPEN_GLOBAL_CARDINALITY *(open constraint,counting constraint)*.

hard version: AMONG.

used in graph description: IN_SET.

Keywords

constraint arguments: constraint involving set variables.

constraint type: open constraint, value constraint, counting constraint.

modelling: functional dependency.

Arc input(s)	VARIABLES
Arc generator	$SELF$ ↦ collection(variables)
Arc arity	1
Arc constraint(s)	• IN(variables.var, VALUES) • IN_SET(variables.key, S)
Graph property(ies)	**NARC** = NVAR

Graph model The arc constraint corresponds to the conjunction of unary constraints IN(variables.var, VALUES) and IN_SET(variables.key, S) defined in this catalogue. Consequently we employ the $SELF$ arc generator in order to produce an initial graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.651 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the loops of the final graph are stressed in bold.

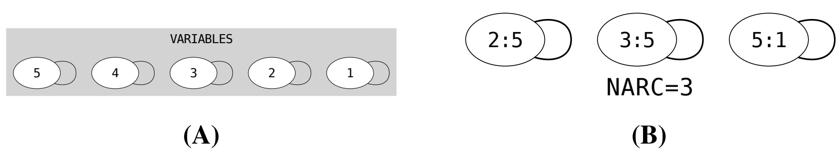


Figure 5.651: Initial and final graph of the OPEN_AMONG constraint

5.302 OPEN_ATLEAST

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from ATLEAST and OPEN_GLOBAL_CARDINALITY.

Constraint OPEN_ATLEAST(S, N, VARIABLES, VALUE)

Arguments

S	:	svar
N	:	int
VARIABLES	:	collection(var−dvar)
VALUE	:	int

Restrictions

$\mathtt{S} \geq 1$
$\mathtt{S} \leq |\mathtt{VARIABLES}|$
$\mathtt{N} \geq 0$
$\mathtt{N} \leq |\mathtt{VARIABLES}|$
required(VARIABLES, var)

Purpose Let $\mathcal{V}$ be the variables of the collection VARIABLES for which the corresponding position belongs to the set S. Positions are numbered from 1. At least N variables of $\mathcal{V}$ are assigned value VALUE.

Example $(\{2,3,4\}, 2, \langle 4,2,4,4\rangle, 4)$

The OPEN_ATLEAST constraint holds since, within the last three (i.e., $\mathtt{S} = \{2,3,4\}$) values of the collection $\langle 4,2,4,4\rangle$, at least $\mathtt{N} = 2$ values are equal to value $\mathtt{VALUE} = 4$.

Typical

$\mathtt{N} > 0$
$\mathtt{N} < |\mathtt{VARIABLES}|$
$|\mathtt{VARIABLES}| > 1$

Symmetries

- N can be decreased to any value ≥ 0.
- An occurrence of a value of VARIABLES.var that is different from VALUE can be replaced by any other value.

Arg. properties Suffix-extensible wrt. VARIABLES.

See also **common keyword:** OPEN_AMONG, OPEN_GLOBAL_CARDINALITY *(open constraint,value constraint)*.

comparison swapped: OPEN_ATMOST.

hard version: ATLEAST.

used in graph description: IN_SET.

Keywords **constraint arguments:** constraint involving set variables.

constraint type: open constraint, value constraint.

modelling: at least.

Arc input(s)	VARIABLES
Arc generator	*SELF* ↦ collection(variables)
Arc arity	1
Arc constraint(s)	• variables.var = VALUE • IN_SET(variables.key, S)
Graph property(ies)	**NARC** ≥ N

Graph model Since each arc constraint involves only one vertex (VALUE is fixed), we employ the *SELF* arc generator in order to produce a graph with a single loop on each vertex. Variables for which the corresponding position does not belong to the set S are removed from the final graph by the second condition of the arc-constraint.

Parts (A) and (B) of Figure 5.652 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the loops of the final graph are stressed in bold.

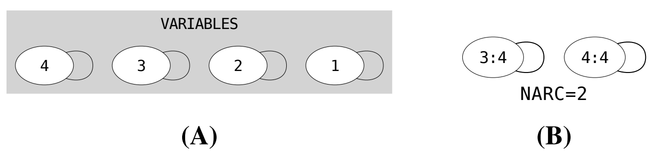

Figure 5.652: Initial and final graph of the OPEN_ATLEAST constraint

5.303 OPEN_ATMOST

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from ATMOST and OPEN_GLOBAL_CARDINALITY.

Constraint OPEN_ATMOST(S, N, VARIABLES, VALUE)

Arguments

S	:	svar
N	:	int
VARIABLES	:	collection(var−dvar)
VALUE	:	int

Restrictions

$\mathtt{S} \geq 1$
$\mathtt{S} \leq |\mathtt{VARIABLES}|$
$\mathtt{N} \geq 0$
required(VARIABLES, var)

Purpose Let $\mathcal{V}$ be the variables of the collection VARIABLES for which the corresponding position belongs to the set S. Positions are numbered from 1. At most N variables of $\mathcal{V}$ are assigned value VALUE.

Example $(\{2, 3, 4\}, 1, \langle 2, 2, 4, 5\rangle, 2)$

The OPEN_ATMOST constraint holds since, within the last three (i.e., $\mathtt{S} = \{2, 3, 4\}$) values of the collection $\langle 2, 2, 4, 5\rangle$, at most $\mathtt{N} = 1$ value is equal to value $\mathtt{VALUE} = 2$.

Typical

$\mathtt{N} > 0$
$\mathtt{N} < |\mathtt{VARIABLES}|$
$|\mathtt{VARIABLES}| > 1$

Symmetries

- N can be increased.
- An occurrence of a value of VARIABLES.var can be replaced by any other value that is different from VALUE.

Arg. properties Suffix-contractible wrt. VARIABLES.

See also

Arc generator	$SELF \mapsto$ collection(variables)
Arc arity	1
Arc constraint(s)	• variables.var = VALUE • IN_SET(variables.key, S)
Graph property(ies)	**NARC** $\leq$ N

Graph model

Since each arc constraint involves only one vertex (VALUE is fixed), we employ the *SELF* arc generator in order to produce a graph with a single loop on each vertex. Variables for which the corresponding position does not belong to the set S are removed from the final graph by the second condition of the arc-constraint.

Parts (A) and (B) of Figure 5.653 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the loops of the final graph are stressed in bold.

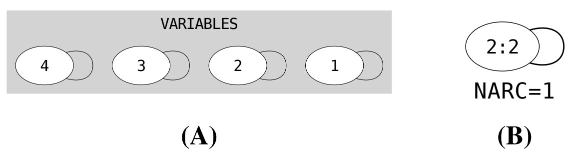

Figure 5.653: Initial and final graph of the OPEN_ATMOST constraint

5.304 OPEN_GLOBAL_CARDINALITY

DESCRIPTION LINKS GRAPH

Origin [438]

Constraint OPEN_GLOBAL_CARDINALITY(S, VARIABLES, VALUES)

Synonyms OPEN_GCC, OGCC.

Arguments

S : svar
VARIABLES : collection(var−dvar)
VALUES : collection(val−int, noccurrence−dvar)

Restrictions

$\texttt{S} \geq 1$
$\texttt{S} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)
required(VALUES, [val, noccurrence])
distinct(VALUES, val)
$\texttt{VALUES.noccurrence} \geq 0$
$\texttt{VALUES.noccurrence} \leq |\texttt{VARIABLES}|$

Purpose

Each value VALUES$[i]$.val ($1 \leq i \leq |\texttt{VALUES}|$) should be taken by exactly VALUES$[i]$.noccurrence variables of the VARIABLES collection for which the corresponding position belongs to the set S. Positions are numbered from 1.

Example

$$\left(\begin{array}{l}\{2,3,4\},\\ \langle 3,3,8,6\rangle,\\ \left\langle\begin{array}{ll}\texttt{val}-3 & \texttt{noccurrence}-1,\\ \texttt{val}-5 & \texttt{noccurrence}-0,\\ \texttt{val}-6 & \texttt{noccurrence}-1\end{array}\right\rangle\end{array}\right)$$

The OPEN_GLOBAL_CARDINALITY constraint holds since:

- Values 3, 5 and 6 respectively occur 1, 0 and 1 times within the collection $\langle 3,3,8,6\rangle$ (the first item 3 of $\langle 3,3,8,6\rangle$ is ignored since value 1 does not belong to the first argument $S = \{2,3,4\}$ of the OPEN_GLOBAL_CARDINALITY constraint).
- No constraint was specified for value 8.

Typical

$|\texttt{VARIABLES}| > 1$
range(VARIABLES.var) > 1
$|\texttt{VALUES}| > 1$
range(VALUES.noccurrence) > 1
$|\texttt{VARIABLES}| > |\texttt{VALUES}|$

Symmetries

- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.

Usage

In their article [438], W.-J. van Hoeve and J.-C. Régin motivate the OPEN_GLOBAL_CARDINALITY constraint by the following scheduling problem. Consider a set of activities (where each activity has a fixed duration 1 and a start variable) that can be processed on two factory lines such that all the activities that will be processed on a given line must be pairwise distinct. This can be modelled by using one OPEN_GLOBAL_CARDINALITY constraint for each line, involving all the start variables as well as a set variable whose final value specifies the set of activities assigned to that specific factory line.

Note that this can also be directly modelled by a single DIFFN constraint. This is done by introducing an assignment variable for each activity. The initial domain of each assignment variable consists of two values that respectively correspond to the two factory lines.

Remark

In their article [438], W.-J. van Hoeve and J.-C. Régin consider the case where we have no counter variables for the values, but rather some lower and upper bounds (i.e., in fact the OPEN_GLOBAL_CARDINALITY_LOW_UP constraint).

Algorithm

A slight adaptation of the flow model that handles the original GLOBAL_CARDINALITY constraint [353] is described in [438].

See also

common keyword: GLOBAL_CARDINALITY_LOW_UP *(assignment,counting constraint)*, OPEN_AMONG *(open constraint,counting constraint)*, OPEN_ATLEAST, OPEN_ATMOST *(open constraint,value constraint)*.

hard version: GLOBAL_CARDINALITY.

specialisation: OPEN_ALLDIFFERENT *(each active value[15] should occur at most once)*, OPEN_GLOBAL_CARDINALITY_LOW_UP *(*variable *replaced by* fixed interval*)*.

used in graph description: IN_SET.

Keywords

application area: assignment.

constraint arguments: constraint involving set variables.

constraint type: open constraint, value constraint, counting constraint.

filtering: flow.

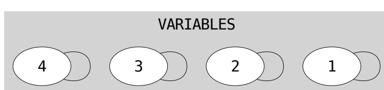
[15] An *active value* corresponds to a value occuring at a position mentionned in the set S.

For all items of VALUES:

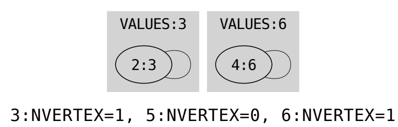
Arc input(s)	VARIABLES
Arc generator	*SELF* ↦ collection(variables)
Arc arity	1
Arc constraint(s)	• variables.var = VALUES.val • IN_SET(variables.key, S)
Graph property(ies)	**NVERTEX** = VALUES.noccurrence

Graph model Since we want to express one unary constraint for each value we use the "For all items of VALUES" iterator. The only difference with the graph model of the GLOBAL_CARDINALITY constraint is the arc constraint where we also specify that the position of the considered variable should belong to the first argument S.

Part (A) of Figure 5.654 shows the initial graphs associated with each value 3, 5 and 6 of the VALUES collection of the **Example** slot. Part (B) of Figure 5.654 shows the two corresponding final graphs respectively associated with values 3 and 6 that are both assigned to those variables of the VARIABLES collection for which the index belongs to S (since value 5 is not assigned to any variable of the VARIABLES collection the final graph associated with value 5 is empty). Since we use the **NVERTEX** graph property, the vertices of the final graphs are stressed in bold.



(A)



(B)

Figure 5.654: Initial and final graph of the OPEN_GLOBAL_CARDINALITY constraint

5.305 OPEN_GLOBAL_CARDINALITY_LOW_UP

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [438]

Constraint OPEN_GLOBAL_CARDINALITY_LOW_UP(S, VARIABLES, VALUES)

Arguments

S	:	svar
VARIABLES	:	collection(var−dvar)
VALUES	:	collection(val−int, omin−int, omax−int)

Restrictions

$\texttt{S} \geq 1$
$\texttt{S} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)
$|\texttt{VALUES}| > 0$
required(VALUES, [val, omin, omax])
distinct(VALUES, val)
$\texttt{VALUES.omin} \geq 0$
$\texttt{VALUES.omax} \leq |\texttt{VARIABLES}|$
$\texttt{VALUES.omin} \leq \texttt{VALUES.omax}$

Purpose Each value $\texttt{VALUES}[i].\texttt{val}$ $(1 \leq i \leq |\texttt{VALUES}|)$ should be taken by at least $\texttt{VALUES}[i].\texttt{omin}$ and at most $\texttt{VALUES}[i].\texttt{omax}$ variables of the VARIABLES collection for which the corresponding position belongs to the set S. Positions are numbered from 1.

Example

$$\left(\begin{array}{l}\{2,3,4\},\\ \langle 3,3,8,6\rangle,\\ \left\langle\begin{array}{lll}\texttt{val}-3 & \texttt{omin}-1 & \texttt{omax}-3,\\ \texttt{val}-5 & \texttt{omin}-0 & \texttt{omax}-1,\\ \texttt{val}-6 & \texttt{omin}-1 & \texttt{omax}-2\end{array}\right\rangle\end{array}\right)$$

The OPEN_GLOBAL_CARDINALITY_LOW_UP constraint holds since:

- Values 3, 5 and 6 are respectively used 1 $(1 \leq 1 \leq 3)$, 0 $(0 \leq 0 \leq 1)$ and 1 $(1 \leq 1 \leq 2)$ times within the collection $\langle 3,3,8,6\rangle$ (the first item 3 of $\langle 3,3,8,6\rangle$ is ignored since value 1 does not belong to the first argument $S = \{2,3,4\}$ of the OPEN_GLOBAL_CARDINALITY_LOW_UP constraint).
- No constraint was specified for value 8.

Typical

$|\texttt{VARIABLES}| > 1$
$\text{range}(\texttt{VARIABLES.var}) > 1$
$|\texttt{VALUES}| > 1$
$\texttt{VALUES.omin} \leq |\texttt{VARIABLES}|$
$\texttt{VALUES.omax} > 0$
$\texttt{VALUES.omax} \leq |\texttt{VARIABLES}|$
$|\texttt{VARIABLES}| > |\texttt{VALUES}|$

Symmetries

- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.

Usage

In their article [438], W.-J. van Hoeve and J.-C. Régin motivate the OPEN_GLOBAL_CARDINALITY_LOW_UP constraint by the following scheduling problem. Consider a set of activities (where each activity has a fixed duration 1 and a start variable) that can be processed on two factory lines such that all the activities that will be processed on a given line must be pairwise distinct. This can be modelled by using one OPEN_GLOBAL_CARDINALITY_LOW_UP constraint for each line, involving all the start variables as well as a set variable whose final value specifies the set of activities assigned to that specific factory line.

Note that this can also be directly modelled by a single DIFFN constraint. This is done by introducing an assignment variable for each activity. The initial domain of each assignment variable consists of two values that respectively correspond to the two factory lines.

Algorithm

A slight adaptation of the flow model that handles the original GLOBAL_CARDINALITY constraint [353] is described in [438].

See also

constraint arguments: constraint involving set variables.

constraint type: open constraint, value constraint, counting constraint.

filtering: flow.

[16] An *active value* corresponds to a value occuring at a position mentionned in the set S.

For all items of VALUES:

Arc input(s)	VARIABLES
Arc generator	$SELF \mapsto$ collection(variables)
Arc arity	1
Arc constraint(s)	• variables.var = VALUES.val • IN_SET(variables.key, S)
Graph property(ies)	• **NVERTEX** $\geq$ VALUES.omin • **NVERTEX** $\leq$ VALUES.omax

Graph model Since we want to express one unary constraint for each value we use the "For all items of VALUES" iterator. The only difference from the graph model of the GLOBAL_CARDINALITY_LOW_UP constraint is the arc constraint where we also specify that the position of the considered variable should belong to the first argument S.

Part (A) of Figure 5.655 shows the initial graphs associated with each value 3, 5 and 6 of the VALUES collection of the **Example** slot. Part (B) of Figure 5.655 shows the two corresponding final graphs respectively associated with values 3 and 6 that are both assigned to the variables of the VARIABLES collection (since value 5 is not assigned to any variable of the VARIABLES collection the final graph associated with value 5 is empty). Since we use the **NVERTEX** graph property, the vertices of the final graphs are stressed in bold.

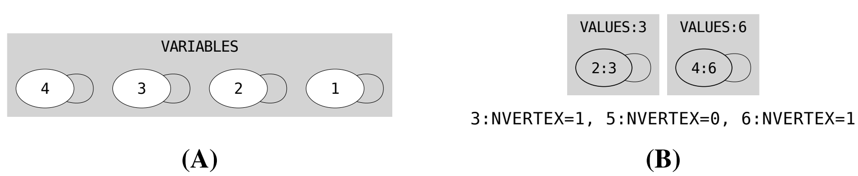

Figure 5.655: Initial and final graph of the OPEN_GLOBAL_CARDINALITY_LOW_UP constraint

5.306 OPEN_MAXIMUM

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Derived from MAXIMUM

Constraint OPEN_MAXIMUM(MAX, VARIABLES)

Arguments

MAX	:	dvar
VARIABLES	:	collection(var−dvar, bool−dvar)

Restrictions

$|\texttt{VARIABLES}| > 0$
required(VARIABLES, [var, bool])
VARIABLES.bool ≥ 0
VARIABLES.bool ≤ 1

Purpose MAX is the maximum value of the variables VARIABLES[i].var, $(1 \leq i \leq |\texttt{VARIABLES}|)$ for which VARIABLES[i].bool $= 1$ (at least one of the Boolean variables is set to 1).

Example

$$\left(5, \left\langle \begin{array}{ll} \texttt{var}-3 & \texttt{bool}-1, \\ \texttt{var}-1 & \texttt{bool}-0, \\ \texttt{var}-7 & \texttt{bool}-0, \\ \texttt{var}-5 & \texttt{bool}-1, \\ \texttt{var}-5 & \texttt{bool}-1 \end{array} \right\rangle \right)$$

The OPEN_MAXIMUM constraint holds since its first argument MAX $= 5$ is set to the maximum value of values $3, 1, 7, 5, 5$ for which the corresponding Boolean $1, 0, 0, 1, 1$ is set to 1 (i.e., values $3, 5, 5$).

Typical

$|\texttt{VARIABLES}| > 1$
range(VARIABLES.var) > 1

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to MAX as well as to the var attribute of all items of VARIABLES.

See also

comparison swapped: OPEN_MINIMUM.

hard version: MAXIMUM.

used in graph description: IN_SET.

Keywords

characteristic of a constraint: maximum, automaton, automaton without counters, reified automaton constraint.

constraint network structure: centered cyclic(1) constraint network(1).

constraint type: order constraint, open constraint, open automaton constraint.

Automaton Figure 5.656 depicts the automaton associated with the OPEN_MAXIMUM constraint. Let $\mathtt{VAR}_i, \mathtt{B}_i$ be the i^{th} item of the VARIABLES collection. To each triple $(\mathtt{MAX}, \mathtt{VAR}_i, \mathtt{B}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\mathtt{B}_i = 1 \wedge \mathtt{MAX} < \mathtt{VAR}_i \Leftrightarrow S_i = 0) \wedge (\mathtt{B}_i = 1 \wedge \mathtt{MAX} = \mathtt{VAR}_i \Leftrightarrow S_i = 1) \wedge (\mathtt{B}_i = 1 \wedge \mathtt{MAX} > \mathtt{VAR}_i \Leftrightarrow S_i = 2) \wedge (\mathtt{B}_i = 0 \wedge \mathtt{MAX} < \mathtt{VAR}_i \Leftrightarrow S_i = 3) \wedge (\mathtt{B}_i = 0 \wedge \mathtt{MAX} = \mathtt{VAR}_i \Leftrightarrow S_i = 4) \wedge (\mathtt{B}_i = 0 \wedge \mathtt{MAX} > \mathtt{VAR}_i \Leftrightarrow S_i = 5)$.

5.307 OPEN_MINIMUM

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Derived from MINIMUM

Constraint OPEN_MINIMUM(MIN, VARIABLES)

Arguments

MIN	:	dvar
VARIABLES	:	collection(var−dvar, bool−dvar)

Restrictions

$|\texttt{VARIABLES}| > 0$
required(VARIABLES, [var, bool])
$\texttt{VARIABLES.bool} \geq 0$
$\texttt{VARIABLES.bool} \leq 1$

Purpose

MIN is the minimum value of the variables $\texttt{VARIABLES}[i].\texttt{var}$, $(1 \leq i \leq |\texttt{VARIABLES}|)$ for which $\texttt{VARIABLES}[i].\texttt{bool} = 1$ (at least one of the Boolean variables is set to 1).

Example

$$\left(3, \left\langle \begin{array}{ll} \texttt{var}-3 & \texttt{bool}-1, \\ \texttt{var}-1 & \texttt{bool}-0, \\ \texttt{var}-7 & \texttt{bool}-0, \\ \texttt{var}-5 & \texttt{bool}-1, \\ \texttt{var}-5 & \texttt{bool}-1 \end{array} \right\rangle \right)$$

The OPEN_MINIMUM constraint holds since its first argument $\texttt{MIN} = 3$ is set to the minimum value of values $3, 1, 7, 5, 5$ for which the corresponding Boolean $1, 0, 0, 1, 1$ is set to 1 (i.e., values $3, 5, 5$).

Typical

$|\texttt{VARIABLES}| > 1$
range(VARIABLES.var) > 1

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to MIN as well as to the var attribute of all items of VARIABLES.

Remark The OPEN_MINIMUM constraint is used in the reformulation of the TREE_RANGE constraint.

See also

comparison swapped: OPEN_MAXIMUM.

hard version: MINIMUM.

used in graph description: IN_SET.

uses in its reformulation: TREE_RANGE.

Keywords

characteristic of a constraint: minimum, automaton, automaton without counters, reified automaton constraint.

constraint network structure: centered cyclic(1) constraint network(1).

constraint type: order constraint, open constraint, open automaton constraint.

Automaton Figure 5.658 depicts the automaton associated with the OPEN_MINIMUM constraint. Let $\texttt{VAR}_i, \texttt{B}_i$ be the i^{th} item of the VARIABLES collection. To each triple $(\texttt{MIN}, \texttt{VAR}_i, \texttt{B}_i)$ corresponds a signature variable S_i as well as the following signature constraint: $(\texttt{B}_i = 1 \wedge \texttt{MIN} < \texttt{VAR}_i \Leftrightarrow S_i = 0) \wedge (\texttt{B}_i = 1 \wedge \texttt{MIN} = \texttt{VAR}_i \Leftrightarrow S_i = 1) \wedge (\texttt{B}_i = 1 \wedge \texttt{MIN} > \texttt{VAR}_i \Leftrightarrow S_i = 2) \wedge (\texttt{B}_i = 0 \wedge \texttt{MIN} < \texttt{VAR}_i \Leftrightarrow S_i = 3) \wedge (\texttt{B}_i = 0 \wedge \texttt{MIN} = \texttt{VAR}_i \Leftrightarrow S_i = 4) \wedge (\texttt{B}_i = 0 \wedge \texttt{MIN} > \texttt{VAR}_i \Leftrightarrow S_i = 5)$.

5.308 OPPOSITE_SIGN

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic.

Constraint OPPOSITE_SIGN(VAR1, VAR2)

Arguments

VAR1	:	dvar
VAR2	:	dvar

Restriction

Purpose Enforce the fact that the product of the first and second variables is less than or equal to 0.

Example $(6, -3)$

The OPPOSITE_SIGN constraint holds since 6 and -3 do not have the same sign.

Typical VAR1 $\neq 0$

Symmetry Arguments are permutable w.r.t. permutation (VAR1, VAR2).

See also **comparison swapped:** SAME_SIGN.

implies (if swap arguments): ABS_VALUE.

Keywords **constraint arguments:** binary constraint.

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

5.309 OR

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Logic

Constraint $\text{OR}(\texttt{VAR}, \texttt{VARIABLES})$

Synonym REL.

Arguments

$\texttt{VAR} : \texttt{dvar}$
$\texttt{VARIABLES} : \texttt{collection}(\texttt{var}-\texttt{dvar})$

Restrictions

$\texttt{VAR} \geq 0$
$\texttt{VAR} \leq 1$
$|\texttt{VARIABLES}| \geq 2$
$\texttt{required}(\texttt{VARIABLES}, \texttt{var})$
$\texttt{VARIABLES.var} \geq 0$
$\texttt{VARIABLES.var} \leq 1$

Purpose Let VARIABLES be a collection of 0-1 variables $\texttt{VAR}_1, \texttt{VAR}_2, \ldots, \texttt{VAR}_n$ $(n \geq 2)$. Enforce $\texttt{VAR} = \texttt{VAR}_1 \vee \texttt{VAR}_2 \vee \cdots \vee \texttt{VAR}_n$.

Example

$(0, \langle 0, 0\rangle)$
$(1, \langle 0, 1\rangle)$
$(1, \langle 1, 0\rangle)$
$(1, \langle 1, 1\rangle)$
$(1, \langle 1, 0, 1\rangle)$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Functional dependency: VAR determined by VARIABLES.
- Contractible wrt. VARIABLES when $\texttt{VAR} = 0$.
- Extensible wrt. VARIABLES when $\texttt{VAR} = 1$.
- Aggregate: $\texttt{VAR}(\vee)$, $\texttt{VARIABLES}(\texttt{union})$.

See also **common keyword:** AND, CLAUSE_OR, EQUIVALENT, IMPLY, NAND, NOR, XOR *(Boolean constraint)*.

implies: ATLEAST_NVALUE, MAXIMUM.

Keywords **characteristic of a constraint:** automaton, automaton without counters, reified automaton constraint.

constraint arguments: pure functional dependency.

constraint network structure: Berge-acyclic constraint network.

constraint type: Boolean constraint.

filtering: arc-consistency.

modelling: disjunction, functional dependency.

Cond. implications

- OR(VAR, VARIABLES)
  with $|\mathtt{VARIABLES}| > 2$
  implies SOME_EQUAL(VARIABLES).

- OR(VAR, VARIABLES)
  with $\mathtt{VAR} = 0$
  implies NOR(VAR, VARIABLES)
  when $\mathtt{VAR} = 1$.

- OR(VAR, VARIABLES)
  with $\mathtt{VAR} = 1$
  implies NOR(VAR, VARIABLES)
  when $\mathtt{VAR} = 0$.

Automaton Figure 5.660 depicts a first deterministic automaton without counter associated with the OR constraint. To the first argument VAR of the OR constraint corresponds the first signature variable. To each variable $\mathtt{VAR}_i$ of the second argument VARIABLES of the OR constraint corresponds the next signature variable. There is no signature constraint.

5.310 ORCHARD

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [235]

Constraint ORCHARD(NROW, TREES)

Arguments

NROW : dvar
TREES : collection(index−int, x−dvar, y−dvar)

Restrictions

NROW ≥ 0
TREES.index ≥ 1
TREES.index $\leq$ |TREES|
required(TREES, [index, x, y])
distinct(TREES, index)
TREES.x ≥ 0
TREES.y ≥ 0

Purpose

Orchard problem [235]:

> "*Your aid I want, Nine trees to plant, In rows just half a score, And let there be, In each row, three—Solve this: I ask no more!*"

Example

$$\left(10,\left\langle\begin{array}{lll}\texttt{index}-1 & \texttt{x}-0 & \texttt{y}-0,\\ \texttt{index}-2 & \texttt{x}-4 & \texttt{y}-0,\\ \texttt{index}-3 & \texttt{x}-8 & \texttt{y}-0,\\ \texttt{index}-4 & \texttt{x}-2 & \texttt{y}-4,\\ \texttt{index}-5 & \texttt{x}-4 & \texttt{y}-4,\\ \texttt{index}-6 & \texttt{x}-6 & \texttt{y}-4,\\ \texttt{index}-7 & \texttt{x}-0 & \texttt{y}-8,\\ \texttt{index}-8 & \texttt{x}-4 & \texttt{y}-8,\\ \texttt{index}-9 & \texttt{x}-8 & \texttt{y}-8\end{array}\right\rangle\right)$$

The 10 alignments of 3 trees correspond to the following triples of trees: $(1,2,3)$, $(1,4,8)$, $(1,5,9)$, $(2,4,7)$, $(2,5,8)$, $(2,6,9)$, $(3,5,7)$, $(3,6,8)$, $(4,5,6)$, $(7,8,9)$. Figure 5.664 shows the 9 trees and the 10 alignments corresponding to the example.

Typical

NROW > 0
|TREES| > 3

Symmetries

- Items of TREES are permutable.
- Attributes of TREES are permutable w.r.t. permutation (index) (x, y) (*permutation applied to all items*).
- One and the same constant can be added to the x attribute of all items of TREES.
- One and the same constant can be added to the y attribute of all items of TREES.

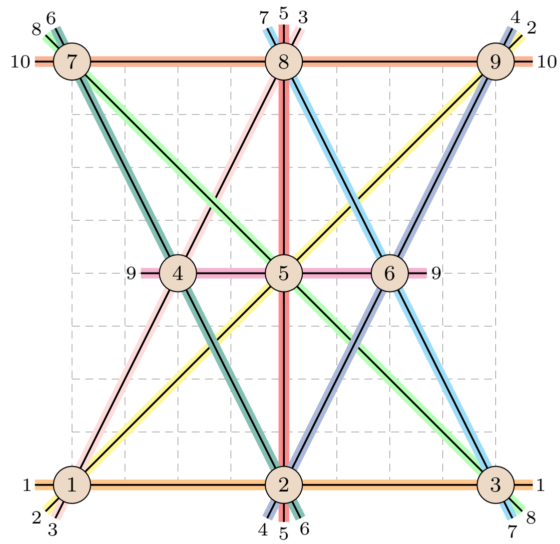

Figure 5.664: Nine trees with 10 alignments of 3 trees

Arg. properties Functional dependency: `NROW` determined by `TREES`.

Keywords **characteristic of a constraint:** hypergraph.

constraint arguments: pure functional dependency.

geometry: geometrical constraint, alignment.

modelling: functional dependency.

Arc input(s)	TREES
Arc generator	$CLIQUE(<) \mapsto$ collection(trees1, trees2, trees3)
Arc arity	3
Arc constraint(s)	$\sum\begin{pmatrix} \texttt{trees1.x} * \texttt{trees2.y} - \texttt{trees1.x} * \texttt{trees3.y}, \\ \texttt{trees1.y} * \texttt{trees3.x} - \texttt{trees1.y} * \texttt{trees2.x}, \\ \texttt{trees2.x} * \texttt{trees3.y} - \texttt{trees2.y} * \texttt{trees3.x} \end{pmatrix} = 0$
Graph property(ies)	**NARC**= NROW

Graph model The arc generator $CLIQUE(<)$ with an arity of three is used in order to generate all the arcs of the directed hypergraph. Each arc is an ordered triple of trees. We use the restriction $<$ in order to generate a single arc for each set of three trees. This is required, since otherwise we would count more than once a given alignment of three trees. The formula used within the arc constraint expresses the fact that the three points of respective coordinates $(\texttt{trees}_1.\texttt{x}, \texttt{trees}_1.\texttt{y})$, $(\texttt{trees}_2.\texttt{x}, \texttt{trees}_2.\texttt{y})$ and $(\texttt{trees}_3.\texttt{x}, \texttt{trees}_3.\texttt{y})$ are aligned. It corresponds to the development of the expression:

$$\begin{vmatrix} \texttt{trees}_1.\texttt{x} & \texttt{trees}_2.\texttt{y} & 1 \\ \texttt{trees}_2.\texttt{x} & \texttt{trees}_2.\texttt{y} & 1 \\ \texttt{trees}_3.\texttt{x} & \texttt{trees}_3.\texttt{y} & 1 \end{vmatrix} = 0$$

5.311 ORDER

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Derived from SORT_PERMUTATION

Constraint ORDER(VECTORS, PERMUTATION)

Type

VECTOR : collection(var−dvar)

Arguments

VECTORS : collection(vec − VECTOR)
PERMUTATION : collection(var−dvar)

Restrictions

$|\mathtt{VECTOR}| \geq 1$
$|\mathtt{VECTORS}| \geq 1$
required(VECTORS, vec)
same_size(VECTORS, vec)
required(PERMUTATION, var)
PERMUTATION.var ≥ 1
PERMUTATION.var $\leq$ |PERMUTATION|
|PERMUTATION| = |VECTORS|

Purpose Given a collection of distinct VECTORS, enforces PERMUTATION.var$[i]$ to be equal to the position of vector VECTORS.vec$[i]$ within the sorted vectors of the collection VECTORS.

Example

$$\left(\begin{array}{l}\left\langle\begin{array}{l}\mathtt{vec}-\langle 1,1,2,2\rangle,\\ \mathtt{vec}-\langle 2,1,2,1\rangle,\\ \mathtt{vec}-\langle 2,1,1,1\rangle,\\ \mathtt{vec}-\langle 1,1,1,2\rangle,\\ \mathtt{vec}-\langle 1,2,2,1\rangle,\\ \mathtt{vec}-\langle 1,1,1,1\rangle,\\ \mathtt{vec}-\langle 2,2,1,1\rangle,\\ \mathtt{vec}-\langle 2,1,1,2\rangle\end{array}\right\rangle,\\ \langle 3,7,5,2,4,1,8,6\rangle\end{array}\right)$$

The ORDER constraint holds since:

- The vector $\langle 1,1,2,2\rangle$ is in the third position of the sorted collection VECTORS,
- The vector $\langle 2,1,2,1\rangle$ is in the seventh position of the sorted collection VECTORS,
- The vector $\langle 2,1,1,1\rangle$ is in the fifth position of the sorted collection VECTORS,
- The vector $\langle 1,1,1,2\rangle$ is in the second position of the sorted collection VECTORS,
- The vector $\langle 1,2,2,1\rangle$ is in the fourth position of the sorted collection VECTORS,
- The vector $\langle 1,1,1,1\rangle$ is in the first position of the sorted collection VECTORS,
- The vector $\langle 2,2,1,1\rangle$ is in the eigth position of the sorted collection VECTORS,

- The vector $\langle 2, 1, 1, 2\rangle$ is in the sixth position of the sorted collection VECTORS.

Typical

$|\texttt{VECTOR}| > 1$
$|\texttt{VECTORS}| > 1$

Arg. properties

Functional dependency: PERMUTATION determined by VECTORS.

See also

common keyword: SORT_PERMUTATION *(sort, permutation)*.

Keywords

characteristic of a constraint: sort.

combinatorial object: permutation.

constraint type: predefined constraint.

modelling: functional dependency.

5.312 ORDERED_ATLEAST_NVECTOR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Conjoin ATLEAST_NVECTOR and LEX_CHAIN_LESSEQ.

Constraint ORDERED_ATLEAST_NVECTOR(NVEC, VECTORS)

Synonyms ORDERED_ATLEAST_NVECTORS, ORDERED_ATLEAST_NPOINT, ORDERED_ATLEAST_NPOINTS.

Type

VECTOR : collection(var−dvar)

Arguments

NVEC : dvar
VECTORS : collection(vec − VECTOR)

Restrictions

$|\text{VECTOR}| \geq 1$
$\text{NVEC} \geq 0$
$\text{NVEC} \leq |\text{VECTORS}|$
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose

Enforces the following two conditions:

1. The number of distinct tuples of values taken by the vectors of the collection VECTORS is greater than or equal to NVEC. Two tuples of values $\langle A_1, A_2, \ldots, A_m\rangle$ and $\langle B_1, B_2, \ldots, B_m\rangle$ are *distinct* if and only if there exist an integer $i \in [1, m]$ such that $A_i \neq B_i$.
2. For each pair of consecutive vectors VECTOR_i and VECTOR_{i+1} of the VECTORS collection we have that VECTOR_i is lexicographically less than or equal to VECTOR_{i+1}. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically less than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is lexicographically less than or equal to $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$$\left(2, \left\langle \begin{array}{l} \texttt{vec} - \langle 5,6\rangle, \\ \texttt{vec} - \langle 5,6\rangle, \\ \texttt{vec} - \langle 5,6\rangle, \\ \texttt{vec} - \langle 9,3\rangle, \\ \texttt{vec} - \langle 9,4\rangle \end{array} \right\rangle \right)$$

The ORDERED_ATLEAST_NVECTOR constraint holds since:

1. The collection VECTORS involves at least 2 distinct tuples of values (i.e., in fact the 3 distinct tuples $\langle 5,6\rangle$, $\langle 9,3\rangle$ and $\langle 9,4\rangle$).
2. The vectors of the collection VECTORS are sorted in increasing lexicographical order.

Typical

$|\texttt{VECTOR}| > 1$
$\texttt{NVEC} > 0$
$\texttt{NVEC} < |\texttt{VECTORS}|$
$|\texttt{VECTORS}| > 1$

Symmetry

NVEC can be decreased to any value ≥ 0.

Reformulation

The ORDERED_ATLEAST_NVECTOR constraint can be reformulated as a conjunction of a ATLEAST_NVECTOR and a LEX_CHAIN_LESSEQ constraints.

See also

common keyword: NVECTOR *(vector)*.

comparison swapped: ORDERED_ATMOST_NVECTOR.

implied by: ORDERED_NVECTOR *($\geq$ NVEC replaced by $=$ NVEC)*.

Graph property(ies)	**NCC** $\geq$ NVEC

Graph model Parts (A) and (B) of Figure 5.665 respectively show the initial and final graph of the second graph constraint associated with the **Example** slot. Since we use the **NCC** graph property in this second graph constraint, we show the different connected components of the final graph. Each strongly connected component corresponds to a tuple of values that is assigned to some vectors of the VECTORS collection. The 3 following tuple of values $\langle 5, 6\rangle$, $\langle 9, 3\rangle$ and $\langle 9, 4\rangle$ are used by the vectors of the VECTORS collection.

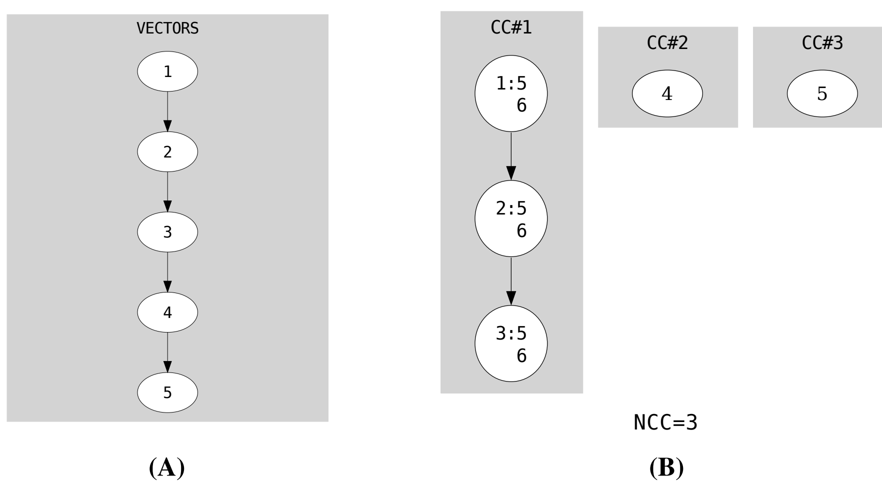

Figure 5.665: Initial and final graph of the ORDERED_ATLEAST_NVECTOR constraint

5.313 ORDERED_ATMOST_NVECTOR

DESCRIPTION LINKS GRAPH

Origin

Conjoin ATMOST_NVECTOR and LEX_CHAIN_LESSEQ.

Constraint

ORDERED_ATMOST_NVECTOR(NVEC, VECTORS)

Synonyms

ORDERED_ATMOST_NVECTORS, ORDERED_ATMOST_NPOINT, ORDERED_ATMOST_NPOINTS.

Type

VECTOR : collection(var−dvar)

Arguments

NVEC : dvar
VECTORS : collection(vec − VECTOR)

Restrictions

$|\mathtt{VECTOR}| \geq 1$
$\mathtt{NVEC} \geq \mathtt{min}(1, |\mathtt{VECTORS}|)$
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose

Enforces the following two conditions:

1. The number of distinct tuples of values taken by the vectors of the collection VECTORS is less than or equal to NVEC. Two tuples of values $\langle A_1, A_2, \ldots, A_m\rangle$ and $\langle B_1, B_2, \ldots, B_m\rangle$ are *distinct* if and only if there exist an integer $i \in [1, m]$ such that $A_i \neq B_i$.
2. For each pair of consecutive vectors $\mathtt{VECTOR}_i$ and $\mathtt{VECTOR}_{i+1}$ of the VECTORS collection we have that $\mathtt{VECTOR}_i$ is lexicographically less than or equal to $\mathtt{VECTOR}_{i+1}$. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically less than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is lexicographically less than or equal to $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$$\left(3, \left\langle \begin{array}{l} \mathtt{vec} - \langle 5, 6\rangle, \\ \mathtt{vec} - \langle 5, 6\rangle, \\ \mathtt{vec} - \langle 5, 6\rangle, \\ \mathtt{vec} - \langle 9, 3\rangle, \\ \mathtt{vec} - \langle 9, 3\rangle \end{array} \right\rangle\right)$$

The ORDERED_ATMOST_NVECTOR constraint holds since:

1. The collection VECTORS involves at most 3 distinct tuples of values (i.e., in fact the 2 distinct tuples $\langle 5, 6\rangle$ and $\langle 9, 3\rangle$).
2. The vectors of the collection VECTORS are sorted in increasing lexicographical order.

Typical

$|\mathtt{VECTOR}| > 1$
$\mathtt{NVEC} > 1$
$\mathtt{NVEC} < |\mathtt{VECTORS}|$
$|\mathtt{VECTORS}| > 1$

Symmetry

NVEC can be increased.

Arg. properties

Contractible wrt. VECTORS.

Reformulation

The ORDERED_ATMOST_NVECTOR constraint can be reformulated as a conjunction of a ATMOST_NVECTOR and a LEX_CHAIN_LESSEQ constraints.

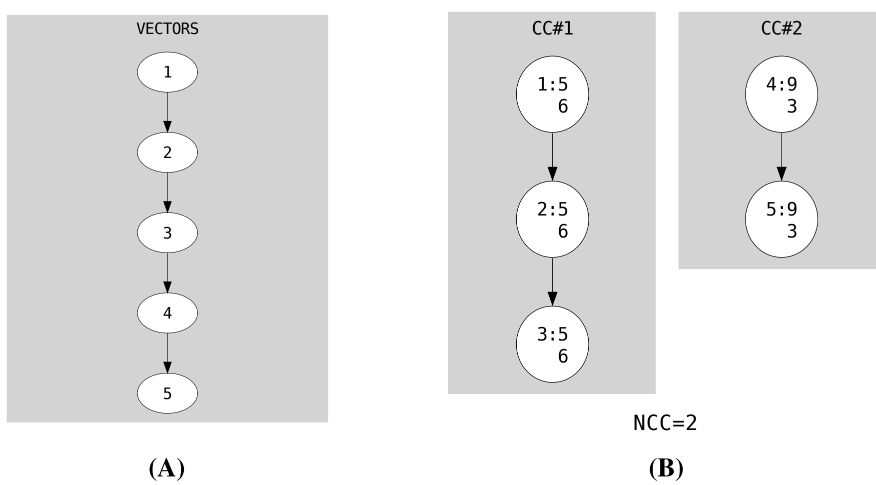

Figure 5.666: Initial and final graph of the ORDERED_ATMOST_NVECTOR constraint

5.314 ORDERED_GLOBAL_CARDINALITY

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [323]

Constraint ORDERED_GLOBAL_CARDINALITY(VARIABLES, VALUES)

Usual name ORDGCC

Synonym ORDERED_GCC.

Arguments

VARIABLES	:	collection(var−dvar)
VALUES	:	collection(val−int, omax−int)

Restrictions

required(VARIABLES, var)
|VALUES| > 0
required(VALUES, [val, omax])
increasing_seq(VALUES, [val])
VALUES.omax ≥ 0
VALUES.omax ≤ |VARIABLES|

Purpose

For each $i \in [1, |\mathtt{VALUES}|]$, the values of the corresponding set of values VALUES[j].val ($i \leq j \leq |\mathtt{VALUES}|$) should be taken by at most VALUES[i].omax variables of the VARIABLES collection.
From that previous definition, the omax attributes are decreasing.

Example

$$\left(\begin{array}{l}\langle 2,0,1,0,0\rangle,\\ \langle \mathtt{val}-0\ \mathtt{omax}-5, \mathtt{val}-1\ \mathtt{omax}-3, \mathtt{val}-2\ \mathtt{omax}-1\rangle\end{array}\right)$$

The ORDERED_GLOBAL_CARDINALITY constraint holds since the values of the three sets of values $\{0,1,2\}$, $\{1,2\}$ and $\{2\}$ are respectively used no more than 5, 3 and 1 times within the collection $\langle 2,0,1,0,0\rangle$.

Symmetry Items of VARIABLES are permutable.

Arg. properties Contractible wrt. VALUES.

Usage

The ORDERED_GLOBAL_CARDINALITY can be used in order to restrict the way we assign the values of the VALUES collection to the variables of the VARIABLES collection. It expresses the fact that, when we use a value v, we implicitly also use all values that are less than or equal to v. As depicted by Figure 5.667 this is the case, for example, for a *soft cumulative* constraint where we want to control the shape of cumulative profile by providing for each instant i a variable h_i that gives the height of the cumulative profile at instant i. These variables h_i are passed as the first argument of the ORDERED_GLOBAL_CARDINALITY constraint. Then the omax attribute of the j-th item of the VALUES collection gives the maximum number of instants for which the height of the cumulative profile is greater than or equal to value VALUES[j].val. In Figure 5.667 we should have:

- no more than 1 height variable greater than or equal to 2,
- no more than 3 height variables greater than or equal to 1,
- no more than 5 height variables greater than or equal to 0.

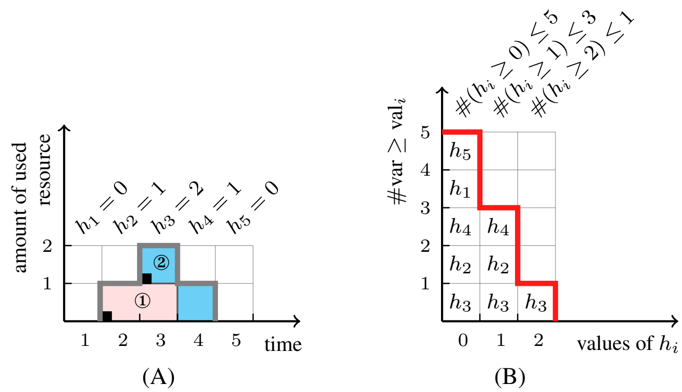

Figure 5.667: (A) A cumulative profile wrt two tasks ① and ②, and its corresponding height variables h_1, $h_2, \ldots, h_5$ giving at each instant how many resource is used (B) profile of value utilisation of the height variables (e.g., value 1 is assigned to variables h_3, h_2, h_4 and therefore used three times)

Remark

The original definition of the ORDERED_GLOBAL_CARDINALITY constraint mentions a third argument, namely the minimum number of occurrences of the smallest value. We omit it since it is redundant.

An other closely related constraint, the COST_ORDERED_GLOBAL_CARDINALITY constraint was introduced in [323] in order to model the fact that overloads costs may depend of the instant where they occur.

Algorithm

A filtering algorithm achieving arc-consistency in $O(|\texttt{VARIABLES}|+|\texttt{VALUES}|)$ is described in [323]. It is based on the equivalence between the following two statements:

1. the ORDERED_GLOBAL_CARDINALITY constraint has a solution,
2. all variables of the VARIABLES collection assigned to their respective minimum values correspond to a solution to the ORDERED_GLOBAL_CARDINALITY constraint.

Reformulation

The ORDERED_GLOBAL_CARDINALITY($\langle \texttt{var}-V_1, \texttt{var}-V_2, \ldots, \texttt{var}-V_{|\texttt{VARIABLES}|}\rangle$, $\langle \texttt{val}-v_1\ \texttt{omax}-o_1, \texttt{val}-v_2\ \texttt{omax}-o_2, \ldots, \texttt{val}-v_{|\texttt{VALUES}|}\ \texttt{omax}-o_{|\texttt{VALUES}|}\rangle$) constraint can be reformulated into a GLOBAL_CARDINALITY($\langle \texttt{var}-V_1, \texttt{var}-V_2, \ldots, \texttt{var}-V_{|\texttt{VARIABLES}|}\rangle$, $\langle \texttt{val}-v_1\ \texttt{noccurrence}-N_1, \texttt{val}-v_2\ \texttt{noccurrence}-N_2, \ldots, \texttt{val}-v_{|\texttt{VALUES}|}\ \texttt{noccurrence}-N_{|\texttt{VALUES}|}\rangle$) and $|\texttt{VALUES}|$ sliding linear inequalities constraints of the form:

$$\begin{aligned} N_1 + N_2 + \cdots + N_{|\texttt{VALUES}|} &\leq o_1, \\ N_2 + \cdots + N_{|\texttt{VALUES}|} &\leq o_2, \\ \cdots\cdots\cdots\cdots\cdots\cdots &, \\ N_{|\texttt{VALUES}|} &\leq o_{|\texttt{VALUES}|}. \end{aligned}$$

However, with the next example, T. Petit and J.-C. Régin have shown that this reformulation hinders propagation:

1. $V_1 \in \{0,1\}$, $V_2 \in \{0,1\}$, $V_3 \in \{0,1,2\}$, $V_4 \in \{2,3\}$, $V_5 \in \{2,3\}$.
2. GLOBAL_CARDINALITY($\langle V_1, V_2, V_3, V_4, V_5 \rangle$, $\langle \texttt{val} - 1\ \texttt{noccurrence} - N_1, \texttt{val} - 2\ \texttt{noccurrence} - N_2, \texttt{val} - 3\ \texttt{noccurrence} - N_3 \rangle$),
3. $N_1 + N_2 + N_3 \leq 3 \wedge N_2 + N_3 \leq 2 \wedge N_3 \leq 2$.

The previous reformulation does not remove value 2 from the domain of variable V_3.

root concept: GLOBAL_CARDINALITY.

Keywords

application area: assignment.

constraint type: value constraint, order constraint.

filtering: arc-consistency.

For all items of VALUES:

Arc input(s) VARIABLES

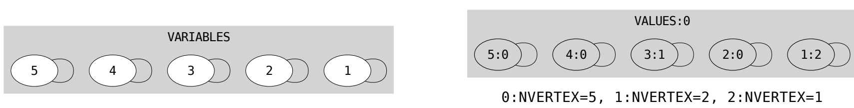
Arc generator $SELF \mapsto$collection(variables)

Arc arity 1

Arc constraint(s) variables.var $\geq$ VALUES.val

Graph property(ies) **NVERTEX** $\leq$ VALUES.omax

Graph model Since we want to express one unary constraint for each value we use the "For all items of VALUES" iterator. Part (A) of Figure 5.668 shows the initial graphs associated with each value 0, 1 and 2 of the VALUES collection of the **Example** slot. Part (B) of Figure 5.668 shows the corresponding final graph associated with value 0. Since we use the **NVERTEX** graph property, the vertices of the final graph is stressed in bold.



(A) **(B)**

Figure 5.668: Initial and final graph of the ORDERED_GLOBAL_CARDINALITY constraint

5.315 ORDERED_NVECTOR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from NVECTOR.

Constraint ORDERED_NVECTOR(NVEC, VECTORS)

Synonyms ORDERED_NVECTORS, ORDERED_NPOINT, ORDERED_NPOINTS.

Type

VECTOR : collection(var−dvar)

Arguments

NVEC : dvar
VECTORS : collection(vec − VECTOR)

Restrictions

$|\texttt{VECTOR}| \geq 1$
$\texttt{NVEC} \geq \texttt{min}(1, |\texttt{VECTORS}|)$
$\texttt{NVEC} \leq |\texttt{VECTORS}|$
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose

Enforces the following two conditions:

1. NVEC is the number of distinct tuples of values assigned to the vectors of the collection VECTORS. Two tuples of values $\langle A_1, A_2, \ldots, A_m\rangle$ and $\langle B_1, B_2, \ldots, B_m\rangle$ are *distinct* if and only if there exist an integer $i \in [1, m]$ such that $A_i \neq B_i$.
2. For each pair of consecutive vectors $\texttt{VECTOR}_i$ and $\texttt{VECTOR}_{i+1}$ of the VECTORS collection we have that $\texttt{VECTOR}_i$ is lexicographically less than or equal to $\texttt{VECTOR}_{i+1}$. Given two vectors, $\vec{X}$ and $\vec{Y}$ of n components, $\langle X_0, \ldots, X_{n-1}\rangle$ and $\langle Y_0, \ldots, Y_{n-1}\rangle$, $\vec{X}$ is *lexicographically less than or equal to* $\vec{Y}$ if and only if $n = 0$ or $X_0 < Y_0$ or $X_0 = Y_0$ and $\langle X_1, \ldots, X_{n-1}\rangle$ is lexicographically less than or equal to $\langle Y_1, \ldots, Y_{n-1}\rangle$.

Example

$$\left(2, \left\langle \begin{array}{l} \texttt{vec} - \langle 5, 6\rangle, \\ \texttt{vec} - \langle 5, 6\rangle, \\ \texttt{vec} - \langle 5, 6\rangle, \\ \texttt{vec} - \langle 9, 3\rangle, \\ \texttt{vec} - \langle 9, 3\rangle \end{array} \right\rangle \right)$$

The ORDERED_NVECTOR constraint holds since:

1. Its first argument $\texttt{NVEC} = 2$ is set to the number of distinct tuples of values (i.e., tuples $\langle 5, 6\rangle$ and $\langle 9, 3\rangle$) occurring within the collection VECTORS.
2. The vectors of the collection VECTORS are sorted in increasing lexicographical order.

Typical

$|\texttt{VECTOR}| > 1$
$\texttt{NVEC} > 1$
$\texttt{NVEC} < |\texttt{VECTORS}|$
$|\texttt{VECTORS}| > 1$

Arg. properties

- Functional dependency: NVEC determined by VECTORS.
- Contractible wrt. VECTORS when $\texttt{NVEC} = 1$ and $|\texttt{VECTORS}| > 0$.
- Contractible wrt. VECTORS when $\texttt{NVEC} = |\texttt{VECTORS}|$.

Reformulation

The ORDERED_NVECTOR constraint can be reformulated as a conjunction of a NVECTOR and a LEX_CHAIN_LESSEQ constraints.

See also

implies: LEX_CHAIN_LESSEQ *(*NVEC *of constraint* ORDERED_NVECTOR *removed)*, NVECTOR, ORDERED_ATLEAST_NVECTOR *(*$=$ NVEC *replaced by* $\geq$ NVEC*)*, ORDERED_ATMOST_NVECTOR *(*$=$ NVEC *replaced by* $\leq$ NVEC*)*.

related: INCREASING_NVALUE_CHAIN.

root concept: INCREASING_NVALUE.

used in graph description: LEX_LESS, LEX_LESSEQ.

Keywords

characteristic of a constraint: vector.

constraint type: counting constraint, order constraint.

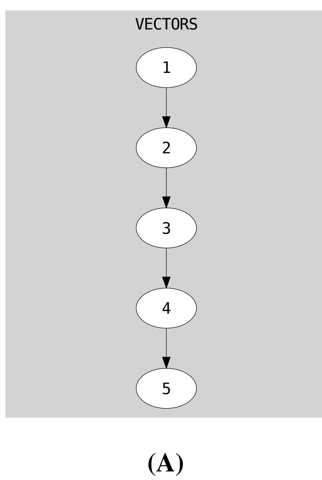
modelling: functional dependency.

symmetry: symmetry.

Arc input(s)	VECTORS
Arc generator	$PATH \mapsto$ collection(vectors1, vectors2)
Arc arity	2
Arc constraint(s)	LEX_LESSEQ(vectors1.vec, vectors2.vec)
Graph property(ies)	**NARC**$=$ |VECTORS| -1

Arc input(s)	VECTORS
Arc generator	$PATH \mapsto$ collection(vectors1, vectors2)
Arc arity	2
Arc constraint(s)	LEX_LESS(vectors1.vec, vectors2.vec)
Graph property(ies)	**NCC**$=$ NVEC

Graph model Parts (A) and (B) of Figure 5.669 respectively show the initial and final graph of the second graph constraint associated with the **Example** slot. Since we use the **NCC** graph property in this second graph constraint, we show the different connected components of the final graph. Each strongly connected component corresponds to a tuple of values that is assigned to some vectors of the VECTORS collection. The 2 following tuple of values $\langle 5, 6\rangle$ and $\langle 9, 3\rangle$ are used by the vectors of the VECTORS collection.



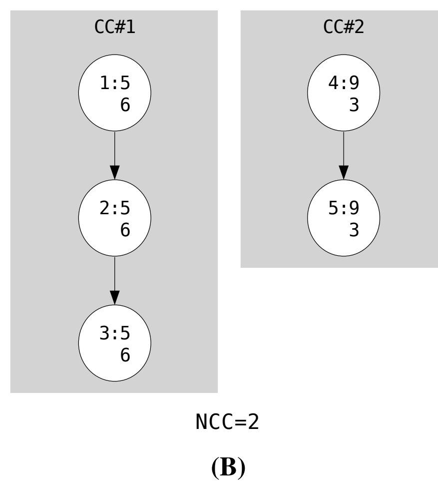


Figure 5.669: Initial and final graph of the ORDERED_NVECTOR constraint

5.316 ORTH_LINK_ORI_SIZ_END

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Used by several constraints between orthotopes

Constraint ORTH_LINK_ORI_SIZ_END(ORTHOTOPE)

Argument ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Restrictions
|ORTHOTOPE| >0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori $\leq$ ORTHOTOPE.end

Purpose Enforce for each item of the ORTHOTOPE collection the constraint ori + siz = end.

Example (⟨ori − 2 siz − 2 end − 4, ori − 1 siz − 3 end − 4⟩)

The ORTH_LINK_ORI_SIZ_END constraint holds since the two items ⟨ori − 2 siz − 2 end − 4⟩ and ⟨ori − 1 siz − 3 end − 4⟩ respectively verify the conditions $2+2=4$ and $1+3=4$.

Typical
|ORTHOTOPE| >1
ORTHOTOPE.siz >0

Symmetries
- Items of ORTHOTOPE are permutable.
- One and the same constant can be added to the ori and end attributes of all items of ORTHOTOPE.
- One and the same constant can be added to the siz and end attributes of all items of ORTHOTOPE.

Arg. properties
- Functional dependency: ORTHOTOPE.ori determined by ORTHOTOPE.siz and ORTHOTOPE.end.
- Functional dependency: ORTHOTOPE.siz determined by ORTHOTOPE.ori and ORTHOTOPE.end.
- Functional dependency: ORTHOTOPE.end determined by ORTHOTOPE.ori and ORTHOTOPE.siz.
- Contractible wrt. ORTHOTOPE.

Usage Used in the **Arc constraint(s)** slot for defining some constraints like DIFFN, PLACE_IN_PYRAMID or ORTHS_ARE_CONNECTED.

Used in DIFFN, ORTH_ON_THE_GROUND, ORTH_ON_TOP_OF_ORTH, ORTHS_ARE_CONNECTED, TWO_ORTH_ARE_IN_CONTACT, TWO_ORTH_COLUMN, TWO_ORTH_DO_NOT_OVERLAP, TWO_ORTH_INCLUDE.

Keywords **constraint arguments:** pure functional dependency.

constraint type: decomposition.

geometry: orthotope.

modelling: functional dependency.

Arc input(s)	ORTHOTOPE
Arc generator	$SELF \mapsto$ collection(orthotope)
Arc arity	1
Arc constraint(s)	orthotope.ori + orthotope.siz = orthotope.end
Graph property(ies)	$\mathbf{NARC}$= |ORTHOTOPE|

Graph model Parts (A) and (B) of Figure 5.670 respectively show the initial and final graph associated with the **Example** slot. Since we use the $\mathbf{NARC}$ graph property, the loops of the final graph are stressed in bold.

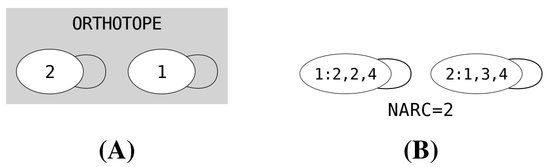

Figure 5.670: Initial and final graph of the ORTH_LINK_ORI_SIZ_END constraint

Signature Since we use the $SELF$ arc generator on the ORTHOTOPE collection the number of arcs of the initial graph is equal to |ORTHOTOPE|. Therefore the maximum number of arcs of the final graph is also equal to |ORTHOTOPE|. For this reason we can rewrite the graph property $\mathbf{NARC}$ = |ORTHOTOPE| to $\mathbf{NARC} \geq$ |ORTHOTOPE| and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.317 ORTH_ON_THE_GROUND

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Used for defining PLACE_IN_PYRAMID.

Constraint ORTH_ON_THE_GROUND(ORTHOTOPE, VERTICAL_DIM)

Arguments

ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)
VERTICAL_DIM : int

Restrictions

|ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori $\leq$ ORTHOTOPE.end
VERTICAL_DIM ≥ 1
VERTICAL_DIM $\leq$ |ORTHOTOPE|
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE)

Purpose The ori attribute of the VERTICAL_DIMth item of the ORTHOTOPES collection should be fixed to one.

Example (⟨ori − 1 siz − 2 end − 3, ori − 2 siz − 3 end − 5⟩ , 1)

The ORTH_ON_THE_GROUND constraint holds since the ori attribute of its 1^{th} item ⟨ori − 1 siz − 2 end − 3⟩ (i.e., 1^{th} item since VERTICAL_DIM $= 1$) is set to one.

Typical

|ORTHOTOPE| > 1
ORTHOTOPE.siz > 0

Used in PLACE_IN_PYRAMID.

Keywords **geometry:** geometrical constraint, orthotope.

Arc input(s)	ORTHOTOPE
Arc generator	*SELF* $\mapsto$ collection(orthotope)
Arc arity	1
Arc constraint(s)	• orthotope.key = VERTICAL_DIM • orthotope.ori = 1
Graph property(ies)	**NARC** = 1

Graph model Parts (A) and (B) of Figure 5.671 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the loop of the final graph is stressed in bold.

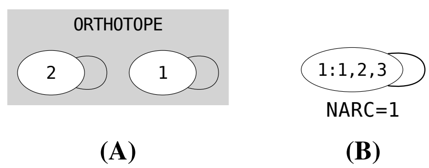

Figure 5.671: Initial and final graph of the ORTH_ON_THE_GROUND constraint

Signature Since all the key attributes of the ORTHOTOPES collection are distinct, because of the first condition of the arc constraint, and since we use the *SELF* arc generator the final graph contains at most one arc. Therefore we can rewrite the graph property **NARC** $=1$ to **NARC** ≥ 1 and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.318 ORTH_ON_TOP_OF_ORTH

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Used for defining PLACE_IN_PYRAMID.

Constraint ORTH_ON_TOP_OF_ORTH(ORTHOTOPE1, ORTHOTOPE2, VERTICAL_DIM)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Arguments

ORTHOTOPE1 : ORTHOTOPE
ORTHOTOPE2 : ORTHOTOPE
VERTICAL_DIM : int

Restrictions

$|\texttt{ORTHOTOPE}| > 0$
require_at_least(2, ORTHOTOPE, [ori, siz, end])
$\texttt{ORTHOTOPE.siz} \geq 0$
$\texttt{ORTHOTOPE.ori} \leq \texttt{ORTHOTOPE.end}$
$|\texttt{ORTHOTOPE1}| = |\texttt{ORTHOTOPE2}|$
$\texttt{VERTICAL\_DIM} \geq 1$
$\texttt{VERTICAL\_DIM} \leq |\texttt{ORTHOTOPE1}|$
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE1)
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE2)

Purpose

ORTHOTOPE1 is located on top of ORTHOTOPE2 which concretely means:

- In each dimension different from VERTICAL_DIM the projection of ORTHOTOPE1 is included in the projection of ORTHOTOPE2.
- In the dimension VERTICAL_DIM the origin of ORTHOTOPE1 coincide with the end of ORTHOTOPE2.

Example

$$\left(\begin{array}{l} \langle \texttt{ori}-5\ \texttt{siz}-2\ \texttt{end}-7, \texttt{ori}-3\ \texttt{siz}-3\ \texttt{end}-6 \rangle, \\ \langle \texttt{ori}-3\ \texttt{siz}-5\ \texttt{end}-8, \texttt{ori}-1\ \texttt{siz}-2\ \texttt{end}-3 \rangle, 2 \end{array} \right)$$

As illustrated by Figure 5.672 the orthotope ORTHOTOPE1 (rectangle R1 coloured in pink) is on top of ORTHOTOPE2 (rectangle R2 coloured in blue) according to the hypothesis that the vertical dimension corresponds to dimension 2 (i.e., $\texttt{VERTICAL\_DIM} = 2$). This stands from the fact that the following conditions hold:

- $\texttt{ORTHOTOPE2}[2].\texttt{ori} + \texttt{ORTHOTOPE2}[2].\texttt{siz} = 1 + 2 = \texttt{ORTHOTOPE1}[2].\texttt{ori}$,
- $\texttt{ORTHOTOPE2}[1].\texttt{ori} = 3 \leq \texttt{ORTHOTOPE1}[1].\texttt{ori} = 5$,
- $\texttt{ORTHOTOPE1}[1].\texttt{end} = 7 \leq \texttt{ORTHOTOPE2}[1].\texttt{end} = 8$.

Consequently, the ORTH_ON_TOP_OF_ORTH constraint holds.

Typical

$|\texttt{ORTHOTOPE}| > 1$
$\texttt{ORTHOTOPE.siz} > 0$

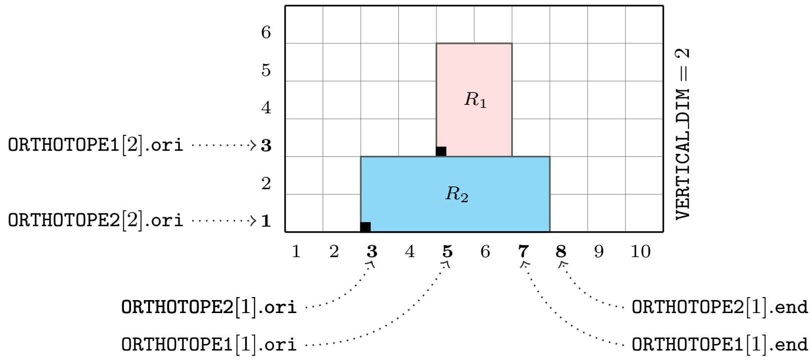

Figure 5.672: Illustration of the relation *on top of* of the **Example** slot (R_1 on top of R_2 wrt dimension VERTICAL_DIM $= 2$)

Used in PLACE_IN_PYRAMID.

Keywords **constraint type:** logic.

geometry: geometrical constraint, non-overlapping, orthotope.

Arc input(s)	ORTHOTOPE1 ORTHOTOPE2
Arc generator	$PRODUCT(=) \mapsto$collection(orthotope1, orthotope2)
Arc arity	2
Arc constraint(s)	• orthotope1.key $\neq$ VERTICAL_DIM • orthotope2.ori $\leq$ orthotope1.ori • orthotope1.end $\leq$ orthotope2.end
Graph property(ies)	**NARC**$= \lvert$ORTHOTOPE1$\rvert - 1$

Arc input(s)	ORTHOTOPE1 ORTHOTOPE2
Arc generator	$PRODUCT(=) \mapsto$collection(orthotope1, orthotope2)
Arc arity	2
Arc constraint(s)	• orthotope1.key $=$ VERTICAL_DIM • orthotope1.ori $=$ orthotope2.end
Graph property(ies)	**NARC**$= 1$

Graph model The first and second graph constraints respectively express the first and second conditions stated in the **Purpose** slot defining the ORTH_ON_TOP_OF_ORTH constraint.

Parts (A) and (B) of Figure 5.673 respectively show the initial and final graph associated with the second graph constraint of the **Example** slot. Since we use the **NARC** graph property, the unique arc of the final graph is stressed in bold.

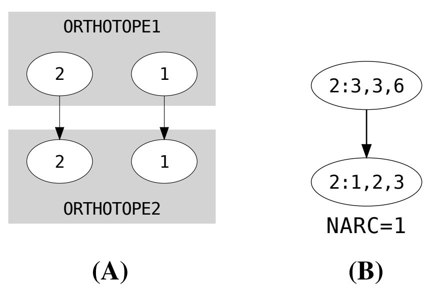

Figure 5.673: Initial and final graph of the ORTH_ON_TOP_OF_ORTH constraint

Signature Consider the second graph constraint. Since all the key attributes of the ORTHOTOPE1 collection are distinct, because of the arc constraint orthotope1.key $=$ VERTICAL_DIM, and since we use the $PRODUCT(=)$ arc generator the final graph contains at most one arc. Therefore we can rewrite the graph property **NARC** $= 1$ to **NARC** ≥ 1 and simplify $\underline{\mathbf{NARC}}$ to $\overline{\mathbf{NARC}}$.

5.319 ORTHS_ARE_CONNECTED

DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint ORTHS_ARE_CONNECTED(ORTHOTOPES)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Argument ORTHOTOPES : collection(orth − ORTHOTOPE)

Restrictions

$|\text{ORTHOTOPE}| > 0$
require_at_least(2, ORTHOTOPE, [ori, siz, end])
$\text{ORTHOTOPE.siz} > 0$
$\text{ORTHOTOPE.ori} \leq \text{ORTHOTOPE.end}$
required(ORTHOTOPES, orth)
same_size(ORTHOTOPES, orth)

Purpose

There should be a single group of connected orthotopes. Two orthotopes touch each other (i.e., are connected) if they overlap in all dimensions except one, and if, for the dimension where they do not overlap, the distance between the two orthotopes is equal to 0.

Example

$$\left(\left\langle\begin{array}{l}\text{orth} - \langle\text{ori} - 2\ \text{siz} - 4\ \text{end} - 6, \text{ori} - 2\ \text{siz} - 2\ \text{end} - 4\rangle,\\ \text{orth} - \langle\text{ori} - 1\ \text{siz} - 2\ \text{end} - 3, \text{ori} - 4\ \text{siz} - 3\ \text{end} - 7\rangle,\\ \text{orth} - \langle\text{ori} - 6\ \text{siz} - 3\ \text{end} - 9, \text{ori} - 1\ \text{siz} - 2\ \text{end} - 3\rangle,\\ \text{orth} - \langle\text{ori} - 6\ \text{siz} - 2\ \text{end} - 8, \text{ori} - 3\ \text{siz} - 2\ \text{end} - 5\rangle\end{array}\right\rangle\right)$$

Figure 5.674 shows the rectangles associated with the example. One can note that:

- Rectangle 2 touch rectangle 1,
- Rectangle 1 touch rectangle 2, rectangle 3 and rectangle 4,
- Rectangle 4 touch rectangle 1 and rectangle 3,
- Rectangle 3 touch rectangle 1 and rectangle 4.

Consequently, since we have a single group of connected rectangles, the ORTHS_ARE_CONNECTED constraint holds.

Typical

$|\text{ORTHOTOPE}| > 1$
$|\text{ORTHOTOPES}| > 1$

Symmetries

- Items of ORTHOTOPES are permutable.
- Items of ORTHOTOPES.orth are permutable (*same permutation used*).
- One and the same constant can be added to the ori and end attributes of all items of ORTHOTOPES.orth.

ORTHOTOPES (rectangles)

R_1:	$\langle \texttt{ori}-2\ \texttt{siz}-4\ \texttt{end}-6, \texttt{ori}-2\ \texttt{siz}-2\ \texttt{end}-4\rangle$
R_2:	$\langle \texttt{ori}-1\ \texttt{siz}-2\ \texttt{end}-3, \texttt{ori}-4\ \texttt{siz}-3\ \texttt{end}-7\rangle$
R_3:	$\langle \texttt{ori}-6\ \texttt{siz}-3\ \texttt{end}-9, \texttt{ori}-1\ \texttt{siz}-2\ \texttt{end}-3\rangle$
R_4:	$\langle \texttt{ori}-6\ \texttt{siz}-2\ \texttt{end}-8, \texttt{ori}-3\ \texttt{siz}-2\ \texttt{end}-5\rangle$

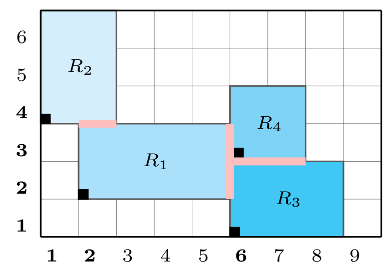

Figure 5.674: The four connected rectangles of the **Example** slot: contacts between rectangles are shown in pink

Usage In floor planning problem there is a typical constraint, that states that one should be able to access every room from any room.

See also **implies:** DIFFN.

used in graph description: ORTH_LINK_ORI_SIZ_END, TWO_ORTH_ARE_IN_CONTACT.

Keywords **geometry:** geometrical constraint, touch, contact, non-overlapping, orthotope.

Arc input(s)	ORTHOTOPES
Arc generator	$SELF \mapsto$ collection(orthotopes)
Arc arity	1
Arc constraint(s)	ORTH_LINK_ORI_SIZ_END(orthotopes.orth)
Graph property(ies)	**NARC**= |ORTHOTOPES|

Arc input(s)	ORTHOTOPES
Arc generator	$CLIQUE(\neq) \mapsto$ collection(orthotopes1, orthotopes2)
Arc arity	2
Arc constraint(s)	TWO_ORTH_ARE_IN_CONTACT(orthotopes1.orth, orthotopes2.orth)
Graph property(ies)	• **NVERTEX**= |ORTHOTOPES| • **NCC**= 1

Graph model Parts (A) and (B) of Figure 5.675 respectively show the initial and final graph associated with the **Example** slot.Since we use the **NVERTEX** graph property the vertices of the final graph are stressed in bold. Since we also use the **NCC** graph property we show the unique connected component of the final graph. An arc between two vertices indicates that two rectangles are in contact.

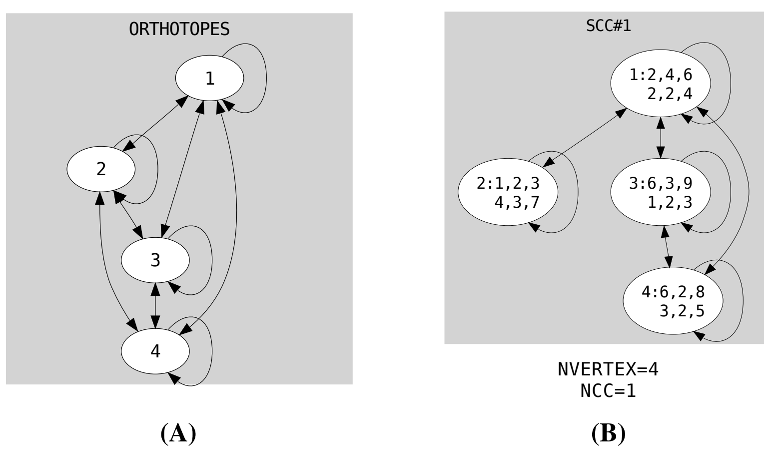

Figure 5.675: Initial and final graph of the ORTHS_ARE_CONNECTED constraint

Signature Since the first graph constraint uses the $SELF$ arc generator on the ORTHOTOPES collection the corresponding initial graph contains |ORTHOTOPES| arcs. Therefore the final graph of the first graph constraint contains at most |ORTHOTOPES| arcs and we can rewrite **NARC** = |ORTHOTOPES| to **NARC** $\geq$ |ORTHOTOPES|. So we can simplify $\overline{\textbf{NARC}}$ to $\underline{\textbf{NARC}}$.

Consider now the second graph constraint. Since its corresponding initial graph contains |ORTHOTOPES| vertices, its final graph has a maximum number of vertices also equal to $|\texttt{ORTHOTOPES}|$. Therefore we can rewrite $\mathbf{NVERTEX} = |\texttt{ORTHOTOPES}|$ to $\mathbf{NVERTEX} \geq |\texttt{ORTHOTOPES}|$ and simplify $\overline{\underline{\mathbf{NVERTEX}}}$ to $\overline{\mathbf{NVERTEX}}$. From the graph property $\mathbf{NVERTEX} = |\texttt{ORTHOTOPES}|$ and from the restriction $|\texttt{ORTHOTOPES}| > 0$ the final graph is not empty. Therefore it contains at least one connected component. So we can rewrite $\mathbf{NCC} = 1$ to $\mathbf{NCC} \leq 1$ and simplify $\overline{\underline{\mathbf{NCC}}}$ to $\underline{\mathbf{NCC}}$.

5.320 OVERLAP_SBOXES

▶ ▷ ◁ ◀ DESCRIPTION LINKS LOGIC

Origin Geometry, derived from [349]

Constraint OVERLAP_SBOXES(K, DIMS, OBJECTS, SBOXES)

Synonym OVERLAP.

Types

VARIABLES	:	collection(v−dvar)
INTEGERS	:	collection(v−int)
POSITIVES	:	collection(v−int)

Arguments

K	:	int
DIMS	:	sint
OBJECTS	:	collection(oid−int, sid−dvar, x − VARIABLES)
SBOXES	:	collection(sid−int, t − INTEGERS, l − POSITIVES)

Restrictions

$|\mathtt{VARIABLES}| \geq 1$
$|\mathtt{INTEGERS}| \geq 1$
$|\mathtt{POSITIVES}| \geq 1$
required(VARIABLES, v)
$|\mathtt{VARIABLES}| = \mathtt{K}$
required(INTEGERS, v)
$|\mathtt{INTEGERS}| = \mathtt{K}$
required(POSITIVES, v)
$|\mathtt{POSITIVES}| = \mathtt{K}$
$\mathtt{POSITIVES.v} > 0$
$\mathtt{K} > 0$
$\mathtt{DIMS} \geq 0$
$\mathtt{DIMS} < \mathtt{K}$
increasing_seq(OBJECTS, [oid])
required(OBJECTS, [oid, sid, x])
$\mathtt{OBJECTS.oid} \geq 1$
$\mathtt{OBJECTS.oid} \leq |\mathtt{OBJECTS}|$
$\mathtt{OBJECTS.sid} \geq 1$
$\mathtt{OBJECTS.sid} \leq |\mathtt{SBOXES}|$
$|\mathtt{SBOXES}| \geq 1$
required(SBOXES, [sid, t, l])
$\mathtt{SBOXES.sid} \geq 1$
$\mathtt{SBOXES.sid} \leq |\mathtt{SBOXES}|$
do_not_overlap(SBOXES)

Purpose

Holds if, for each pair of objects (O_i, O_j), $i < j$, O_i overlaps O_j with respect to a set of dimensions depicted by DIMS. O_i and O_j are objects that take a shape among a set of shapes. Each *shape* is defined as a finite set of shifted boxes, where each shifted box is described by a box in a K-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a *shifted box* is an entity defined by its shape id sid, shift offset t, and sizes l. Then, a shape is defined as the union of shifted boxes sharing the same shape id. An *object* is an entity defined by its unique object identifier oid, shape id sid and origin x.
An object O_i *overlaps* an object O_j with respect to a set of dimensions depicted by DIMS if and only if, there exists a shifted box s_i associated with O_i and there exists a shifted box s_j associated with O_j, such that (1) there exists a dimension $d \in$ DIMS where the end of O_i in dimension d is strictly greater than the start of O_j in dimension d, and (2) the end of O_j in dimension d is strictly greater than the start of O_i in dimension d.

Example

$$\left(\begin{array}{l} 2, \{0,1\}, \\ \left\langle\begin{array}{lll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 1,1\rangle, \\ \texttt{oid}-2 & \texttt{sid}-2 & \texttt{x}-\langle 3,2\rangle, \\ \texttt{oid}-3 & \texttt{sid}-3 & \texttt{x}-\langle 2,4\rangle \end{array}\right\rangle, \\ \left\langle\begin{array}{lll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 4,5\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 3,3\rangle, \\ \texttt{sid}-3 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,1\rangle \end{array}\right\rangle \end{array}\right)$$

Figure 5.676 shows the objects of the example. Since O_1 overlaps both O_2 and O_3, and since O_2 overlaps O_3, the OVERLAP_SBOXES constraint holds.

Typical

$|\texttt{OBJECTS}| > 1$

Symmetries

- Items of OBJECTS are permutable.
- Items of SBOXES are permutable.
- Items of OBJECTS.x, SBOXES.t and SBOXES.l are permutable (*same permutation used*).
- SBOXES.l.v can be increased.

Arg. properties

Suffix-contractible wrt. OBJECTS.

Remark

One of the eight relations of the *Region Connection Calculus* [349].

5.321 PATH

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from BINARY_TREE.

Constraint PATH(NPATH, NODES)

Arguments

NPATH : dvar
NODES : collection(index−int, succ−dvar)

Restrictions

$\texttt{NPATH} \geq 1$
$\texttt{NPATH} \leq |\texttt{NODES}|$
required(NODES, [index, succ])
$|\texttt{NODES}| > 0$
$\texttt{NODES.index} \geq 1$
$\texttt{NODES.index} \leq |\texttt{NODES}|$
distinct(NODES, index)
$\texttt{NODES.succ} \geq 1$
$\texttt{NODES.succ} \leq |\texttt{NODES}|$

Purpose

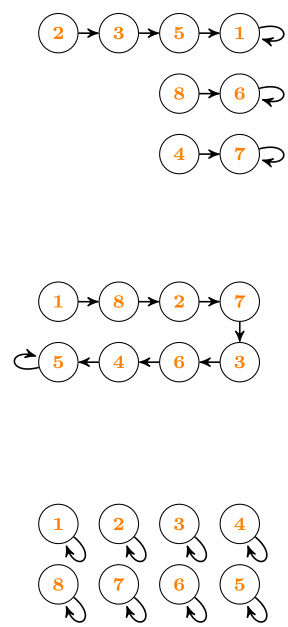
Cover the digraph G described by the NODES collection with NPATH paths in such a way that each vertex of G belongs to exactly one path.

Example

$$\left(\begin{array}{l} 3, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{succ}-1, \\ \texttt{index}-2 & \texttt{succ}-3, \\ \texttt{index}-3 & \texttt{succ}-5, \\ \texttt{index}-4 & \texttt{succ}-7, \\ \texttt{index}-5 & \texttt{succ}-1, \\ \texttt{index}-6 & \texttt{succ}-6, \\ \texttt{index}-7 & \texttt{succ}-7, \\ \texttt{index}-8 & \texttt{succ}-6 \end{array} \right\rangle \end{array}\right)$$

$$\left(\begin{array}{l} 1, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{succ}-8, \\ \texttt{index}-2 & \texttt{succ}-7, \\ \texttt{index}-3 & \texttt{succ}-6, \\ \texttt{index}-4 & \texttt{succ}-5, \\ \texttt{index}-5 & \texttt{succ}-5, \\ \texttt{index}-6 & \texttt{succ}-4, \\ \texttt{index}-7 & \texttt{succ}-3, \\ \texttt{index}-8 & \texttt{succ}-2 \end{array} \right\rangle \end{array}\right)$$

$$\left(\begin{array}{l} 8, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{succ}-1, \\ \texttt{index}-2 & \texttt{succ}-2, \\ \texttt{index}-3 & \texttt{succ}-3, \\ \texttt{index}-4 & \texttt{succ}-4, \\ \texttt{index}-5 & \texttt{succ}-5, \\ \texttt{index}-6 & \texttt{succ}-6, \\ \texttt{index}-7 & \texttt{succ}-7, \\ \texttt{index}-8 & \texttt{succ}-8 \end{array} \right\rangle \end{array}\right)$$



The first PATH constraint holds since its second argument corresponds to the 3 (i.e., the first argument of the PATH constraint) paths depicted by Figure 5.677.

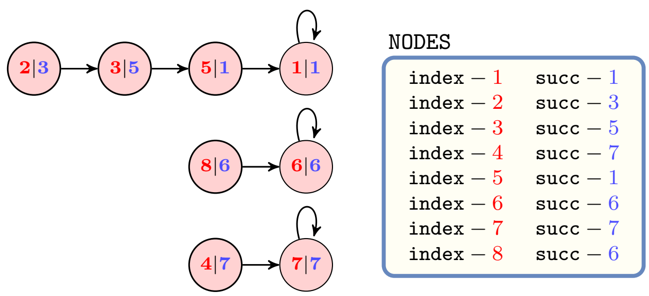


Figure 5.677: The three paths corresponding to the first example of the **Example** slot; each vertex contains the information `index`|`succ` where `succ` is the index of its successor in the path (by convention one of the extremities of a path points to itself).

All solutions

Figure 5.678 gives all solutions to the following non ground instance of the PATH constraint: NPATH $\in \{1,3\}$, $\mathtt{S}_1 \in [3,4]$, $\mathtt{S}_2 \in [1,2]$, $\mathtt{S}_3 \in [1,3]$, $\mathtt{S}_4 \in [2,4]$, PATH(NPATH, $\langle 1\ \mathtt{S}_1, 2\ \mathtt{S}_2, 3\ \mathtt{S}_3, 4\ \mathtt{S}_4\rangle$).

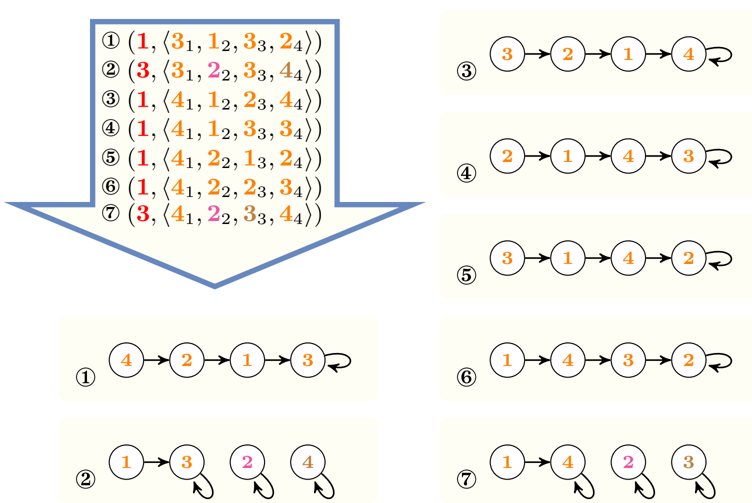

Figure 5.678: All solutions corresponding to the non ground example of the PATH constraint of the **All solutions** slot; in the left-hand side the `index` attributes are displayed as indices of the `succ` attribute, while in the right-hand side they are directly displayed within each node.

Typical

$\mathtt{NPATH} < |\mathtt{NODES}|$
$|\mathtt{NODES}| > 1$

Symmetry Items of NODES are permutable.

Arg. properties Functional dependency: NPATH determined by NODES.

Reformulation The PATH constraint can be expressed in term of (1) a set of $|\texttt{NODES}|^2$ reified constraints for avoiding circuit between more than one node and of (2) $|\texttt{NODES}|$ reified constraints and of one sum constraint for counting the paths and of (3) a set of $|\texttt{NODES}|^2$ reified constraints and of $|\texttt{NODES}|$ inequalities constraints for enforcing the fact that each vertex has at most two children.

1. For each vertex $\texttt{NODES}[i]$ $(i \in [1, |\texttt{NODES}|])$ of the NODES collection we create a variable R_i that takes its value within interval $[1, |\texttt{NODES}|]$. This variable represents the *rank* of vertex $\texttt{NODES}[i]$ within a solution. It is used to prevent the creation of circuit involving more than one vertex as explained now. For each pair of vertices $\texttt{NODES}[i], \texttt{NODES}[j]$ $(i, j \in [1, |\texttt{NODES}|])$ of the NODES collection we create a reified constraint of the form $\texttt{NODES}[i].\texttt{succ} = \texttt{NODES}[j].\texttt{index} \wedge i \neq j \Rightarrow R_i < R_j$. The purpose of this constraint is to express the fact that, if there is an arc from vertex $\texttt{NODES}[i]$ to another vertex $\texttt{NODES}[j]$, then R_i should be strictly less than R_j.

2. For each vertex $\texttt{NODES}[i]$ $(i \in [1, |\texttt{NODES}|])$ of the NODES collection we create a 0-1 variable B_i and state the following reified constraint $\texttt{NODES}[i].\texttt{succ} = \texttt{NODES}[i].\texttt{index} \Leftrightarrow B_i$ in order to force variable B_i to be set to value 1 if and only if there is a loop on vertex $\texttt{NODES}[i]$. Finally we create a constraint $\texttt{NPATH} = B_1 + B_2 + \cdots + B_{|\texttt{NODES}|}$ for stating the fact that the number of paths is equal to the number of loops of the graph.

3. For each pair of vertices $\texttt{NODES}[i], \texttt{NODES}[j]$ $(i, j \in [1, |\texttt{NODES}|])$ of the NODES collection we create a 0-1 variable B_{ij} and state the following reified constraint $\texttt{NODES}[i].\texttt{succ} = \texttt{NODES}[j].\texttt{index} \wedge i \neq j \Leftrightarrow B_{ij}$. Variable B_{ij} is set to value 1 if and only if there is an arc from $\texttt{NODES}[i]$ to $\texttt{NODES}[j]$. Then for each vertex $\texttt{NODES}[j]$ $(j \in [1, |\texttt{NODES}|])$ we create a constraint of the form $B_{1j} + B_{2j} + \cdots + B_{|\texttt{NODES}|j} \leq 1$.

A second reformulation of the PATH constraint in term of two TREE constraints and one INVERSE_EXCEPT_LOOP constraint is described in the **Usage** slot of the INVERSE_EXCEPT_LOOP constraint.

See also **common keyword:** CIRCUIT *(graph partitioning constraint, one_succ)*, DOM_REACHABILITY *(path)*, PATH_FROM_TO *(path, select an induced subgraph so that there is a path from a given vertex to an other given vertex)*, PROPER_CIRCUIT *(graph partitioning constraint, one_succ)*.

generalisation: BINARY_TREE *(at most one child replaced by at most two children)*, TEMPORAL_PATH *(vertices are located in time, and to each arc corresponds a precedence constraint)*, TREE *(at most one child replaced by no limit on the number of children)*.

implies: BINARY_TREE.

related: BALANCE_PATH *(counting number of paths versus controlling how balanced the paths are)*.

Keywords **combinatorial object:** path.

constraint type: graph constraint, graph partitioning constraint.

filtering: DFS-bottleneck.

final graph structure: connected component, tree, one_succ.

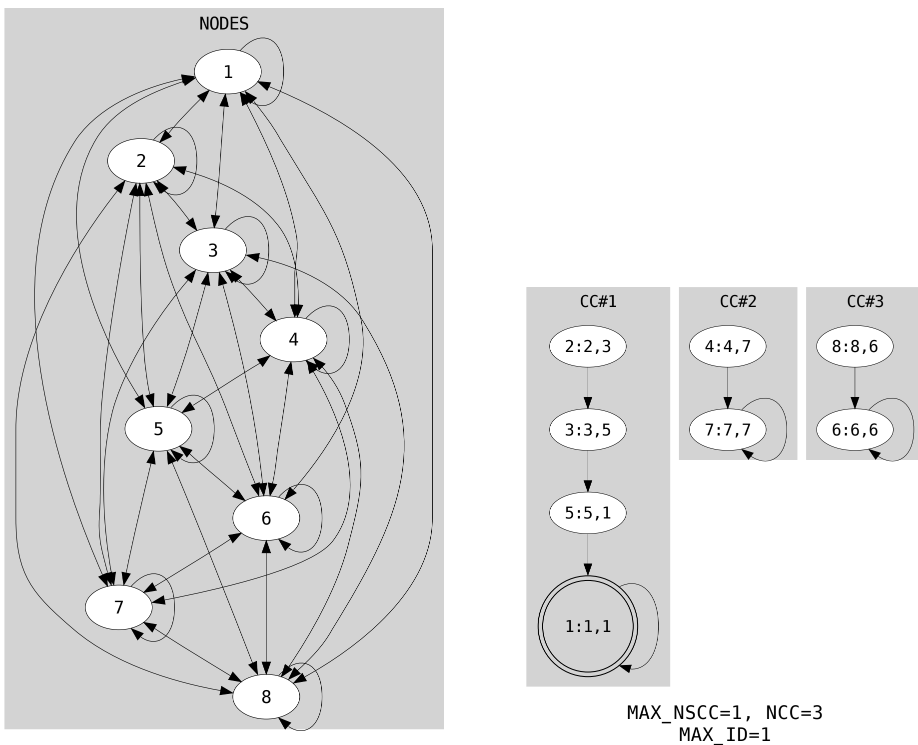
modelling: functional dependency.

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	nodes1.succ = nodes2.index
Graph property(ies)	• **MAX_NSCC** ≤ 1 • **NCC** = NPATH • **MAX_ID** ≤ 1
Graph class	ONE_SUCC

Graph model We use the same graph constraint as for the BINARY_TREE constraint, except that we replace the graph property **MAX_ID** ≤ 2, which constraints the maximum in-degree of the final graph to not exceed 2 by **MAX_ID** ≤ 1. **MAX_ID** does not consider loops: This is why we do not have any problem with the final node of each path.

Parts (A) and (B) of Figure 5.679 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **NCC** graph property, we display the three connected components of the final graph. Each of them corresponds to a path. Since we use the **MAX_ID** graph property, we also show with a double circle a vertex that has a maximum number of predecessors.

The PATH constraint holds since all strongly connected components of the final graph have no more than one vertex, since NPATH = **NCC** $= 3$ and since **MAX_ID** $= 1$.



(A) **(B)**

Figure 5.679: Initial and final graph of the PATH constraint

5.322 PATH_FROM_TO

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [6]

Constraint PATH_FROM_TO(FROM, TO, NODES)

Usual name PATH

Arguments

FROM : int
TO : int
NODES : collection(index−int, succ−svar)

Restrictions

FROM ≥ 1
FROM $\leq$ |NODES|
TO ≥ 1
TO $\leq$ |NODES|
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ $\leq$ |NODES|

Purpose Select some arcs of a digraph G so that there is still a path between two given vertices of G.

Example

$$\left(4, 3, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{succ}-\emptyset, \\ \texttt{index}-2 & \texttt{succ}-\emptyset, \\ \texttt{index}-3 & \texttt{succ}-\{5\}, \\ \texttt{index}-4 & \texttt{succ}-\{5\}, \\ \texttt{index}-5 & \texttt{succ}-\{2,3\} \end{array} \right\rangle \right)$$

The PATH_FROM_TO constraint holds since within the digraph G corresponding to the item of the NODES collection there is a path from vertex FROM $= 4$ to vertex TO $= 3$: this path starts from vertex 4, enters vertex 5, and ends up in vertex 3.

Typical

FROM $\neq$ TO
|NODES| > 2

Symmetry Items of NODES are permutable.

Remark Within [140] an undirected version of the PATH_FROM_TO constraint was proposed under the name UNDIRECTED_PATH.

See also

common keyword: DOM_REACHABILITY *(path)*, LINK_SET_TO_BOOLEANS *(constraint involving set variables)*, PATH, TEMPORAL_PATH *(path)*.

used in graph description: IN_SET.

Keywords

combinatorial object: path.

constraint arguments: constraint involving set variables.

constraint type: graph constraint.

filtering: linear programming.

Arc input(s)	NODES
Arc generator	*CLIQUE*↦collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	IN_SET(nodes2.index, nodes1.succ)
Graph property(ies)	**PATH_FROM_TO**(index, FROM, TO) = 1

Graph model Within the context of the **Example** slot, part (A) of Figure 5.680 shows the initial graph from which we choose to start. It is derived from the set associated with each vertex. Each set describes the potential values of the succ attribute of a given vertex. Part (B) of Figure 5.680 gives the final graph associated with the **Example** slot. Since we use the **PATH_FROM_TO** graph property we show on the final graph the following information:

- The vertices that respectively correspond to the start and the end of the required path are stressed in bold.
- The arcs on the required path are also stressed in bold.

The PATH_FROM_TO constraint holds since there is a path from vertex 4 to vertex 3 (4 and 3 refer to the index attribute of a vertex).

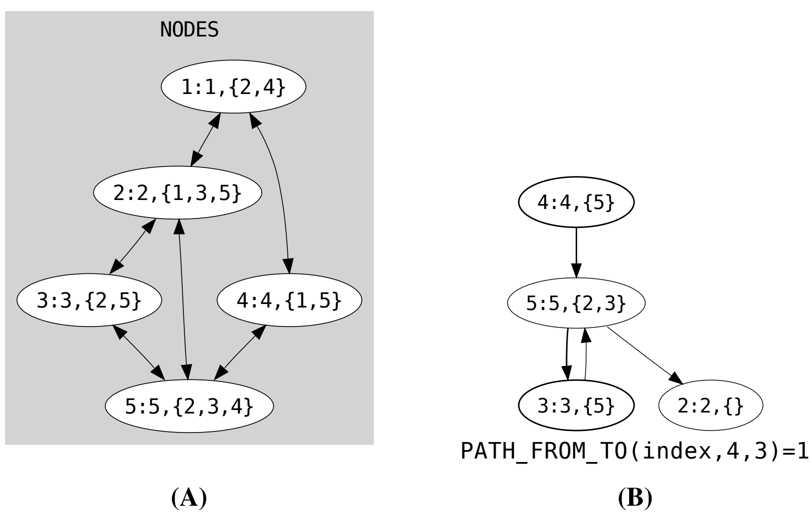


Figure 5.680: Initial and final graph of the PATH_FROM_TO set constraint

Signature Since the maximum value returned by the graph property **PATH_FROM_TO** is equal to 1 we can rewrite **PATH_FROM_TO**(index, FROM, TO) = 1 to **PATH_FROM_TO**(index, FROM, TO) ≥ 1. Therefore we simplify **PATH_FROM_TO** to **PATH_FROM_TO**.

5.323 PATTERN

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin [92]

Constraint $\text{PATTERN}(\mathtt{VARIABLES}, \mathtt{PATTERNS})$

Type $\mathtt{PATTERN} : \mathtt{collection}(\mathtt{var}-\mathtt{int})$

Arguments

$\mathtt{VARIABLES} : \mathtt{collection}(\mathtt{var}-\mathtt{dvar})$
$\mathtt{PATTERNS} : \mathtt{collection}(\mathtt{pat}-\mathtt{PATTERN})$

Restrictions

$\mathtt{required}(\mathtt{PATTERN}, \mathtt{var})$
$\mathtt{PATTERN.var} \geq 0$
$\text{CHANGE}(0, \mathtt{PATTERN}, =)$
$|\mathtt{PATTERN}| > 1$
$\mathtt{required}(\mathtt{VARIABLES}, \mathtt{var})$
$\mathtt{required}(\mathtt{PATTERNS}, \mathtt{pat})$
$|\mathtt{PATTERNS}| > 0$
$\mathtt{same\_size}(\mathtt{PATTERNS}, \mathtt{pat})$

Purpose

We quote the definition from the original article [92, page 157] introducing the PATTERN constraint:

> "*We call a k-pattern ($k > 1$) any sequence of k elements such that no two successive elements have the same value. Consider a set $V = \{v_1, v_2, \ldots, v_m\}$ and a sequence* $\mathbf{s} = s_1\ s_2\ \ldots\ s_n$ *of elements of V. In this context, a* stretch *is a maximum subsequence of variables of* $\mathbf{s}$ *which all have the same value. Consider now the sequence $v_{i1}\ v_{i2}\ \ldots\ v_{il}$ of the types of the successive stretches that appear in* $\mathbf{s}$*. Let $\mathcal{P}$ be a set of k-patterns.* $\mathbf{s}$ *satisfies $\mathcal{P}$ if and only if every subsequence of k elements in $v_{i1}\ v_{i2}\ \ldots, v_{il}$ belongs to $\mathcal{P}$.*"

Example

$$\left(\begin{array}{l}\langle 1,1,2,2,2,1,3,3\rangle, \\ \langle \mathtt{pat}-\langle 1,2,1\rangle, \mathtt{pat}-\langle 1,2,3\rangle, \mathtt{pat}-\langle 2,1,3\rangle\rangle\end{array}\right)$$

The PATTERN constraint holds since, as depicted by Figure 5.681, all its sequences of three consecutive stretches correspond to one of the 3-patterns given in the PATTERNS collection.

Typical

$|\mathtt{VARIABLES}| > 2$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 1$

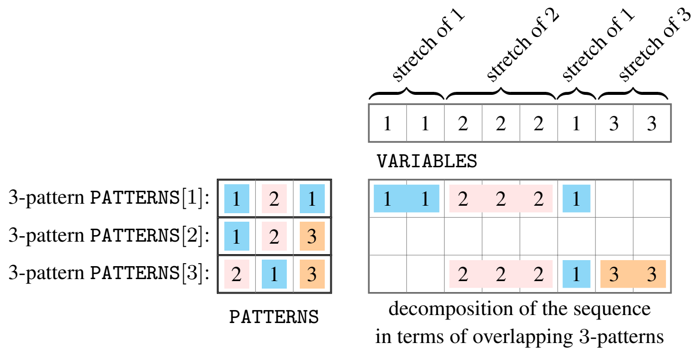

Figure 5.681: The sequence of the **Example** slot, its four stretches and the corresponding two 3-patterns 1 2 1 and 2 1 3

Symmetries

- Items of PATTERNS are permutable.
- Items of VARIABLES and PATTERNS.pat are simultaneously reversable.
- All occurrences of two distinct tuples of values in VARIABLES.var or PATTERNS.pat.var can be swapped; all occurrences of a tuple of values in VARIABLES.var or PATTERNS.pat.var can be renamed to any unused tuple of values.

Arg. properties

- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Usage

The PATTERN constraint was originally introduced within the context of staff scheduling. In this context, the value of the i^{th} variable of the VARIABLES collection corresponds to the type of shift performed by a person on the i^{th} day. A *stretch* is a maximum sequence of consecutive variables that are all assigned to the same value. The PATTERN constraint imposes that each sequence of k consecutive stretches belongs to a given list of patterns.

Remark

A generalisation of the PATTERN constraint to the REGULAR constraint enforcing the fact that a sequence of variables corresponds to a regular expression is presented in [317].

common keyword: GROUP *(timetabling constraint)*, SLIDING_DISTRIBUTION *(sliding sequence constraint)*, STRETCH_CIRCUIT, STRETCH_PATH *(sliding sequence constraint,timetabling constraint)*, STRETCH_PATH_PARTITION *(sliding sequence constraint)*.

Keywords

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: timetabling constraint, sliding sequence constraint.

filtering: arc-consistency.

Automaton Taking advantage that all k-patterns have the same length k, it is straightforward to construct an automaton that only accepts solutions of the PATTERN constraint. Figure 5.682 depicts the automaton associated with the PATTERN constraint of the **Example** slot. The construction can be done in three steps:

- First, build a prefix tree of all the k-patterns. In the context of our example, this gives all arcs of Figure 5.682, except self loops and the arc from s_3 to s_7.
- Second, find out the transitions that exit a leave of the tree. For this purpose we remove the first symbol of the corresponding k-pattern, add at the end of the remaining k-pattern a symbol corresponding to a stretch value, and check whether the new pattern belongs or not to the set of k-patterns of the PATTERN constraint. When the new pattern belongs to the set of k-patterns we add a corresponding transition. For instance, in the context of our example, consider the leave s_3 that is associated with the 3-pattern $1, 2, 1$. We remove the first symbol 1 and get $2, 1$. We then try to successively add the stretch values 1, 2 and 3 to the end of $2, 1$ and check if the corresponding patterns $2, 1, 1$, $2, 1, 2$ and $2, 1, 3$ belong or not to our set of 3-patterns. Since only $2, 1, 3$ is a 3-pattern we add a new transition between the corresponding leaves of the prefix tree (i.e., a transition from s_3 to s_7).
- Third, in order to take into account that each value of a k-pattern corresponds in fact to a given stretch value (i.e., several consecutive values that are assigned the same value), we add a self loop to all non-source states with a transition label that corresponds to the transition label of their entering arcs.

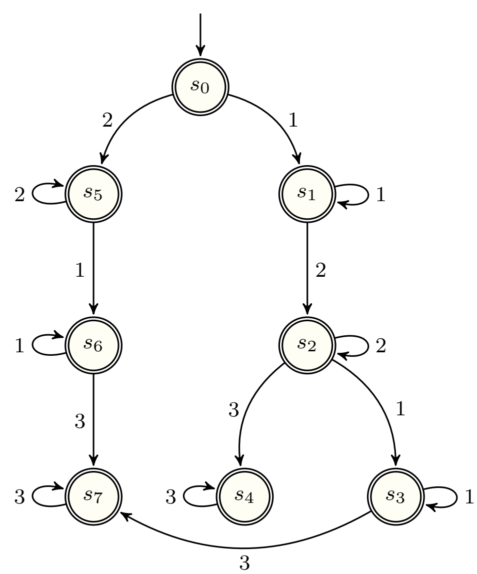

Figure 5.682: Automaton of the PATTERN constraint of the **Example** slot

5.324 PEAK

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin Derived from INFLEXION.

Constraint PEAK(N, VARIABLES)

Arguments

N : dvar
VARIABLES : collection(var−dvar)

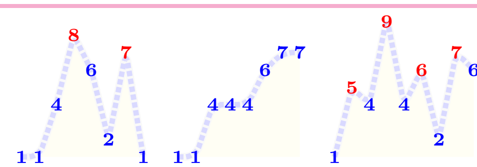
Restrictions

$\mathtt{N} \geq 0$
$2 * \mathtt{N} \leq \mathtt{max}(|\mathtt{VARIABLES}| - 1, 0)$
required(VARIABLES, var)

Purpose A variable V_k $(1 < k < m)$ of the sequence of variables $\mathtt{VARIABLES} = V_1, \ldots, V_m$ is a *peak* if and only if there exists an i (with $1 < i \leq k$) such that $V_{i-1} < V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k > V_{k+1}$. N is the total number of peaks of the sequence of variables VARIABLES.

Example

$(2, \langle 1, 1, 4, 8, 6, 2, 7, 1 \rangle)$
$(0, \langle 1, 1, 4, 4, 4, 6, 7, 7 \rangle)$
$(4, \langle 1, 5, 4, 9, 4, 6, 2, 7, 6 \rangle)$



The first PEAK constraint holds since the sequence 1 1 4 8 6 2 7 1 contains two peaks that respectively correspond to the variables that are assigned to values 8 and 7.

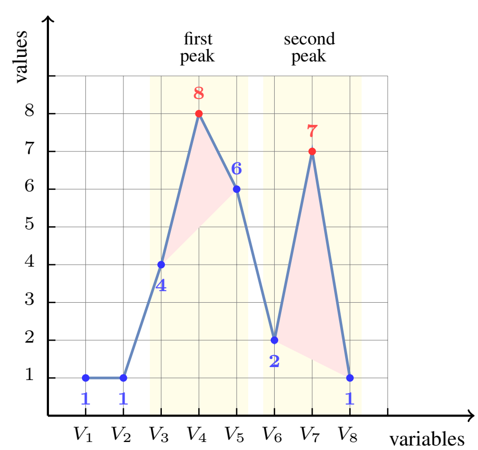


Figure 5.683: Illustration of the first example of the **Example** slot: a sequence of eight variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8 respectively fixed to values 1, 1, 4, 8, 6, 2, 7, 1 and its corresponding two peaks ($\mathtt{N} = 2$)

All solutions

Figure 5.684 gives all solutions to the following non ground instance of the PEAK constraint: $\mathtt{N} \in [1,2]$, $\mathtt{V}_1 \in [1,2]$, $\mathtt{V}_2 = 2$, $\mathtt{V}_3 \in [1,2]$, $\mathtt{V}_4 \in [1,2]$, $\mathtt{V}_5 \in [2,3]$, PEAK$(\mathtt{N}, \langle \mathtt{V}_1, \mathtt{V}_2, \mathtt{V}_3, \mathtt{V}_4, \mathtt{V}_5 \rangle)$.

① $(\mathbf{1}, \langle 1, \mathbf{2}, 1, 1, 2\rangle)$
② $(\mathbf{1}, \langle 1, \mathbf{2}, 1, 1, 3\rangle)$
③ $(\mathbf{1}, \langle 1, \mathbf{2}, 1, 2, 2\rangle)$
④ $(\mathbf{1}, \langle 1, \mathbf{2}, 1, 2, 3\rangle)$
⑤ $(\mathbf{1}, \langle 1, \mathbf{2}, \mathbf{2}, 1, 2\rangle)$
⑥ $(\mathbf{1}, \langle 1, \mathbf{2}, \mathbf{2}, 1, 3\rangle)$

Figure 5.684: All solutions corresponding to the non ground example of the PEAK constraint of the **All solutions** slot where each peak is coloured in orange

Typical

$|\mathtt{VARIABLES}| > 2$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 1$

Typical model

$\mathtt{nval}(\mathtt{VARIABLES.var}) > 2$

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

- Functional dependency: N determined by VARIABLES.
- Contractible wrt. VARIABLES when $\mathtt{N} = 0$.

Usage

Useful for constraining the number of *peaks* of a sequence of domain variables.

Remark

Since the arity of the arc constraint is not fixed, the PEAK constraint cannot be currently described with the graph-based representation. However, this would not hold anymore if we were introducing a slot that specifies how to merge adjacent vertices of the final graph.

specialisation: NO_PEAK *(the variable counting the number of peaks is set to* 0 *and removed)*.

Keywords

characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint arguments: reverse of a constraint, pure functional dependency.

constraint network structure: sliding cyclic(1) constraint network(2).

filtering: glue matrix.

modelling: functional dependency.

Cond. implications

- PEAK(N, VARIABLES)
  with $\mathtt{N} > 0$
  implies ATLEAST_NVALUE(NVAL, VARIABLES)
  when $\mathtt{NVAL} = 2$.
- PEAK(N, VARIABLES)
  implies INFLEXION(N, VARIABLES)
  when N = PEAK(VARIABLES.var)+VALLEY(VARIABLES.var).

Automaton Figure 5.685 depicts the automaton associated with the PEAK constraint. To each pair of consecutive variables $(\mathtt{VAR}_i, \mathtt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\mathtt{VAR}_i$, $\mathtt{VAR}_{i+1}$ and S_i: $(\mathtt{VAR}_i < \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 0) \wedge (\mathtt{VAR}_i = \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 1) \wedge (\mathtt{VAR}_i > \mathtt{VAR}_{i+1} \Leftrightarrow S_i = 2)$.

STATE SEMANTICS

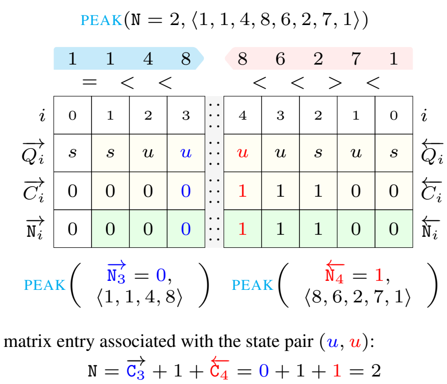

Figure 5.688: Illustrating the use of the state pair (u, u) of the glue matrix for linking N with the counters variables obtained after reading the prefix $1, 1, 4, 8$ and corresponding suffix $8, 6, 2, 7, 1$ of the sequence $1, 1, 4, 8, 6, 2, 7, 1$; note that the suffix $8, 6, 2, 7, 1$ (in pink) is proceed in reverse order; the left (resp. right) table shows the initialisation (for $i = 0$) and the evolution (for $i > 0$) of the state of the automaton and of its counter C upon reading the prefix $1, 1, 4, 8$ (resp. the suffix $1, 7, 2, 6, 8$).

5.325 PERIOD

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin N. Beldiceanu

Constraint PERIOD(PERIOD, VARIABLES, CTR)

Arguments

PERIOD : dvar
VARIABLES : collection(var−dvar)
CTR : atom

Restrictions

PERIOD ≥ 1
PERIOD $\leq |$VARIABLES$|$
required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose

Let us note $V_0, V_1, \ldots, V_{m-1}$ the variables of the VARIABLES collection. PERIOD is the *period* of the sequence $V_0\ V_1 \ldots V_{m-1}$ according to constraint CTR. This means that PERIOD is the smallest natural number such that V_i CTR $V_{i+\texttt{PERIOD}}$ holds for all $i \in 0, 1, \ldots, m - \texttt{PERIOD} - 1$.

Example

$(3, \langle 1, 1, 4, 1, 1, 4, 1, 1 \rangle, =)$

The PERIOD constraint holds since, as depicted by Figure 5.689, its first argument PERIOD $= 3$ is equal (i.e., since CTR is set to $=$) to the period of the sequence 1 1 4 1 1 4 1 1.

1	**1**	**4**	1	1	4	1	1

Figure 5.689: A sequence of period 3

Typical

PERIOD > 1
PERIOD $< |$VARIABLES$|$
$|$VARIABLES$| > 2$
range(VARIABLES.var) > 1
CTR $\in [=]$

Symmetries

- Items of VARIABLES can be reversed.
- Items of VARIABLES can be shifted.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties

- Functional dependency: PERIOD determined by VARIABLES and CTR.
- Contractible wrt. VARIABLES when CTR $\in [=]$ and PERIOD $= 1$.
- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Algorithm

When CTR corresponds to the equality constraint, a potentially incomplete filtering algorithm based on 13 deductions rules is described in [60]. The generalisation of these rules to the case where CTR is not the equality constraint is discussed.

See also

generalisation: PERIOD_VECTORS *(*variable *replaced by vector)*.

implies: PERIOD_EXCEPT_0.

soft variant: PERIOD_EXCEPT_0 *(value* 0 *can match any other value)*.

Keywords

combinatorial object: periodic, sequence.

constraint arguments: pure functional dependency.

constraint type: predefined constraint, timetabling constraint, scheduling constraint.

filtering: border.

modelling: functional dependency.

5.326 PERIOD_EXCEPT_0

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin

Derived from PERIOD.

Constraint

PERIOD_EXCEPT_0(PERIOD, VARIABLES, CTR)

Arguments

PERIOD	:	dvar
VARIABLES	:	collection(var−dvar)
CTR	:	atom

Restrictions

PERIOD ≥ 1
PERIOD $\leq$ |VARIABLES|
required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose

Let us note $V_0, V_1, \ldots, V_{m-1}$ the variables of the VARIABLES collection. PERIOD is the *period* of the sequence $V_0\ V_1 \ldots V_{m-1}$ according to constraint CTR. This means that PERIOD is the smallest natural number such that V_i CTR $V_{i+\texttt{PERIOD}} \vee V_i = 0 \vee V_{i+\texttt{PERIOD}} = 0$ holds for all $i \in 0, 1, \ldots, m - \texttt{PERIOD} - 1$.

Example

$(3, \langle 1, 1, 4, 1, 1, 0, 1, 1 \rangle, =)$

The PERIOD_EXCEPT_0 constraint holds since, as depicted by Figure 5.690, its first argument PERIOD $= 3$ is equal (i.e., since CTR is set to $=$) to the period of the sequence 1 1 4 1 1 0 1 1; value 0 is assumed to be equal to any other value.

Figure 5.690: A sequence that has a period of 3 when we assume that value 0 can match to any other value

Typical

PERIOD > 1
PERIOD $<$ |VARIABLES|
|VARIABLES| > 2
range(VARIABLES.var) > 1
ATLEAST(1, VARIABLES, 0)
CTR $\in [=]$

Typical model

ATLEAST(2, VARIABLES, 0)

Symmetries

- Items of VARIABLES can be reversed.
- Items of VARIABLES can be shifted.
- All occurrences of two distinct values of VARIABLES.var that are both different from 0 can be swapped; all occurrences of a value of VARIABLES.var that is different from 0 can be renamed to any unused value that is also different from 0.

Arg. properties

- Functional dependency: PERIOD determined by VARIABLES and CTR.
- Contractible wrt. VARIABLES when CTR $\in [=]$ and PERIOD $= 1$.
- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Usage

Useful for timetabling problems where a person should repeat some work pattern over an over except when he is unavailable for some reason. The value 0 represents the fact that he is unavailable, while the other values are used in the work pattern.

Algorithm

See [60].

5.327 PERIOD_VECTORS

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin

Derived from PERIOD

Constraint

PERIOD_VECTORS(PERIOD, VECTORS, CTRS)

Types

VECTOR	:	collection(var−dvar)
CTR	:	atom

Arguments

PERIOD	:	dvar
VECTORS	:	collection(vec − VECTOR)
CTRS	:	collection(ctr − CTR)

Restrictions

$|\mathtt{VECTOR}| \geq 1$
required(VECTOR, var)
$\mathtt{CTR} \in [=, \neq, <, \geq, >, \leq]$
$\mathtt{PERIOD} \geq 1$
$\mathtt{PERIOD} \leq |\mathtt{VECTORS}|$
required(VECTORS, vec)
same_size(VECTORS, vec)
required(CTRS, ctr)
$|\mathtt{CTRS}| = |\mathtt{VECTOR}|$

Purpose

Let us note $\mathtt{VECTOR}_0, \mathtt{VECTOR}_1, \ldots, \mathtt{VECTOR}_{n-1}$ the vectors of the VECTORS collection, and d the number of components of each vector (all vectors have the same size). PERIOD is the *period* of the sequence of vectors $\mathtt{VECTOR}_0, \mathtt{VECTOR}_1, \ldots, \mathtt{VECTOR}_{n-1}$ according to constraints CTRS. This means that PERIOD is the smallest natural number such that $\forall i \in [0, n - \mathtt{PERIOD} - 1], \forall j \in [0, d - 1]$: $\mathtt{VECTOR}_i.\mathtt{vec}[j]\ \mathtt{CTRS}[j]\ \mathtt{VECTOR}_{i+\mathtt{PERIOD}}.\mathtt{vec}[j]$.

Example

$$\left(\begin{array}{l} 3, \left\langle\begin{array}{l} \mathtt{vec} - \langle 1,0\rangle, \\ \mathtt{vec} - \langle 1,5\rangle, \\ \mathtt{vec} - \langle 4,4\rangle, \\ \mathtt{vec} - \langle 1,0\rangle, \\ \mathtt{vec} - \langle 1,5\rangle, \\ \mathtt{vec} - \langle 4,4\rangle, \\ \mathtt{vec} - \langle 1,0\rangle, \\ \mathtt{vec} - \langle 1,5\rangle \end{array}\right\rangle, \\ \langle =, = \rangle \end{array}\right)$$

The PERIOD_VECTORS constraint holds since its first argument $\mathtt{PERIOD} = 3$ is equal (i.e., since CTRS is set to $\langle =, = \rangle$) to the period of the sequence $\mathtt{vec} - \langle 1,0\rangle$, $\mathtt{vec} - \langle 1,5\rangle$, $\mathtt{vec} - \langle 4,4\rangle$, $\mathtt{vec} - \langle 1,0\rangle$, $\mathtt{vec} - \langle 1,5\rangle$, $\mathtt{vec} - \langle 4,4\rangle$, $\mathtt{vec} - \langle 1,0\rangle$, $\mathtt{vec} - \langle 1,5\rangle$.

Typical

$\mathtt{CTR} \in [=]$
$|\mathtt{VECTOR}| > 1$
$\mathtt{PERIOD} > 1$
$\mathtt{PERIOD} < |\mathtt{VECTORS}|$
$|\mathtt{VECTORS}| > 2$

Symmetry

Items of VECTORS can be reversed.

Arg. properties

- Functional dependency: PERIOD determined by VECTORS and CTRS.
- Prefix-contractible wrt. VECTORS.
- Suffix-contractible wrt. VECTORS.

See also

specialisation: PERIOD (*vector replaced by* variable).

Keywords

characteristic of a constraint: vector.

combinatorial object: periodic, sequence.

constraint arguments: pure functional dependency.

constraint type: predefined constraint.

modelling: functional dependency.

5.328 PERMUTATION

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from ALLDIFFERENT_CONSECUTIVE_VALUES.

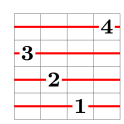
Constraint PERMUTATION(VARIABLES)

Argument VARIABLES : collection(var−dvar)

Restrictions
required(VARIABLES, var)
$\text{minval}(\texttt{VARIABLES.var}) = 1$
$\text{maxval}(\texttt{VARIABLES.var}) = |\texttt{VARIABLES}|$

Purpose Enforce all variables of the collection VARIABLES to take distinct values between 1 and the total number of variables.

Example $(\langle 3, 2, 1, 4\rangle)$



The PERMUTATION constraint holds since all the values 3, 2, 1 and 4 are distinct, and since they all belong to interval $[1, 4]$ where 4 is the total number of variables.

Typical $|\texttt{VARIABLES}| > 2$

Symmetries

- Items of VARIABLES are permutable.
- Two distinct values of VARIABLES.var can be swapped.

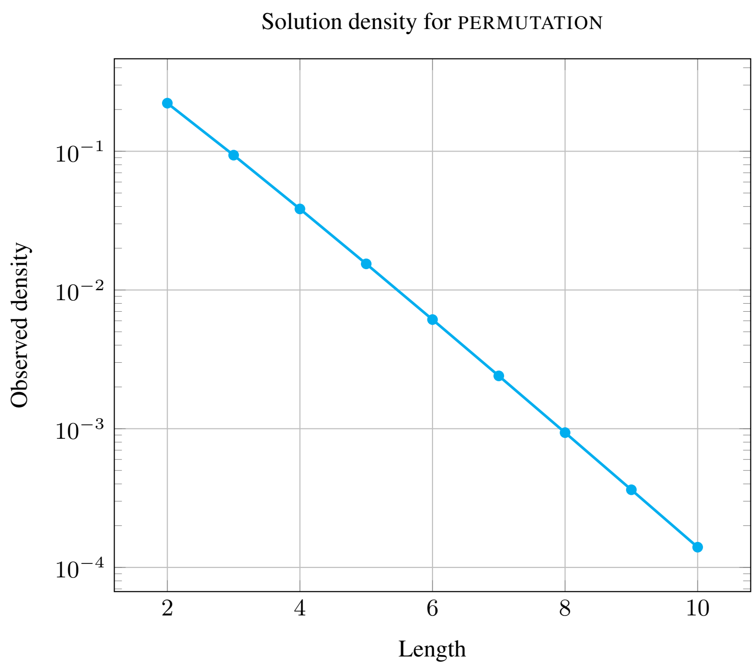
Usage See **Usage** slot of ALLDIFFERENT.

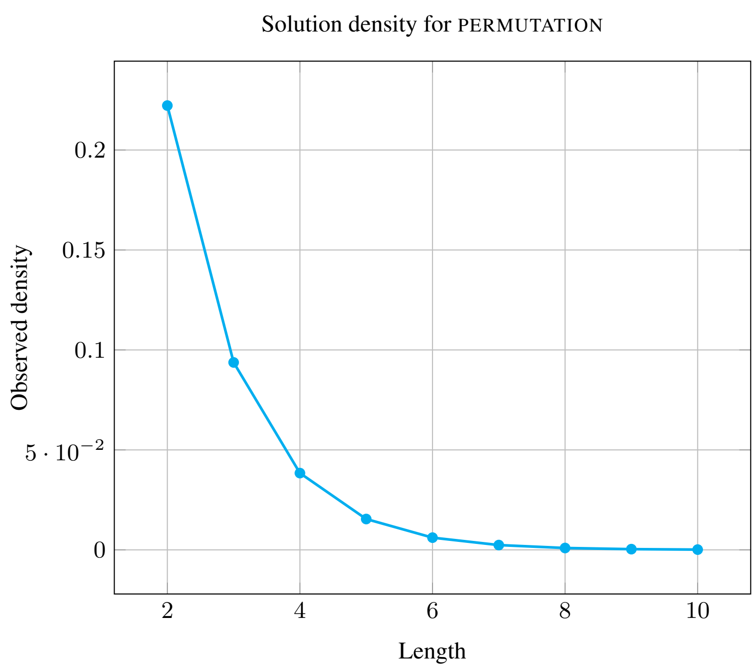
Algorithm See **Algorithm** slot of ALLDIFFERENT.

Counting

Length (n)	2	3	4	5	6	7	8	9	10
Solutions	2	6	24	120	720	5040	40320	362880	3628800

Number of solutions for PERMUTATION: domains $0..n$





See also **implied by:** PROPER_CIRCUIT.

implies: ALLDIFFERENT_CONSECUTIVE_VALUES.

Keywords **characteristic of a constraint:** all different, disequality, sort based reformulation.

combinatorial object: permutation.

constraint type: value constraint.

final graph structure: one_succ.

Cond. implications

  and first(VARIABLES.var) $<$maxval(VARIABLES.var)
  and last(VARIABLES.var) $<$maxval(VARIABLES.var)
  implies HIGHEST_PEAK(HEIGHT, VARIABLES)
  when HEIGHT $=$maxval(VARIABLES.var).

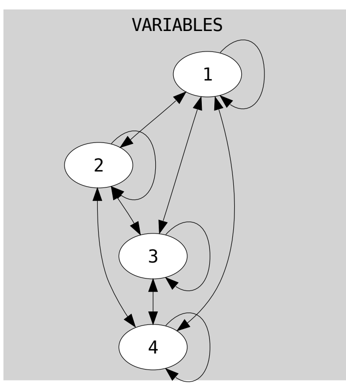
- PERMUTATION(VARIABLES)
  with |VARIABLES| $>$ 2
  and first(VARIABLES.var) $=$ |VARIABLES|
  implies HIGHEST_PEAK(HEIGHT, VARIABLES)
  when HEIGHT $=$ |VARIABLES| $-$ 1.

- PERMUTATION($\texttt{VARIABLES}$)
  with $|\texttt{VARIABLES}| > 2$
  and $\texttt{last}(\texttt{VARIABLES.var}) = |\texttt{VARIABLES}|$
  implies HIGHEST_PEAK($\texttt{HEIGHT}, \texttt{VARIABLES}$)
  when $\texttt{HEIGHT} = |\texttt{VARIABLES}| - 1$.

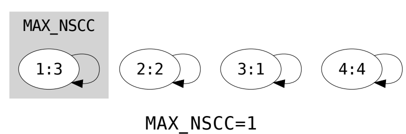
Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**MAX_NSCC** ≤ 1
Graph class	ONE_SUCC

Graph model We generate a *clique* with an *equality* constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed one. Finally the restrictions express the fact that all values are between 1 and the total number of variables.

Parts (A) and (B) of Figure 5.691 respectively show the initial and final graph associated with the **Example** slot. Since we use the **MAX_NSCC** graph property we show one of the largest strongly connected component of the final graph. The PERMUTATION holds since all the strongly connected components have at most one vertex: a value is used at most once.



(A)



(B)

Figure 5.691: Initial and final graph of the PERMUTATION constraint

5.329 PLACE_IN_PYRAMID

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint PLACE_IN_PYRAMID(ORTHOTOPES, VERTICAL_DIM)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Arguments

ORTHOTOPES : collection(orth − ORTHOTOPE)
VERTICAL_DIM : int

Restrictions

|ORTHOTOPE| >0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori $\leq$ ORTHOTOPE.end
required(ORTHOTOPES, orth)
same_size(ORTHOTOPES, orth)
VERTICAL_DIM ≥ 1
DIFFN(ORTHOTOPES)

Purpose

For each pair of orthotopes (O_1, O_2) of the collection ORTHOTOPES, O_1 and O_2 do not overlap (two orthotopes do not overlap if there exists at least one dimension where their projections do not overlap). In addition, each orthotope of the collection ORTHOTOPES should be supported by one other orthotope or by the ground. The vertical dimension is given by the parameter VERTICAL_DIM.

Example

$$\left(\left\langle\begin{array}{l}\texttt{orth}-\langle\texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4, \texttt{ori}-1\ \texttt{siz}-2\ \texttt{end}-3\rangle,\\ \texttt{orth}-\langle\texttt{ori}-1\ \texttt{siz}-2\ \texttt{end}-3, \texttt{ori}-3\ \texttt{siz}-3\ \texttt{end}-6\rangle,\\ \texttt{orth}-\left\langle\begin{array}{lll}\texttt{ori}-5 & \texttt{siz}-6 & \texttt{end}-11,\\ \texttt{ori}-1 & \texttt{siz}-2 & \texttt{end}-3\end{array}\right\rangle,\\ \texttt{orth}-\langle\texttt{ori}-5\ \texttt{siz}-2\ \texttt{end}-7, \texttt{ori}-3\ \texttt{siz}-2\ \texttt{end}-5\rangle,\\ \texttt{orth}-\left\langle\begin{array}{lll}\texttt{ori}-8 & \texttt{siz}-3 & \texttt{end}-11,\\ \texttt{ori}-3 & \texttt{siz}-2 & \texttt{end}-5\end{array}\right\rangle,\\ \texttt{orth}-\left\langle\begin{array}{lll}\texttt{ori}-8 & \texttt{siz}-2 & \texttt{end}-10,\\ \texttt{ori}-5 & \texttt{siz}-2 & \texttt{end}-7\end{array}\right\rangle\end{array}\right\rangle, 2\right)$$

Figure 5.692 depicts the placement associated with the example, where the i^{th} item of the ORTHOTOPES collection is represented by the rectangle Ri. The PLACE_IN_PYRAMID constraint holds since the rectangles do not overlap and since rectangles R1, R2, R3, R4, R5, and R6 are respectively supported by the ground, R1, the ground, R3, R3, and R5.

Typical

|ORTHOTOPE| >1
ORTHOTOPE.siz >0
|ORTHOTOPES| >1

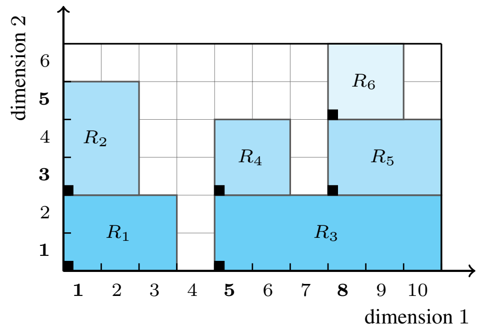


Figure 5.692: Solution corresponding to the **Example** slot

Symmetry Items of `ORTHOTOPES` are permutable.

Usage The DIFFN constraint is not enough if one wants to produce a placement where no orthotope floats in the air. This constraint is usually handled with a heuristic during the enumeration phase.

See also **used in graph description:** ORTH_ON_THE_GROUND, ORTH_ON_TOP_OF_ORTH.

Keywords **constraint type:** logic.

geometry: geometrical constraint, non-overlapping, orthotope.

Arc input(s) ORTHOTOPES

Arc generator $CLIQUE \mapsto$ collection(orthotopes1, orthotopes2)

Arc arity 2

Arc constraint(s)

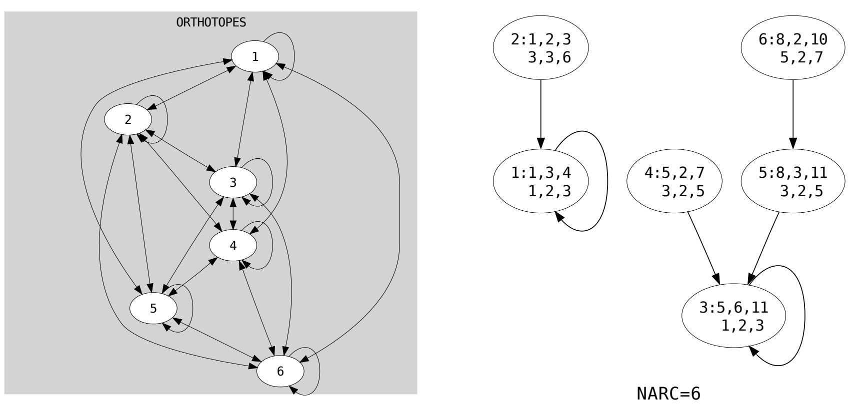
$$\bigvee\left(\begin{array}{l}\bigwedge\left(\begin{array}{l}\texttt{orthotopes1.key} = \texttt{orthotopes2.key},\\ \texttt{ORTH\_ON\_THE\_GROUND}(\texttt{orthotopes1.orth}, \texttt{VERTICAL\_DIM})\end{array}\right),\\ \bigwedge\left(\begin{array}{l}\texttt{orthotopes1.key} \neq \texttt{orthotopes2.key},\\ \texttt{ORTH\_ON\_TOP\_OF\_ORTH}\left(\begin{array}{l}\texttt{orthotopes1.orth},\\ \texttt{orthotopes2.orth},\\ \texttt{VERTICAL\_DIM}\end{array}\right)\end{array}\right)\end{array}\right)$$

Graph property(ies) $\mathbf{NARC} = |\texttt{ORTHOTOPES}|$

Graph model The arc constraint of the graph constraint forces one of the following conditions:

- If the arc connects the same orthotope O then the ground directly supports O,
- Otherwise, if we have an arc from an orthotope O_1 to a distinct orthotope O_2, the condition is: O_1 is on top of O_2 (i.e., in all dimensions, except dimension VERTICAL_DIM, the projection of O_1 is included in the projection of O_2, while in dimension VERTICAL_DIM the projection of O_1 is located after the projection of O_2).

Parts (A) and (B) of Figure 5.693 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.



(A) **(B)**

Figure 5.693: Initial and final graph of the PLACE_IN_PYRAMID constraint

5.330 POLYOMINO

DESCRIPTION LINKS GRAPH

Origin

Inspired by [206].

Constraint

POLYOMINO($\texttt{CELLS}$)

Argument

$$\texttt{CELLS} : \texttt{collection}\begin{pmatrix}\texttt{index}-\texttt{int},\\ \texttt{right}-\texttt{dvar},\\ \texttt{left}-\texttt{dvar},\\ \texttt{up}-\texttt{dvar},\\ \texttt{down}-\texttt{dvar}\end{pmatrix}$$

Restrictions

$\texttt{CELLS.index} \geq 1$
$\texttt{CELLS.index} \leq |\texttt{CELLS}|$
$|\texttt{CELLS}| \geq 1$
$\texttt{required}(\texttt{CELLS}, [\texttt{index}, \texttt{right}, \texttt{left}, \texttt{up}, \texttt{down}])$
$\texttt{distinct}(\texttt{CELLS}, \texttt{index})$
$\texttt{CELLS.right} \geq 0$
$\texttt{CELLS.right} \leq |\texttt{CELLS}|$
$\texttt{CELLS.left} \geq 0$
$\texttt{CELLS.left} \leq |\texttt{CELLS}|$
$\texttt{CELLS.up} \geq 0$
$\texttt{CELLS.up} \leq |\texttt{CELLS}|$
$\texttt{CELLS.down} \geq 0$
$\texttt{CELLS.down} \leq |\texttt{CELLS}|$

Purpose

Enforce all cells of the collection CELLS to be connected and to form a single block. Each cell is defined by the following attributes:

1. The index attribute of the cell, which is an integer between 1 and the total number of cells, is unique for each cell.
2. The right attribute that is the index of the cell located immediately to the right of that cell (or 0 if no such cell exists).
3. The left attribute that is the index of the cell located immediately to the left of that cell (or 0 if no such cell exists).
4. The up attribute that is the index of the cell located immediately on top of that cell (or 0 if no such cell exists).
5. The down attribute that is the index of the cell located immediately above that cell (or 0 if no such cell exists).

This corresponds to a polyomino [206].

Example

$$\left(\left\langle\begin{array}{lllll}\texttt{index}-1 & \texttt{right}-0 & \texttt{left}-0 & \texttt{up}-2 & \texttt{down}-0,\\ \texttt{index}-2 & \texttt{right}-3 & \texttt{left}-0 & \texttt{up}-0 & \texttt{down}-1,\\ \texttt{index}-3 & \texttt{right}-0 & \texttt{left}-2 & \texttt{up}-4 & \texttt{down}-0,\\ \texttt{index}-4 & \texttt{right}-5 & \texttt{left}-0 & \texttt{up}-0 & \texttt{down}-3,\\ \texttt{index}-5 & \texttt{right}-0 & \texttt{left}-4 & \texttt{up}-0 & \texttt{down}-0\end{array}\right\rangle\right)$$

The POLYOMINO constraint holds since all the cells corresponding to the items of the CELLS collection form one single group of connected cells: the i^{th} ($i \in [1, 4]$) cell is connected to the $(i+1)^{th}$ cell. Figure 5.694 shows the corresponding polyomino.

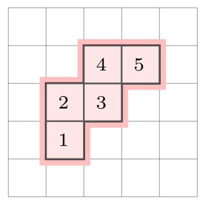


Figure 5.694: Polyomino corresponding to the **Example** slot where each cell contains the index of the corresponding item within the CELLS collection

Symmetries

- Items of CELLS are permutable.
- Attributes of CELLS are permutable w.r.t. permutation (index) (right, left) (up) (down) (*permutation applied to all items*).
- Attributes of CELLS are permutable w.r.t. permutation (index) (right) (left) (up, down) (*permutation applied to all items*).
- Attributes of CELLS are permutable w.r.t. permutation (index) (up, left, down, right) (*permutation applied to all items*).

Usage

Enumeration of polyominoes.

Keywords

combinatorial object: pentomino.

final graph structure: strongly connected component.

geometry: geometrical constraint.

puzzles: pentomino.

Arc input(s) CELLS

Arc generator $CLIQUE(\neq) \mapsto$ collection(cells1, cells2)

Arc arity 2

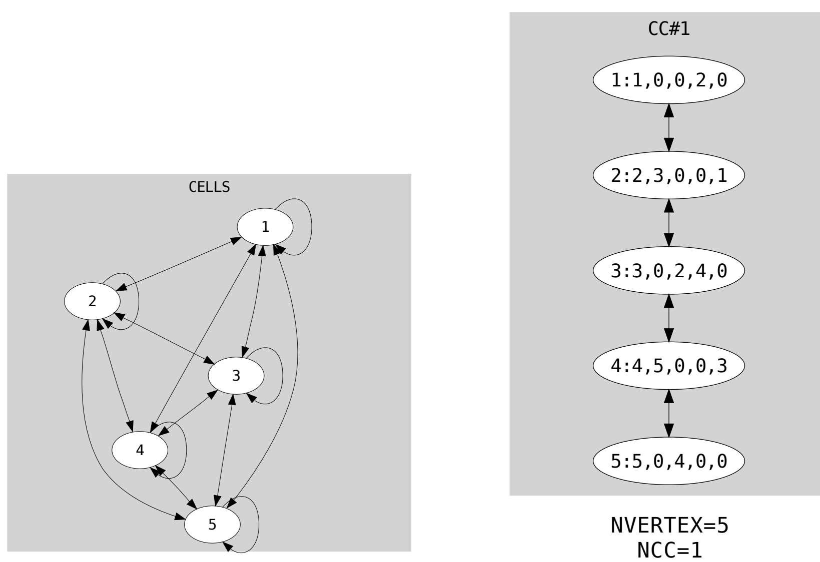
Arc constraint(s)

$$\bigvee\left(\begin{array}{l}\bigwedge\left(\begin{array}{l}\texttt{cells1.right} = \texttt{cells2.index},\\ \texttt{cells2.left} = \texttt{cells1.index}\end{array}\right),\\ \bigwedge\left(\begin{array}{l}\texttt{cells1.left} = \texttt{cells2.index},\\ \texttt{cells2.right} = \texttt{cells1.index}\end{array}\right),\\ \texttt{cells1.up} = \texttt{cells2.index} \wedge \texttt{cells2.down} = \texttt{cells1.index},\\ \texttt{cells1.down} = \texttt{cells2.index} \wedge \texttt{cells2.up} = \texttt{cells1.index}\end{array}\right)$$

Graph property(ies)
- **NVERTEX**$= |\texttt{CELLS}|$
- **NCC**$= 1$

Graph model The graph constraint models the fact that all the cells are connected. We use the $CLIQUE(\neq)$ arc generator in order to only consider connections between two distinct cells. The first graph property $\mathbf{NVERTEX} = |\texttt{CELLS}|$ avoid the case isolated cells, while the second graph property $\mathbf{NCC} = 1$ enforces to have a single group of connected cells.

Parts (A) and (B) of Figure 5.695 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NVERTEX** graph property the vertices of the final graph are stressed in bold. Since we also use the **NCC** graph property we show the unique connected component of the final graph. An arc between two vertices indicates that two cells are directly connected.



(A) **(B)**

Figure 5.695: Initial and final graph of the POLYOMINO constraint

Signature From the graph property $\mathbf{NVERTEX} = |\texttt{CELLS}|$ and from the restriction $|\texttt{CELLS}| \geq 1$ we have that the final graph is not empty. Therefore it contains at least one connected component. So we can rewrite $\mathbf{NCC} = 1$ to $\mathbf{NCC} \leq 1$ and simplify $\overline{\underline{\mathbf{NCC}}}$ to $\overline{\mathbf{NCC}}$.

5.331 POWER

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin [146]

Constraint POWER(X, N, Y)

Synonym XEXPYEQZ.

Arguments

X : dvar
N : dvar
Y : dvar

Restrictions

$X \geq 0$
$N \geq 0$
$Y \geq 0$

Purpose Enforce the fact that Y is equal to X^N.

Example $(2, 3, 8)$

The POWER constraint holds since 8 is equal to 2^3.

Typical

$X > 1$
$N > 1$
$N < 5$
$Y > 1$

Arg. properties Functional dependency: Y determined by X and N.

Algorithm In [146] a filtering algorithm for the POWER constraint was automatically derived from the algorithm that multiplies X by itself N times by using constructive disjunction and abstract interpretation in order to approximate the behaviour of the while loop of that algorithm.

Systems XEXPYEQZ in **JaCoP**.

See also **common keyword:** GCD *(abstract interpretation)*.

Keywords **constraint arguments:** ternary constraint, pure functional dependency.

constraint type: arithmetic constraint, predefined constraint.

filtering: abstract interpretation.

modelling: functional dependency.

5.332 PRECEDENCE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Scheduling

Constraint PRECEDENCE(TASKS)

Argument TASKS : collection(origin−dvar, duration−dvar)

Restrictions
required(TASKS, [origin, duration])
TASKS.duration ≥ 0

Purpose All consecutive pairs of tasks of the collection TASKS should be ordered (i.e., the end of the first task of a pair should be less than or equal to the start of the second task of the same pair).

Example

$$\left(\left\langle\begin{array}{ll} \texttt{origin}-1 & \texttt{duration}-3, \\ \texttt{origin}-4 & \texttt{duration}-0, \\ \texttt{origin}-5 & \texttt{duration}-2, \\ \texttt{origin}-8 & \texttt{duration}-1 \end{array}\right\rangle\right)$$

Since the tasks are ordered (i.e., $1+3 \leq 4$, $4+0 \leq 5$, $5+2 \leq 8$) the PRECEDENCE constraint holds.

Typical
$|\texttt{TASKS}| > 2$
TASKS.duration ≥ 1

Symmetries

- TASKS.duration can be decreased to any value ≥ 0.
- One and the same constant can be added to the origin attribute of all items of TASKS.

Arg. properties Contractible wrt. TASKS.

See also
common keyword: INCREASING *(order constraint)*.
implies: DISJUNCTIVE.
implies (items to collection): LEX_CHAIN_LESSEQ.

Keywords
constraint type: decomposition, order constraint.
filtering: arc-consistency.

Arc input(s)	TASKS
Arc generator	$PATH \mapsto$ collection(tasks1, tasks2)
Arc arity	2
Arc constraint(s)	tasks1.origin + tasks1.duration $\leq$ tasks2.origin
Graph property(ies)	**NARC**$= \|$TASKS$\| - 1$

Graph model Since we are only interested by the constraints linking two consecutive items of the collection TASKS we use $PATH$ to generate the arcs of the initial graph.

Parts (A) and (B) of Figure 5.696 respectively show the initial and final graph of the first example of the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

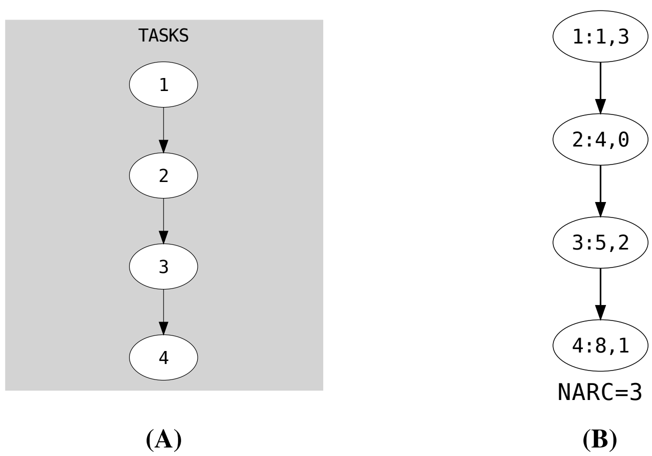


Figure 5.696: Initial and final graph of the PRECEDENCE constraint

5.333 PRODUCT_CTR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Arithmetic constraint.

Constraint PRODUCT_CTR(VARIABLES, CTR, VAR)

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint the product of a set of domain variables. More precisely, let P denote the product of the variables of the VARIABLES collection. Enforce the following constraint to hold: P CTR VAR.

Example $(\langle 2, 1, 4\rangle, =, 8)$

The PRODUCT_CTR constraint holds since its last argument VAR $= 8$ is equal (i.e., CTR is set to $=$) to $2 \cdot 1 \cdot 4$.

Typical

$|\text{VARIABLES}| > 1$
$|\text{VARIABLES}| < 10$
range(VARIABLES.var) > 1
VARIABLES.var $\neq 0$
CTR $\in [=, <, \geq, >, \leq]$
VAR $\neq 0$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Contractible wrt. VARIABLES when CTR $\in [<, \leq]$ and minval(VARIABLES.var) > 0.
- Aggregate: VARIABLES(union), CTR(id), VAR($*$) when CTR $\in [=]$.

Used in CUMULATIVE_PRODUCT.

See also **common keyword:** RANGE_CTR, SUM_CTR *(arithmetic constraint)*.

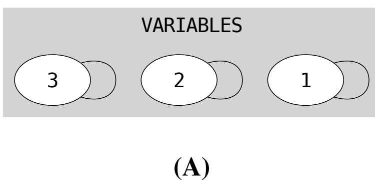
Keywords **characteristic of a constraint:** product.

constraint type: arithmetic constraint.

Arc input(s)	VARIABLES
Arc generator	*SELF* ↦ collection(variables)
Arc arity	1
Arc constraint(s)	TRUE
Graph property(ies)	**PROD**(VARIABLES, var) CTR VAR

Graph model Since we want to keep all the vertices of the initial graph we use the *SELF* arc generator together with the TRUE arc constraint. This predefined arc constraint always holds.

Parts (A) and (B) of Figure 5.697 respectively show the initial and final graph associated with the **Example** slot. Since we use the TRUE arc constraint both graphs are identical.



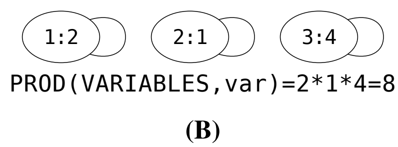


Figure 5.697: Initial and final graph of the PRODUCT_CTR constraint

5.334 PROPER_CIRCUIT

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Derived from CIRCUIT

Constraint PROPER_CIRCUIT(NODES)

Synonym CIRCUIT.

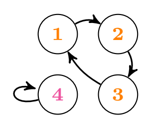
Argument NODES : collection(index−int, succ−dvar)

Restrictions
|NODES| > 1
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ ≤ |NODES|

Purpose Enforce to cover a digraph G described by the NODES collection with one circuit visiting once a subset of the vertices of G.

Example

$$\left(\left\langle\begin{array}{ll}\text{index}-1 & \text{succ}-2,\\ \text{index}-2 & \text{succ}-3,\\ \text{index}-3 & \text{succ}-1,\\ \text{index}-4 & \text{succ}-4\end{array}\right\rangle\right)$$



The PROPER_CIRCUIT constraint holds since its NODES argument depicts the following circuit visiting successively the vertices 1, 2, 3 and 1 (i.e., node 4 is not visited).

All solutions Figure 5.698 gives all solutions to the following non ground instance of the PROPER_CIRCUIT constraint: $S_1 \in [2,4]$, $S_2 \in [1,2]$, $S_3 \in [1,4]$, $S_4 \in [2,4]$, PROPER_CIRCUIT($\langle 1\ S_1, 2\ S_2, 3\ S_3, 4\ S_4\rangle$).

Typical |NODES| > 2

Symmetry Items of NODES are permutable.

Counting

Length (n)	2	3	4	5	6	7	8	9	10
Solutions	1	5	20	84	409	2365	16064	125664	1112073

Number of solutions for PROPER_CIRCUIT: domains $0..n$

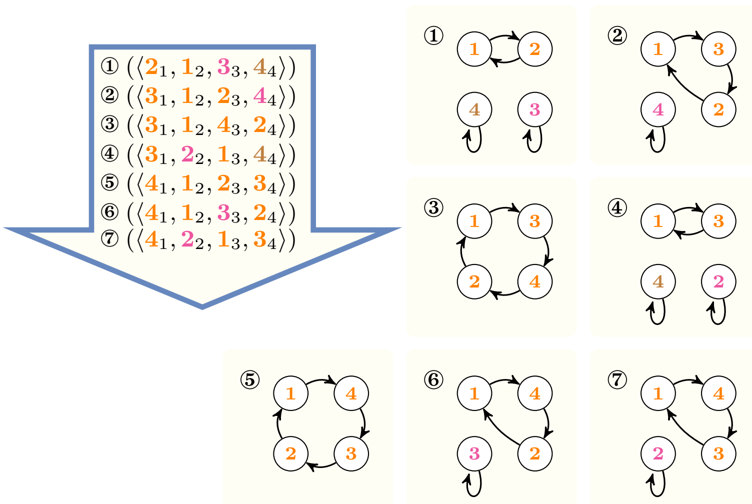


Figure 5.698: All solutions corresponding to the non ground example of the PROPER_CIRCUIT constraint of the **All solutions** slot; in the left-hand side the `index` attributes are displayed as indices of the `succ` attribute, while in the right-hand side they are directly displayed within each node.

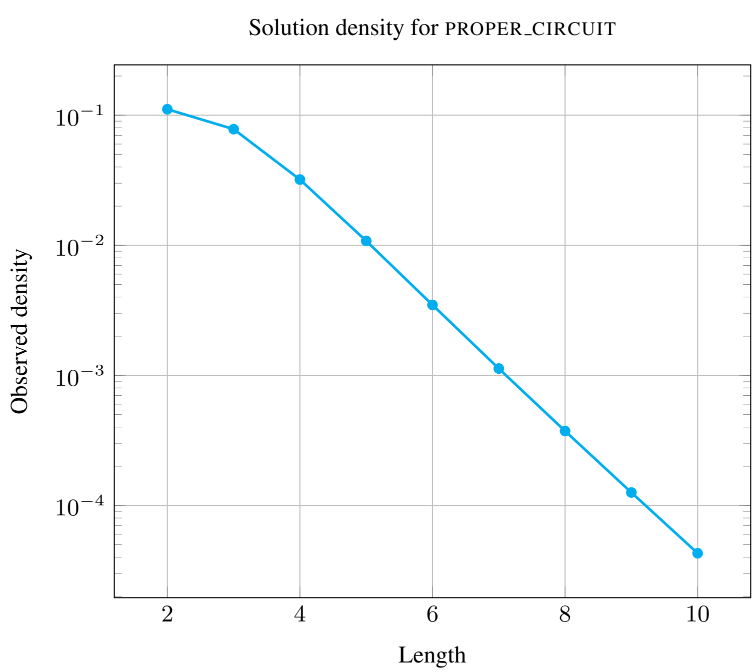

Solution density for PROPER_CIRCUIT

implied by: CIRCUIT.

implies: PERMUTATION, TWIN.

implies (items to collection): LEX_ALLDIFFERENT.

Keywords

combinatorial object: permutation.

constraint type: predefined constraint, graph constraint, graph partitioning constraint.

filtering: DFS-bottleneck.

final graph structure: circuit, one_succ.

5.335 PROPER_FOREST

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from TREE, [52].

Constraint PROPER_FOREST(NTREES, NODES)

Arguments

NTREES : dvar
NODES : collection(index−int, neighbour−svar)

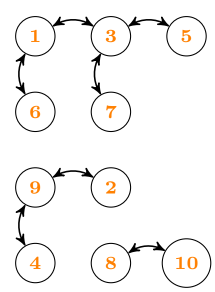
Restrictions

NTREES ≥ 0
required(NODES, [index, neighbour])
$|$NODES$|$ mod $2 = 0$
NODES.index ≥ 1
NODES.index $\leq |$NODES$|$
distinct(NODES, index)
NODES.neighbour ≥ 1
NODES.neighbour $\leq |$NODES$|$
NODES.neighbour $\neq$ NODES.index

Purpose Cover an undirected graph G by a set of NTREES trees (i.e., a *tree* is a connected graph without cycles that contains at least two vertices [114]) in such a way that each vertex of G belongs to one distinct tree.

Example

$$\left(3,\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{neighbour}-\{3,6\},\\ \texttt{index}-2 & \texttt{neighbour}-\{9\},\\ \texttt{index}-3 & \texttt{neighbour}-\{1,5,7\},\\ \texttt{index}-4 & \texttt{neighbour}-\{9\},\\ \texttt{index}-5 & \texttt{neighbour}-\{3\},\\ \texttt{index}-6 & \texttt{neighbour}-\{1\},\\ \texttt{index}-7 & \texttt{neighbour}-\{3\},\\ \texttt{index}-8 & \texttt{neighbour}-\{10\},\\ \texttt{index}-9 & \texttt{neighbour}-\{2,4\},\\ \texttt{index}-10 & \texttt{neighbour}-\{8\}\end{array}\right\rangle\right)$$



The PROPER_FOREST constraint holds since the undirected graph associated with the items of the NODES collection corresponds to a forest containing NTREES $= 3$ trees: each tree respectively involves the vertices $\{1,3,5,6,7\}$, $\{2,4,9\}$ and $\{8,10\}$.

Typical

NTREES > 0
$|$NODES$| > 1$

Symmetry Items of NODES are permutable.

Arg. properties Functional dependency: NTREES determined by NODES.

Remark Extension to the *minimum spanning tree* constraint is described in [152, 360, 363].

Algorithm A filtering algorithm for the PROPER_FOREST constraint was proposed by N. Beldiceanu *et al.* in [52]. It achieves hybrid-consistency and its running time is dominated by the complexity of finding all edges that do not belong to any maximum cardinality matching in an undirected n-vertex, m-edge graph, i.e., $O(m \cdot n)$. A second filtering algorithm with a worst-case time complexity of $O(m \cdot p)$, where p is the number of maximum extreme sets of the graph, based on Gallai-Edmonds decomposition [190, 159] was proposed by R. Cymer in [140].

Systems TREE in **Choco**.

See also **common keyword:** TREE *(connected component,tree)*.

Keywords **characteristic of a constraint:** undirected graph.

constraint arguments: constraint involving set variables.

constraint type: graph constraint.

filtering: hybrid-consistency.

final graph structure: connected component, tree, no cycle, symmetric.

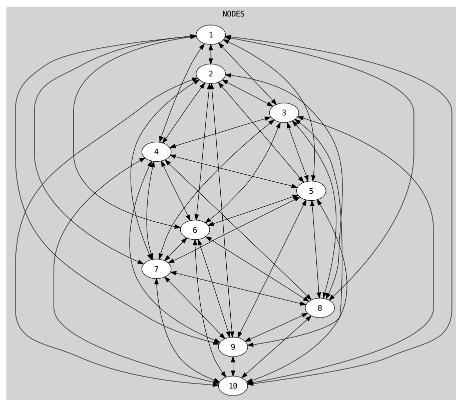
modelling: functional dependency.

Arc input(s)	NODES
Arc generator	$CLIQUE(\neq) \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	IN_SET(nodes2.index, nodes1.neighbour)
Graph property(ies)	• **NVERTEX**$= ($**NARC**$+2 *$ NTREES$)/2$ • **NCC**$=$ NTREES • **NVERTEX**$= \|$NODES$\|$
Graph class	SYMMETRIC

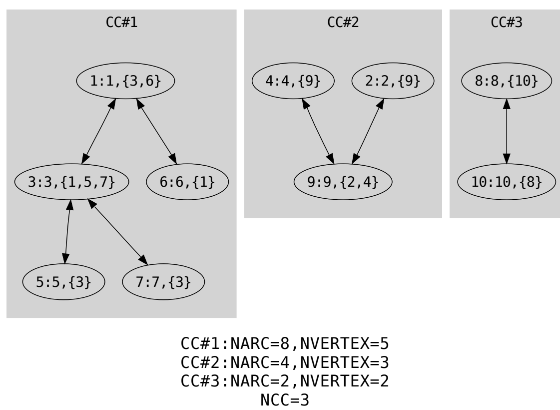
Graph model The graph constraint forces the following conditions:

- Each connected component of the final graph has n vertices and $2 \cdot (n-1)$ arcs. This is equivalent to the fact that each connected component has not any cycle.
- Since we use the $CLIQUE(\neq)$ arc-generator and since, by definition, the final graph does not contain any isolated vertex, each connected component of the final graph involves more than one vertex.
- The number of connected components of the final graph is equal to **NCC**.
- All the vertices of the initial graph belong to the final graph.
- The final graph is symmetric.

Parts (A) and (B) of Figure 5.699 respectively show the initial and final graph associated with the **Example** slot. For each connected component we display its number of arcs as well as its number of vertices. The PROPER_FOREST constraint holds since the final graph has NTREES $=$ **NCC** $= 3$ connected components and no cycle.



(A)



(B)

Figure 5.699: Initial and final graph of the PROPER_FOREST constraint

5.336 RANGE_CTR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Arithmetic constraint.

Constraint RANGE_CTR(VARIABLES, CTR, R)

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
R	:	dvar

Restrictions

$|\texttt{VARIABLES}| > 0$
required(VARIABLES, var)
$\texttt{CTR} \in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint the difference between the maximum value and the minimum value of a set of domain variables. More precisely, let RANGE denote the difference between the largest and the smallest variables of the VARIABLES collection plus one. Enforce the following constraint to hold: RANGE CTR R.

Example $(\langle 1, 9, 4\rangle, =, 9)$

The RANGE_CTR constraint holds since $\max(1, 9, 4) - \min(1, 9, 4) + 1$ is equal (i.e., CTR is set to $=$) to its last argument $\texttt{R} = 9$.

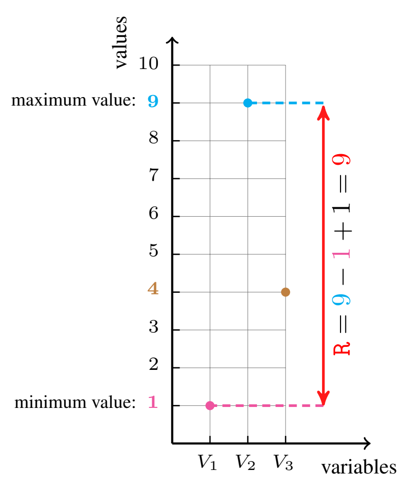


Figure 5.700: Illustration of the **Example** slot: three variables respectively fixed to values 1, 9 and 4, and their corresponding range $\texttt{R} = 9$

Typical

$|\texttt{VARIABLES}| > 1$
range$(\texttt{VARIABLES.var}) > 1$
$\texttt{CTR} \in [=, <, \geq, >, \leq]$

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

- Contractible wrt. VARIABLES when $\texttt{CTR} \in [<, \leq]$.
- Extensible wrt. VARIABLES when $\texttt{CTR} \in [\geq, >]$.

Used in SHIFT.

See also **common keyword:** PRODUCT_CTR, SUM_CTR *(arithmetic constraint)*.

Keywords **characteristic of a constraint:** range.

constraint type: arithmetic constraint.

Arc input(s)	VARIABLES
Arc generator	*SELF* $\mapsto$ collection(variables)
Arc arity	1
Arc constraint(s)	TRUE
Graph property(ies)	**RANGE**(VARIABLES, var) CTR R

Graph model Since we want to keep all the vertices of the initial graph we use the *SELF* arc generator together with the TRUE arc constraint. This predefined arc constraint always holds.

Parts (A) and (B) of Figure 5.701 respectively show the initial and final graph associated with the **Example** slot. Since we use the TRUE arc constraint both graphs are identical.

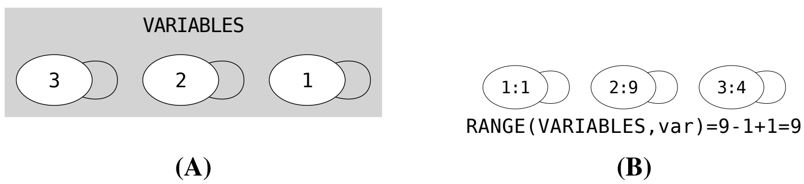

Figure 5.701: Initial and final graph of the RANGE_CTR constraint

5.337 RELAXED_SLIDING_SUM

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin CHIP

Constraint RELAXED_SLIDING_SUM(ATLEAST, ATMOST, LOW, UP, SEQ, VARIABLES)

Arguments

ATLEAST	:	int
ATMOST	:	int
LOW	:	int
UP	:	int
SEQ	:	int
VARIABLES	:	collection(var−dvar)

Restrictions

$\texttt{ATLEAST} \geq 0$
$\texttt{ATMOST} \geq \texttt{ATLEAST}$
$\texttt{ATMOST} \leq |\texttt{VARIABLES}| - \texttt{SEQ} + 1$
$\texttt{UP} \geq \texttt{LOW}$
$\texttt{SEQ} > 0$
$\texttt{SEQ} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose There are between ATLEAST and ATMOST sequences of SEQ consecutive variables of the collection VARIABLES such that the sum of the variables of the sequence is in [LOW, UP].

Example $(3, 4, 3, 7, 4, \langle 2, 4, 2, 0, 0, 3, 4\rangle)$

Within the sequence 2 4 2 0 0 3 4 we have exactly 3 subsequences of $\texttt{SEQ} = 4$ consecutive values such that their sums is located within the interval $[\texttt{LOW}, \texttt{UP}] = [3, 7]$: subsequences 4 2 0 0, 2 0 0 3 and 0 0 3 4. Consequently the RELAXED_SLIDING_SUM constraint holds since the number of such subsequences is located within the interval $[\texttt{ATLEAST}, \texttt{ATMOST}] = [3, 4]$.

Typical

$\texttt{SEQ} > 1$
$\texttt{SEQ} < |\texttt{VARIABLES}|$
$\text{range}(\texttt{VARIABLES.var}) > 1$
$\texttt{ATLEAST} > 0 \vee \texttt{ATMOST} < |\texttt{VARIABLES}| - \texttt{SEQ} + 1$

Symmetries

- ATLEAST can be decreased to any value ≥ 0.
- ATMOST can be increased to any value $\leq |\texttt{VARIABLES}| - \texttt{SEQ} + 1$.
- Items of VARIABLES can be reversed.

Algorithm [32].

See also

hard version: SLIDING_SUM.

used in graph description: SUM_CTR *(the sliding constraint)*.

Keywords

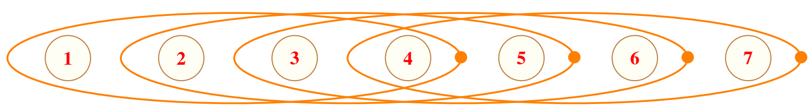
characteristic of a constraint: hypergraph.

combinatorial object: sequence.

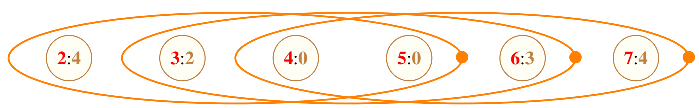
constraint type: sliding sequence constraint, soft constraint, relaxation.

Arc input(s)	VARIABLES
Arc generator	$PATH \mapsto$collection
Arc arity	SEQ
Arc constraint(s)	• SUM_CTR(collection, $\geq$, LOW) • SUM_CTR(collection, $\leq$, UP)
Graph property(ies)	• **NARC** $\geq$ ATLEAST • **NARC** $\leq$ ATMOST

Graph model Parts (A) and (B) of Figure 5.702 respectively show the initial and final graph associated with the **Example** slot. For each vertex of the graph we show its corresponding position within the collection of variables. The constraint associated with each arc corresponds to a conjunction of two sum_ctr constraints involving 4 consecutive variables. In Part (B), we did not put vertex 1 since the single arc constraint that mentions vertex 1 does not hold (i.e., the sum $2 + 4 + 2 + 0 = 8$ is not located in interval $[3, 7]$). However, the directed hypergraph contains 3 arcs, so the RELAXED_SLIDING_SUM constraint is satisfied since it was requested to have between 3 and 4 arcs.



(A)



(B)

Figure 5.702: (A) Initial and (B) final graph of the RELAXED_SLIDING_SUM$(3, 4, 3, 7, \mathbf{4}, \langle 2, \mathbf{4}, \mathbf{2}, \mathbf{0}, \mathbf{0}, \mathbf{3}, \mathbf{4}\rangle)$ constraint of the **Example** slot where each ellipse represents an hyperedge involving SEQ $=$ **4** vertices (e.g., the rightmost ellipse represents the constraint $0 + 0 + 3 + 4 \in [3, 7]$)

5.338 REMAINDER

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic.

Constraint REMAINDER(Q, D, R)

Synonyms MODULO, MOD.

Arguments

Q : dvar
D : dvar
R : dvar

Restrictions

$\mathtt{Q} \geq 0$
$\mathtt{D} > 0$
$\mathtt{R} \geq 0$
$\mathtt{R} < \mathtt{D}$

Purpose Enforce R to be equal to the remainder of the division of Q by D.

Example $(15, 2, 1)$

The REMAINDER constraint holds since 1 is the rest of the division of 15 by 2.

Arg. properties Functional dependency: R determined by Q and D.

Keywords

constraint arguments: ternary constraint, pure functional dependency.
constraint type: predefined constraint, arithmetic constraint.
modelling: functional dependency.

5.339 ROOTS

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [69]

Constraint ROOTS(S, T, VARIABLES)

Arguments

S	:	svar
T	:	svar
VARIABLES	:	collection(var−dvar)

Restrictions

$\texttt{S} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose

S is the set of indices of the variables in the collection VARIABLES taking their values in T; $\texttt{S} = \{i \mid \texttt{VARIABLES}[i].\texttt{var} \in \texttt{T}\}$. Positions are numbered from 1.

Example

$(\{2,4,5\}, \{2,3,8\}, \langle 1,3,1,2,3\rangle)$

The ROOTS constraint holds since values 2 and 3 in T occur in the collection $\langle 1,3,1,2,3\rangle$ only at positions $\texttt{S} = \{2,4,5\}$. The value $8 \in \texttt{T}$ does not occur within the collection $\langle 1,3,1,2,3\rangle$.

Typical

$|\texttt{VARIABLES}| > 1$
range(VARIABLES.var) > 1

Usage

Bessière et al. showed [69] that many counting and occurence constraints can be specified with two *global primitives*: ROOTS and RANGE. For example, the COUNT constraint can be decomposed into one ROOTS constraint: COUNT(VAL, VARS, OP, NVAR) iff ROOTS(S, {VAL}, VARS) $\wedge$ |S| OP NVAR.

ROOTS does not count but collects the set of variables using particular values. It provides then a way of channeling. ROOTS generalises, for example, the LINK_SET_TO_BOOLEANS constraint, LINK_SET_TO_BOOLEANS(S, BOOLEANS) iff ROOTS(S, {1}, BOOLEANS.bool), or may be used instead of the DOMAIN_CONSTRAINT.

Other examples of reformulations are given in [73].

Algorithm

In [72], Bessière *et al.* shows that enforcing hybrid-consistency on ROOTS is NP-hard. They consider the decomposition of ROOTS into a network of ternary constraints: $\forall i$, $i \in \texttt{S} \Rightarrow \texttt{VARIABLES}[i].\texttt{var} \in \texttt{T}$ and $\texttt{VARIABLES}[i].\texttt{var} \Rightarrow \texttt{T} \wedge i \in \texttt{S}$. Enforcing bound consistency on the decomposition achieves bound consistency on ROOTS. Enforcing hybrid consistency on the decomposition achieves at least bound consistency on ROOTS, until hybrid consistency in some special cases:

- $dom(\texttt{VARIABLES}[i].\texttt{var}) \subset \underline{\texttt{T}}$, $\forall i \in \underline{\texttt{S}}$,
- $dom(\texttt{VARIABLES}[i].\texttt{var}) \cap \overline{\texttt{T}} = \emptyset$, $\forall i \notin \overline{\texttt{S}}$,

- VARIABLES are ground,
- T is ground.

Enforcing hybrid consistency on the decomposition can be done in $O(nd)$ with $n = |\texttt{VARIABLES}|$ and d the maximum domain size of VARIABLES$[i]$.var and T.

Systems ROOTS in **Gecode**, ROOTS in **MiniZinc**.

Graph model

5.340 SAME

DESCRIPTION LINKS GRAPH AUTOMATON

Origin N. Beldiceanu

Constraint SAME(VARIABLES1, VARIABLES2)

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)

Restrictions

|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose The variables of the VARIABLES2 collection correspond to the variables of the VARIABLES1 collection according to a permutation.

Example $(\langle 1, 9, 1, 5, 2, 1\rangle, \langle 9, 1, 1, 1, 2, 5\rangle)$

The SAME constraint holds since values 1, 2, 5 and 9 have the same number of occurrences within both collections $\langle 1, 9, 1, 5, 2, 1\rangle$ and $\langle 9, 1, 1, 1, 2, 5\rangle$. Figure 5.704 illustrates this correspondence.

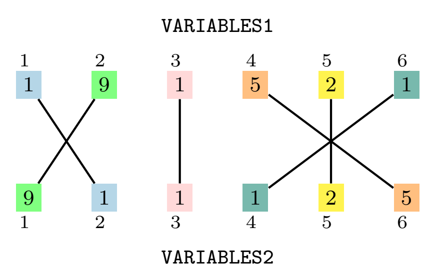

Figure 5.704: Illustration of the correspondence between the items of the VARIABLES1 and of the VARIABLES2 collections of the **Example** slot

All solutions Figure 5.705 gives all solutions to the following non ground instance of the SAME constraint: $U_1 \in [0, 2]$, $U_2 \in [1, 2]$, $U_3 \in [1, 2]$, $V_1 \in [0, 1]$, $V_2 \in [2, 4]$, $V_3 \in [2, 3]$, SAME($\langle U_1, U_2, U_3\rangle, \langle V_1, V_2, V_3\rangle$).

Typical

|VARIABLES1| > 1
range(VARIABLES1.var) > 1
range(VARIABLES2.var) > 1

① $(\langle 0, 2, 2\rangle, \langle 0, 2, 2\rangle)$
② $(\langle 1, 2, 2\rangle, \langle 1, 2, 2\rangle)$
③ $(\langle 2, 1, 2\rangle, \langle 1, 2, 2\rangle)$
④ $(\langle 2, 2, 1\rangle, \langle 1, 2, 2\rangle)$

Figure 5.705: All solutions corresponding to the non ground example of the SAME constraint of the **All solutions** slot where identical values are coloured in the same way in both collections

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Arg. properties

Aggregate: VARIABLES1(union), VARIABLES2(union).

Usage

The SAME constraint can be used in the following contexts:

- Pairing problems taken from [54]. The organisation Doctors Without Borders has a list of doctors and a list of nurses, each of whom volunteered to go on one mission in the next year. Each volunteer specifies a list of possible dates and each mission involves one doctor and one nurse. The task is to produce a list of pairs such that each pair includes a doctor and a nurse who are available at the same date and each volunteer appears in exactly one pair. The problem is modelled by a SAME$(D = d_1, d_2, \ldots, d_m, N = n_1, n_2, \ldots, n_m)$ constraint where each doctor is represented by a domain variable in D and each nurse by a domain variable in N. For a given doctor or nurse the corresponding domain variable gives the dates when the person is available. When the number of nurses is different from the number of doctors we replace the SAME constraint by a USED_BY constraint.
- Timetabling problems where we wish to produce fair schedules for different persons is a second use of the SAME constraint. Assume we need to generate a plan over a period of D consecutive days for P persons. For each day d and each person p we need to decide whether person p works in the morning shift, in the afternoon shift, in the night shift or does not work at all on day d. In a fair schedule, the number of morning shifts should be the same for all the persons. The same condition holds for the afternoon and the night shifts as well as for the days off. We create for each person p the sequence of variables $v_{p,1}, v_{p,2}, \ldots, v_{p,D}$. $v_{p,D}$ is equal to one of $0, 1, 2$ and 3, depending on whether person p does not work, works in the morning, in the afternoon or during the night on day d. We can use $P-1$ SAME constraints to express the fact that $v_{1,1}, v_{1,2}, \ldots, v_{1,D}$ should be a permutation of $v_{p,1}, v_{p,2}, \ldots, v_{p,D}$ for each $(1 < p \leq P)$.
- The SAME constraint can also be used as a channelling constraint for modelling the following recurring pattern: given the number of 1s in each line and each column of

a 0-1 matrix $\mathcal{M}$ with n rows and m columns, reconstruct the matrix. This pattern usually occurs with additional constraints about compatible positions of the 1s, or about the overall shape reconstructed from all the 1's (e.g., convexity, connectivity). If we restrict ourselves to the basic pattern there is an $O(mn)$ algorithm for reconstructing a $m \cdot n$ matrix from its horizontal and vertical directions [189]. We show how to model this pattern with the SAME constraint. Let l_i $(1 \leq i \leq n)$ and c_j $(1 \leq j \leq m)$ denote respectively, the required number of 1s in the i^{th} row and the j^{th} column of $\mathcal{M}$. We number the entries of the matrix as shown in the left-hand side of 5.706. For row i we create l_i domain variables v_{ik} where $k \in [1, l_i]$. Similarly, for each column j we create c_j domain variables u_{jk} where $k \in [1, c_i]$. The domain of each variable contains the set of entries that belong to the row or column that the variable corresponds to. Thus, each domain variable represents a 1 that appears in the designated row or column. Let $\mathcal{V}$ be the set of variables corresponding to rows and $\mathcal{U}$ be the set of variables corresponding to columns. To make sure that each 1 is placed in a different entry, we impose the constraint ALLDIFFERENT$(\mathcal{U})$. In addition, the constraint SAME$(\mathcal{U}, \mathcal{V})$ enforces that the 1s exactly coincide on the rows and the columns. A solution is shown on the right-hand side of 5.706. Note that the SAME_AND_GLOBAL_CARDINALITY constraint allows one to model the matrix reconstruction problem without the additional ALLDIFFERENT constraint.

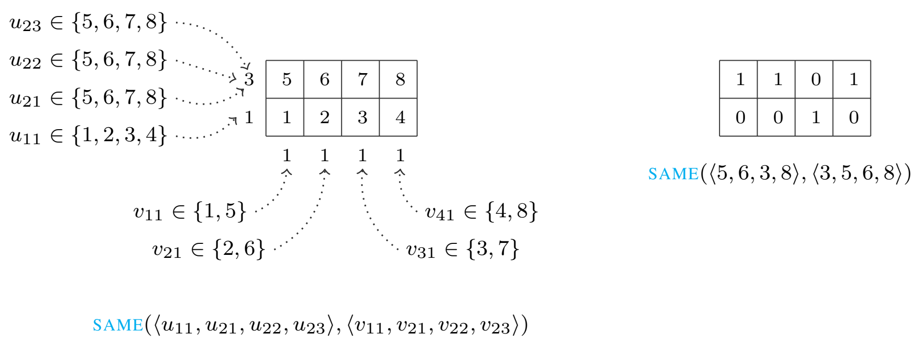

Figure 5.706: Modelling the 0-1 matrix reconstruction problem with the SAME constraint (variable u_{11} corresponds to the position of value 1 in the first row, variables u_{21}, u_{22}, u_{23} correspond to the position of value 1 in the second row, and variables v_{11}, v_{21}, v_{31}, v_{41} respectively to the positions of value 1 in the first, second, third and fourth columns)

Remark The SAME constraint is a relaxed version of the SORT constraint introduced in [308]. We do not enforce the second collection of variables to be sorted in increasing order.

If we interpret the collections `VARIABLES1` and `VARIABLES2` as two multisets variables [251], the SAME constraint can be considered as an equality constraint between two multisets variables.

The SAME constraint can be modelled by two GLOBAL_CARDINALITY constraints. For example, the SAME constraint

$$\text{SAME}\left(\begin{array}{l}\langle \texttt{var}-x_1, \texttt{var}-x_2\rangle,\\ \langle \texttt{var}-y_1, \texttt{var}-y_2\rangle,\end{array}\right)$$

where the union of the domains of the different variables is $\{1,2,3,4\}$ corresponds to the conjunction of the following two GLOBAL_CARDINALITY constraints:

$$\text{GLOBAL\_CARDINALITY}\left(\begin{array}{l}\langle\ \mathtt{var}-x_1,\mathtt{var}-x_2\ \rangle,\\ \left\langle\begin{array}{ll}\mathtt{val}-1 & \mathtt{noccurrence}-c_1,\\ \mathtt{val}-2 & \mathtt{noccurrence}-c_2,\\ \mathtt{val}-3 & \mathtt{noccurrence}-c_3,\\ \mathtt{val}-4 & \mathtt{noccurrence}-c_4\end{array}\right\rangle\end{array}\right)$$

$$\text{GLOBAL\_CARDINALITY}\left(\begin{array}{l}\langle\ \mathtt{var}-y_1,\mathtt{var}-y_2\ \rangle,\\ \left\langle\begin{array}{ll}\mathtt{val}-1 & \mathtt{noccurrence}-c_1,\\ \mathtt{val}-2 & \mathtt{noccurrence}-c_2,\\ \mathtt{val}-3 & \mathtt{noccurrence}-c_3,\\ \mathtt{val}-4 & \mathtt{noccurrence}-c_4\end{array}\right\rangle\end{array}\right)$$

As shown by the next example, the consistency for all variables of the two GLOBAL_CARDINALITY constraints does not implies consistency for the corresponding SAME constraint. This is the case, for example, when the domains of x_1, x_2, y_1 and y_2 is respectively equal to $\{1,2\}$, $\{3,4\}$, $\{1,2,3,4\}$ and $\{3,4\}$. The conjunction of the two GLOBAL_CARDINALITY constraints does not remove values 3 and 4 from y_1.

In his PhD thesis, W.-J. van Hoeve introduces a soft version of the SAME constraint where the cost is the minimum number of variables to assign differently in order to get back to a solution [434, page 78]. In the context of the SAME constraint this violation cost corresponds to the difference between the number of variables in VARIABLES1 and the number of values that both occur in VARIABLES1 and in VARIABLES2 (provided that one value of VARIABLES1 matches at most one value of VARIABLES2).

Algorithm In [53, 54, 55, 242], it is shown how to model this constraint by a flow network that enables to compute arc-consistency and bound-consistency. The rightmost part of Figure 3.31 illustrates this flow model. Unlike the networks used for ALLDIFFERENT and GLOBAL_CARDINALITY, the network now has three sets of nodes, so the algorithms are more complex, in particular the efficient bound-consistency algorithm.

More recently [138, 139] presents a second filtering algorithm also achieving arc-consistency based on a mapping of the solutions to the SAME constraint to perfect matchings in a bipartite intersection graph derived from the domain of the variables of the constraint in the following way. To each variable of the VARIABLES1 and VARIABLES2 collection corresponds a vertex of the intersection graph. There is an edge between a vertex associated with a variable of the VARIABLES1 collection and a vertex associated with a variable of the VARIABLES2 collection if and only if the corresponding variables have at least one value in common in their domains.

Reformulation The SAME(VARIABLES1, VARIABLES2) constraint can be reformulated as the conjunction SORT(VARIABLES1, SORTED_VARIABLES) $\wedge$ SORT(VARIABLES2, SORTED_VARIABLES).

Used in K_SAME.

See also **generalisation:** CORRESPONDENCE *(*PERMUTATION *parameter added)*, SAME_INTERVAL *(*variable *replaced by* variable/constant*)*, SAME_MODULO *(*variable *replaced by* variable mod constant*)*, SAME_PARTITION *(*variable *replaced by* variable $\in$ partition*)*.

implies: SAME_INTERSECTION, USED_BY.

related to a common problem: COLORED_MATRIX *(matrix reconstruction problem)*.

soft variant: SOFT_SAME_VAR *(variable-based violation measure)*.

system of constraints: K_SAME.

used in reformulation: SORT.

Keywords

characteristic of a constraint: sort based reformulation, automaton, automaton with array of counters.

combinatorial object: permutation, multiset.

constraint arguments: constraint between two collections of variables.

filtering: bipartite matching, flow, arc-consistency, bound-consistency, DFS-bottleneck.

modelling: channelling constraint, equality between multisets.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	• for all connected components: **NSOURCE**=**NSINK** • **NSOURCE**= |VARIABLES1| • **NSINK**= |VARIABLES2|

Graph model Parts (A) and (B) of Figure 5.707 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. The SAME constraint holds since:

- Each connected component of the final graph has the same number of sources and of sinks.
- The number of sources of the final graph is equal to |VARIABLES1|.
- The number of sinks of the final graph is equal to |VARIABLES2|.

Signature Since the initial graph contains only sources and sinks, and since isolated vertices are eliminated from the final graph, we make the following observations:

- Sources of the initial graph cannot become sinks of the final graph,
- Sinks of the initial graph cannot become sources of the final graph.

From the previous observations and since we use the $PRODUCT$ arc generator on the collections VARIABLES1 and VARIABLES2, we have that the maximum number of sources and sinks of the final graph is respectively equal to |VARIABLES1| and |VARIABLES2|. Therefore we can rewrite **NSOURCE** $=$ |VARIABLES1| to **NSOURCE** $\geq$ |VARIABLES1| and simplify $\underline{\mathbf{NSOURCE}}$ to $\overline{\mathbf{NSOURCE}}$. In a similar way, we can rewrite **NSINK** $=$ |VARIABLES2| to **NSINK** $\geq$ |VARIABLES2| and simplify $\underline{\mathbf{NSINK}}$ to $\overline{\mathbf{NSINK}}$.

Automaton To each item of the collection VARIABLES1 corresponds a signature variable S_i that is equal to 0. To each item of the collection VARIABLES2 corresponds a signature variable $S_{i+|\texttt{VARIABLES1}|}$ that is equal to 1.

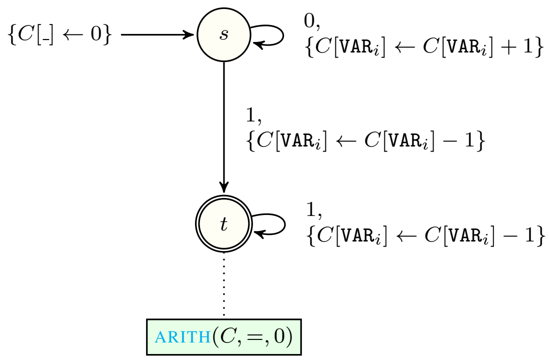

Figure 5.708: Automaton of the SAME constraint

5.341 SAME_AND_GLOBAL_CARDINALITY

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Conjoin SAME and GLOBAL_CARDINALITY

Constraint SAME_AND_GLOBAL_CARDINALITY(VARIABLES1, VARIABLES2, VALUES)

Synonyms SGCC, SAME_GCC, SAME_AND_GCC, SWC, SAME_WITH_CARDINALITIES.

Arguments

VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
VALUES	:	collection(val−int, noccurrence−dvar)

Restrictions

$|\mathtt{VARIABLES1}| = |\mathtt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
required(VALUES, [val, noccurrence])
distinct(VALUES, val)
$\mathtt{VALUES.noccurrence} \geq 0$
$\mathtt{VALUES.noccurrence} \leq |\mathtt{VARIABLES1}|$

Purpose

The variables of the VARIABLES2 collection correspond to the variables of the VARIABLES1 collection according to a permutation. In addition, each value VALUES$[i]$.val (with $i \in [1, |\mathtt{VALUES}|]$) should be taken by exactly VALUES$[i]$.noccurrence variables of the VARIABLES1 collection. Finally, each variable of VARIABLES1 should be assigned a value of VALUES$[i]$.val (with $i \in [1, |\mathtt{VALUES}|]$).

Example

$$\left(\begin{array}{l} \langle 1,9,1,5,2,1\rangle, \\ \langle 9,1,1,1,2,5\rangle, \\ \left\langle\begin{array}{ll} \mathtt{val}-1 & \mathtt{noccurrence}-3, \\ \mathtt{val}-2 & \mathtt{noccurrence}-1, \\ \mathtt{val}-5 & \mathtt{noccurrence}-1, \\ \mathtt{val}-7 & \mathtt{noccurrence}-0, \\ \mathtt{val}-9 & \mathtt{noccurrence}-1 \end{array}\right\rangle \end{array}\right)$$

The SAME_AND_GLOBAL_CARDINALITY constraint holds since:

- The values 1, 9, 1, 5, 2, 1 assigned to VARIABLES1 correspond to a permutation of the values 9, 1, 1, 1, 2, 5 assigned to VARIABLES2.
- The values 1, 2, 5, 7 and 6 are respectively used 3, 1, 1, 0 and 1 times.

Typical

$|\mathtt{VARIABLES1}| > 1$
range(VARIABLES1.var) > 1
range(VARIABLES2.var) > 1
$|\mathtt{VALUES}| > 1$
range(VALUES.noccurrence) > 1
$|\mathtt{VARIABLES1}| > |\mathtt{VALUES}|$

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2) (VALUES).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES1.var or VARIABLES2.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.
- All occurrences of two distinct values in VARIABLES1.var, VARIABLES2.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES1.var, VARIABLES2.var or VALUES.val can be renamed to any unused value.

Arg. properties

Contractible wrt. VALUES.

Usage

See the SAME_AND_GLOBAL_CARDINALITY_LOW_UP constraint.

Algorithm

The filtering algorithm presented in [56] can be reused for pruning the variables of the VARIABLES1 and the VARIABLES2 collection. This algorithm does not restrict the noccurrence variables of the VALUES collection.

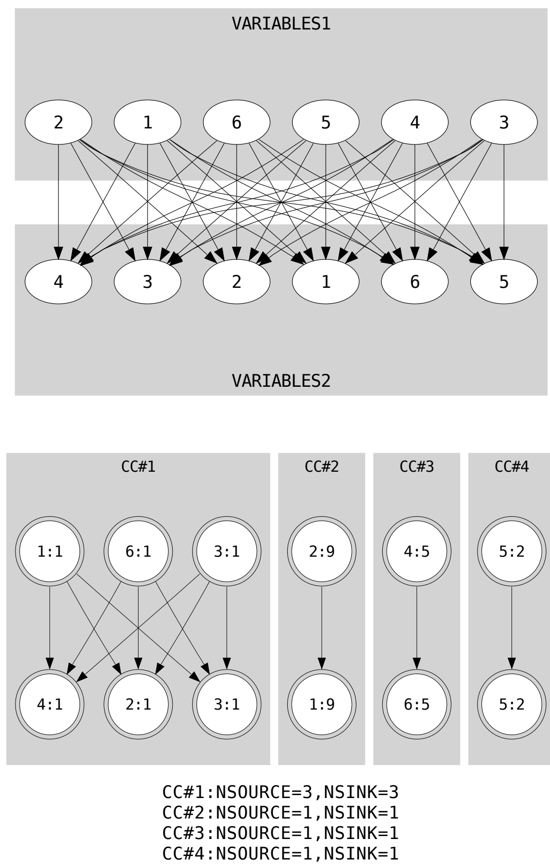
Graph model Parts (A) and (B) of Figure 5.709 respectively show the initial and final graph associated with the first graph constraint of the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint.



(A) **(B)**

Figure 5.709: Initial and final graph of the SAME_AND_GLOBAL_CARDINALITY constraint

5.342 SAME_AND_GLOBAL_CARDINALITY_LOW_UP

DESCRIPTION LINKS GRAPH

Origin

Derived from SAME and GLOBAL_CARDINALITY_LOW_UP

Constraint

SAME_AND_GLOBAL_CARDINALITY_LOW_UP(VARIABLES1, VARIABLES2, VALUES)

Arguments

VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
VALUES	:	collection(val−int, omin−int, omax−int)

Restrictions

|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)
required(VALUES, [val, omin, omax])
distinct(VALUES, val)
VALUES.omin ≥ 0
VALUES.omax ≤ |VARIABLES1|
VALUES.omin ≤ VALUES.omax

Purpose

The variables of the VARIABLES2 collection correspond to the variables of the VARIABLES1 collection according to a permutation. In addition, each value VALUES[i].val (with $i \in [1, |\text{VALUES}|]$) should be taken by at least VALUES[i].omin and at most VALUES[i].omax variables of the VARIABLES1 collection. Finally, each variable of VARIABLES1 should be assigned a value of VALUES[i].val (with $i \in [1, |\text{VALUES}|]$).

Example

$$\left(\begin{array}{l}\langle 1,9,1,5,2,1\rangle,\\ \langle 9,1,1,1,2,5\rangle,\\ \left\langle\begin{array}{lll}\text{val}-1 & \text{omin}-2 & \text{omax}-3,\\ \text{val}-2 & \text{omin}-1 & \text{omax}-1,\\ \text{val}-5 & \text{omin}-1 & \text{omax}-1,\\ \text{val}-7 & \text{omin}-0 & \text{omax}-2,\\ \text{val}-9 & \text{omin}-1 & \text{omax}-1\end{array}\right\rangle\end{array}\right)$$

The SAME_AND_GLOBAL_CARDINALITY_LOW_UP constraint holds since:

- The values 1, 9, 1, 5, 2, 1 assigned to |VARIABLES1| correspond to a permutation of the values 9, 1, 1, 1, 2, 5 assigned to |VARIABLES2|.
- The values 1, 2, 5, 7 and 6 are respectively used 3 ($2 \le 3 \le 3$), 1 ($1 \le 1 \le 1$), 1 ($1 \le 1 \le 1$), 0 ($0 \le 0 \le 2$) and 1 ($1 \le 1 \le 1$) times.

Typical

$|\texttt{VARIABLES1}| > 1$
$\texttt{range}(\texttt{VARIABLES1.var}) > 1$
$\texttt{range}(\texttt{VARIABLES2.var}) > 1$
$|\texttt{VALUES}| > 1$
$\texttt{VALUES.omin} \leq |\texttt{VARIABLES1}|$
$\texttt{VALUES.omax} > 0$
$\texttt{VALUES.omax} < |\texttt{VARIABLES1}|$
$|\texttt{VARIABLES1}| > |\texttt{VALUES}|$

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2) (VALUES).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value of VARIABLES1.var or VARIABLES2.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.
- Items of VALUES are permutable.
- VALUES.omin can be decreased to any value ≥ 0.
- VALUES.omax can be increased to any value $\leq |\texttt{VARIABLES1}|$.
- All occurrences of two distinct values in VARIABLES1.var, VARIABLES2.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES1.var, VARIABLES2.var or VALUES.val can be renamed to any unused value.

Arg. properties

Contractible wrt. VALUES.

Usage

The SAME_AND_GLOBAL_CARDINALITY_LOW_UP constraint can be used for modelling the following assignment problem with a single constraint. The organisation Doctors Without Borders has a list of doctors and a list of nurses, each of whom volunteered to go on one rescue mission. Each volunteer specifies a list of possible dates and each mission should include one doctor and one nurse. In addition we have for each date the minimum and maximum number of missions that should be effectively done. The task is to produce a list of pairs such that each pair includes a doctor and a nurse who are available on the same date and each volunteer appears in exactly one pair so that for each day we build the required number of missions.

Algorithm

In [56], the flow network that was used to model the SAME constraint [53, 54] is extended to support the cardinalities. Figure 3.32 illustrates this flow model. Then, algorithms are developed to compute arc-consistency and bound-consistency.

5.343 SAME_INTERSECTION

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from SAME and COMMON.

Constraint SAME_INTERSECTION(VARIABLES1, VARIABLES2)

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)

Restrictions

required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose Each value, which occurs both in the VARIABLES1 and in the VARIABLES2 collections, has the same number of occurrences in VARIABLES1 as well as in VARIABLES2.

Example $(\langle 1,9,1,5,2,1\rangle, \langle 9,1,1,1,3,5,8\rangle)$

First note that the values, which occur both in VARIABLES1 $= \langle 1,9,1,5,2,1\rangle$ as well as in VARIABLES2 $= \langle 9,1,1,1,3,5,8\rangle$ correspond to values 1, 5, and 9. Consequently, the SAME_INTERSECTION constraint holds since these values 1, 5, and 9 have the same number of occurrences in both collections (i.e., they respectively occur 3, 1, and 1 times within VARIABLES1 and VARIABLES2).

Typical

$|\texttt{VARIABLES1}| > 1$
range(VARIABLES1.var) > 1
$|\texttt{VARIABLES2}| > 1$
range(VARIABLES2.var) > 1

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

See also **common keyword:** COMMON, NVALUE_ON_INTERSECTION *(constraint on the intersection)*.

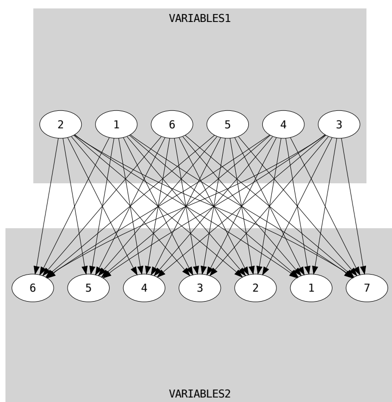
implied by: ALLDIFFERENT_ON_INTERSECTION, SAME.

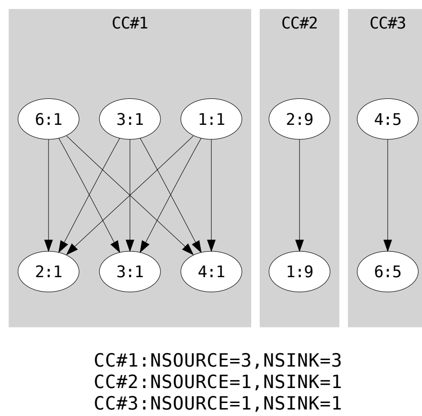
Keywords **constraint arguments:** constraint between two collections of variables.

constraint type: constraint on the intersection.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	for all connected components: **NSOURCE=NSINK**

Graph model Parts (A) and (B) of Figure 5.711 respectively show the initial and final graph associated with the **Example** slot. The SAME_INTERSECTION constraint holds since each connected component of the final graph has the same number of sources and sinks. Note that all the vertices corresponding to the variables that take values 2, 3 or 8 were removed from the final graph since there is no arc for which the associated equality constraint holds.





(A) **(B)**

Figure 5.711: Initial and final graph of the SAME_INTERSECTION constraint

5.344 SAME_INTERVAL

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from SAME.

Constraint SAME_INTERVAL(VARIABLES1, VARIABLES2, SIZE_INTERVAL)

Arguments

VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
SIZE_INTERVAL	:	int

Restrictions

|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)
SIZE_INTERVAL > 0

Purpose Let N_i (respectively M_i) denote the number of variables of the collection VARIABLES1 (respectively VARIABLES2) that take a value in the interval [SIZE_INTERVAL $\cdot$ i, SIZE_INTERVAL $\cdot$ i + SIZE_INTERVAL − 1. For all integer i we have $N_i = M_i$.

Example $(\langle 1, 7, 6, 0, 1, 7\rangle, \langle 8, 8, 8, 0, 1, 2\rangle, 3)$

In the example, the third argument SIZE_INTERVAL = 3 defines the following family of intervals $[3 \cdot k, 3 \cdot k + 2]$, where k is an integer. Consequently the values of the collection $\langle 1, 7, 6, 0, 1, 7\rangle$ are respectively located within intervals $[0, 2]$, $[6, 8]$, $[6, 8]$, $[0, 2]$, $[0, 2]$, $[6, 8]$. Therefore intervals $[0, 2]$ and $[6, 8]$ are respectively used 3 and 3 times. Similarly, the values of the collection $\langle 8, 8, 8, 0, 1, 2\rangle$ are respectively located within intervals $[6, 8]$, $[6, 8]$, $[6, 8]$, $[0, 2]$, $[0, 2]$, $[0, 2]$. As before intervals $[0, 2]$ and $[6, 8]$ are respectively used 3 and 3 times. Consequently the SAME_INTERVAL constraint holds. Figure 5.712 illustrates this correspondence.

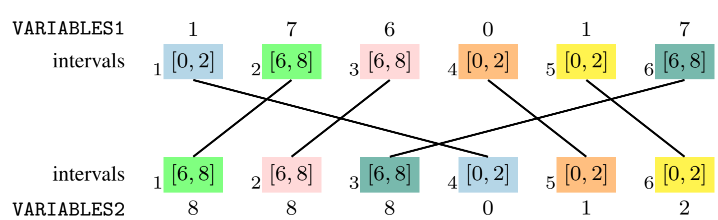


Figure 5.712: Illustration of the correspondence between the items of the VARIABLES1 and of the VARIABLES2 collections of the **Example** slot

Typical

$|\texttt{VARIABLES1}| > 1$
$\texttt{range}(\texttt{VARIABLES1.var}) > 1$
$\texttt{range}(\texttt{VARIABLES2.var}) > 1$
$\texttt{SIZE\_INTERVAL} > 1$
$\texttt{SIZE\_INTERVAL} < \texttt{range}(\texttt{VARIABLES1.var})$
$\texttt{SIZE\_INTERVAL} < \texttt{range}(\texttt{VARIABLES2.var})$

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2) (SIZE_INTERVAL).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value of VARIABLES.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Arg. properties

Aggregate: VARIABLES1(union), VARIABLES2(union), SIZE_INTERVAL(id).

Algorithm

See algorithm of the SAME constraint.

Used in

K_SAME_INTERVAL.

See also

implies: USED_BY_INTERVAL.

soft variant: SOFT_SAME_INTERVAL_VAR *(variable-based violation measure)*.

specialisation: SAME *(*variable/constant *replaced by* variable*)*.

system of constraints: K_SAME_INTERVAL.

Keywords

characteristic of a constraint: sort based reformulation.

combinatorial object: permutation.

constraint arguments: constraint between two collections of variables.

modelling: interval.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var/SIZE_INTERVAL = variables2.var/SIZE_INTERVAL
Graph property(ies)	• for all connected components: **NSOURCE**=**NSINK** • **NSOURCE**= |VARIABLES1| • **NSINK**= |VARIABLES2|

Graph model Parts (A) and (B) of Figure 5.713 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. The SAME_INTERVAL constraint holds since:

- Each connected component of the final graph has the same number of sources and of sinks.
- The number of sources of the final graph is equal to |VARIABLES1|.
- The number of sinks of the final graph is equal to |VARIABLES2|.

Signature Since the initial graph contains only sources and sinks, and since isolated vertices are eliminated from the final graph, we make the following observations:

- Sources of the initial graph cannot become sinks of the final graph,
- Sinks of the initial graph cannot become sources of the final graph.

From the previous observations and since we use the $PRODUCT$ arc generator on the collections VARIABLES1 and VARIABLES2, we have that the maximum number of sources and sinks of the final graph is respectively equal to |VARIABLES1| and |VARIABLES2|. Therefore we can rewrite **NSOURCE** = |VARIABLES1| to **NSOURCE** $\geq$ |VARIABLES1| and simplify $\underline{\overline{\textbf{NSOURCE}}}$ to $\overline{\textbf{NSOURCE}}$. In a similar way, we can rewrite **NSINK** = |VARIABLES2| to **NSINK** $\geq$ |VARIABLES2| and simplify $\underline{\overline{\textbf{NSINK}}}$ to $\overline{\textbf{NSINK}}$.

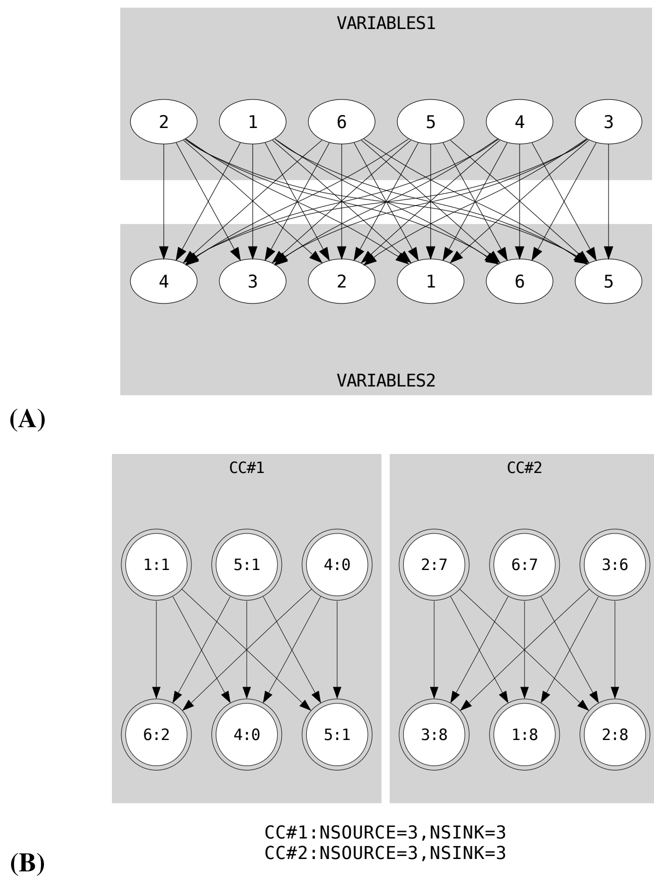

Figure 5.713: Initial and final graph of the SAME_INTERVAL constraint

5.345 SAME_MODULO

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin

Derived from SAME.

Constraint

SAME_MODULO(VARIABLES1, VARIABLES2, M)

Arguments

VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
M	:	int

Restrictions

|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)
M > 0

Purpose

For each integer R in $[0, \mathtt{M}-1]$, let $N1_R$ (respectively $N2_R$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that have R as a rest when divided by M. For all R in $[0, \mathtt{M}-1]$ we have that $N1_R = N2_R$.

Example

$(\langle 1, 9, 1, 5, 2, 1\rangle, \langle 6, 4, 1, 1, 5, 5\rangle, 3)$

The values of the first collection $\langle 1, 9, 1, 5, 2, 1\rangle$ are respectively associated with the equivalence classes $1 \bmod 3 = 1$, $9 \bmod 3 = 0$, $1 \bmod 3 = 1$, $5 \bmod 3 = 2$, $2 \bmod 3 = 2$, $1 \bmod 3 = 1$. Therefore the equivalence classes 0, 1, and 2 are respectively used 1, 3, and 2 times. Similarly, the values of the second collection $\langle 6, 4, 1, 1, 5, 5\rangle$ are respectively associated with the equivalence classes $6 \bmod 3 = 0$, $4 \bmod 3 = 1$, $1 \bmod 3 = 1$, $1 \bmod 3 = 1$, $5 \bmod 3 = 2$, $5 \bmod 3 = 2$. Therefore the equivalence classes 0, 1, and 2 are respectively used 1, 3, and 2 times. Consequently the SAME_MODULO constraint holds. Figure 5.714 illustrates this correspondence.

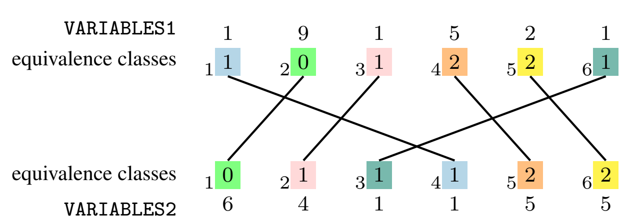

Figure 5.714: Illustration of the correspondence between the items of the VARIABLES1 and of the VARIABLES2 collections of the **Example** slot

Typical

$|\texttt{VARIABLES1}| > 1$
$\texttt{range}(\texttt{VARIABLES1.var}) > 1$
$\texttt{range}(\texttt{VARIABLES2.var}) > 1$
$\texttt{M} > 1$
$\texttt{M} < \texttt{maxval}(\texttt{VARIABLES1.var})$
$\texttt{M} < \texttt{maxval}(\texttt{VARIABLES2.var})$

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2) (M).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value u of VARIABLES.var can be replaced by any other value v such that v is congruent to u modulo M.

Arg. properties

Aggregate: VARIABLES1(union), VARIABLES2(union), M(id).

Used in

K_SAME_MODULO.

See also

implies: USED_BY_MODULO.

soft variant: SOFT_SAME_MODULO_VAR *(variable-based violation measure)*.

specialisation: SAME *(*variable mod constant *replaced by* variable*)*.

system of constraints: K_SAME_MODULO.

Keywords

characteristic of a constraint: sort based reformulation, modulo.

combinatorial object: permutation.

constraint arguments: constraint between two collections of variables.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var mod M = variables2.var mod M
Graph property(ies)	• for all connected components: **NSOURCE**=**NSINK** • **NSOURCE**= |VARIABLES1| • **NSINK**= |VARIABLES2|

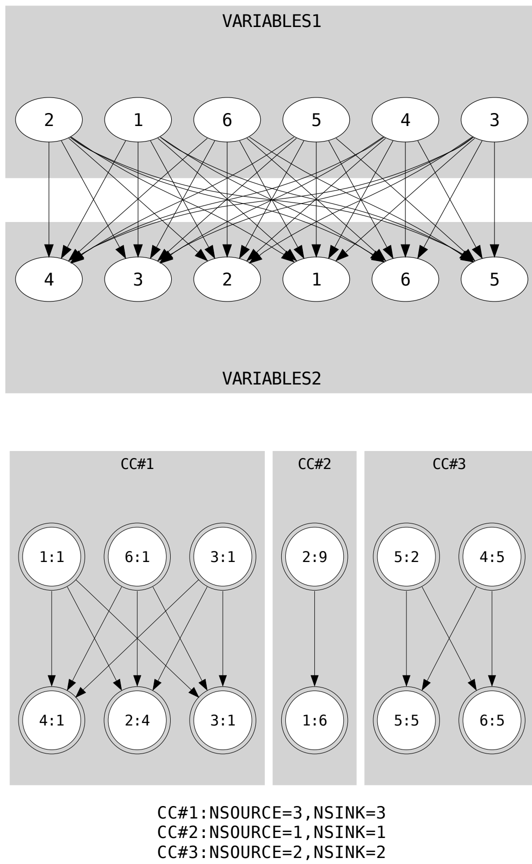
Graph model Parts (A) and (B) of Figure 5.715 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. The SAME_MODULO constraint holds since:

- Each connected component of the final graph has the same number of sources and of sinks.
- The number of sources of the final graph is equal to |VARIABLES1|.
- The number of sinks of the final graph is equal to |VARIABLES2|.

Signature Since the initial graph contains only sources and sinks, and since isolated vertices are eliminated from the final graph, we make the following observations:

- Sources of the initial graph cannot become sinks of the final graph,
- Sinks of the initial graph cannot become sources of the final graph.

From the previous observations and since we use the $PRODUCT$ arc generator on the collections VARIABLES1 and VARIABLES2, we have that the maximum number of sources and sinks of the final graph is respectively equal to |VARIABLES1| and |VARIABLES2|. Therefore we can rewrite $\mathbf{NSOURCE} = |\texttt{VARIABLES1}|$ to $\mathbf{NSOURCE} \geq |\texttt{VARIABLES1}|$ and simplify $\underline{\mathbf{NSOURCE}}$ to $\overline{\mathbf{NSOURCE}}$. In a similar way, we can rewrite $\mathbf{NSINK} = |\texttt{VARIABLES2}|$ to $\mathbf{NSINK} \geq |\texttt{VARIABLES2}|$ and simplify $\underline{\mathbf{NSINK}}$ to $\overline{\mathbf{NSINK}}$.



(A)

(B)

Figure 5.715: Initial and final graph of the SAME_MODULO constraint

5.346 SAME_PARTITION

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from SAME.

Constraint SAME_PARTITION(VARIABLES1, VARIABLES2, PARTITIONS)

Type VALUES : collection(val−int)

Arguments
VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)
PARTITIONS : collection(p − VALUES)

Restrictions
|VALUES| ≥ 1
required(VALUES, val)
distinct(VALUES, val)
|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)
required(PARTITIONS, p)
|PARTITIONS| ≥ 2

Purpose For each integer i in [1, |PARTITIONS|], let $N1_i$ (respectively $N2_i$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that take their values in the i^{th} partition of the collection PARTITIONS. For all i in [1, |PARTITIONS|] we have $N1_i = N2_i$.

Example
$$\left(\begin{array}{l}\langle 1,2,6,3,1,2\rangle, \\ \langle 6,6,2,3,1,3\rangle, \\ \langle \mathtt{p}-\langle 1,3\rangle, \mathtt{p}-\langle 4\rangle, \mathtt{p}-\langle 2,6\rangle\rangle\end{array}\right)$$

The different values of the collection $\langle 1,2,6,3,1,2\rangle$ are respectively associated with the partitions p − $\langle 1,3\rangle$, p − $\langle 2,6\rangle$, p − $\langle 2,6\rangle$, p − $\langle 1,3\rangle$, p − $\langle 1,3\rangle$, and p − $\langle 2,6\rangle$. Therefore partitions p − $\langle 1,3\rangle$ and p − $\langle 2,6\rangle$ are respectively used 3 and 3 times. Similarly, the different values of the collection $\langle 6,6,2,3,1,3\rangle$ are respectively associated with the partitions p − $\langle 2,6\rangle$, p − $\langle 2,6\rangle$, p − $\langle 2,6\rangle$, p − $\langle 1,3\rangle$, p − $\langle 1,3\rangle$, and p − $\langle 1,3\rangle$. As before partitions p − $\langle 1,3\rangle$ and p − $\langle 2,6\rangle$ are respectively used 3 and 3 times. Consequently the SAME_PARTITION constraint holds. Figure 5.716 illustrates this correspondence.

Typical
|VARIABLES1| > 1
range(VARIABLES1.var) > 1
range(VARIABLES2.var) > 1
|VARIABLES1| > |PARTITIONS|
|VARIABLES2| > |PARTITIONS|

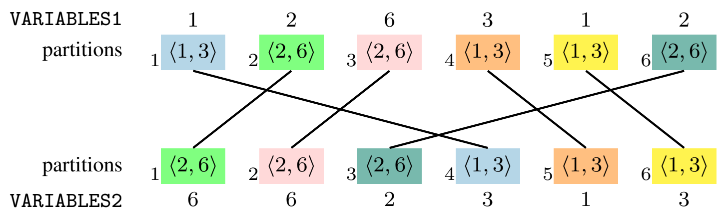


Figure 5.716: Illustration of the correspondence between the items of the VARIABLES1 and of the VARIABLES2 collections of the **Example** slot

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2) (PARTITIONS).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of VARIABLES.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Arg. properties

Aggregate: VARIABLES1(union), VARIABLES2(union), PARTITIONS(id).

Used in

K_SAME_PARTITION.

See also

implies: USED_BY_PARTITION.

soft variant: SOFT_SAME_PARTITION_VAR (*variable-based violation measure*).

specialisation: SAME (variable $\in$ partition *replaced by* variable).

system of constraints: K_SAME_PARTITION.

used in graph description: IN_SAME_PARTITION.

Keywords

characteristic of a constraint: sort based reformulation, partition.

combinatorial object: permutation.

constraint arguments: constraint between two collections of variables.

Arc input(s)	`VARIABLES1` `VARIABLES2`
Arc generator	$PRODUCT$ $\mapsto$ `collection`(`variables1`, `variables2`)
Arc arity	2
Arc constraint(s)	IN_SAME_PARTITION(`variables1.var`, `variables2.var`, `PARTITIONS`)
Graph property(ies)	• for all connected components: **NSOURCE**=**NSINK** • **NSOURCE**= |`VARIABLES1`| • **NSINK**= |`VARIABLES2`|

Graph model

Parts (A) and (B) of Figure 5.717 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. The SAME_PARTITION constraint holds since:

- Each connected component of the final graph has the same number of sources and of sinks.
- The number of sources of the final graph is equal to |`VARIABLES1`|.
- The number of sinks of the final graph is equal to |`VARIABLES2`|.

Signature

Since the initial graph contains only sources and sinks, and since isolated vertices are eliminated from the final graph, we make the following observations:

- Sources of the initial graph cannot become sinks of the final graph,
- Sinks of the initial graph cannot become sources of the final graph.

From the previous observations and since we use the $PRODUCT$ arc generator on the collections `VARIABLES1` and `VARIABLES2`, we have that the maximum number of sources and sinks of the final graph is respectively equal to |`VARIABLES1`| and |`VARIABLES2`|. Therefore we can rewrite $\mathbf{NSOURCE} = |\texttt{VARIABLES1}|$ to $\mathbf{NSOURCE} \geq |\texttt{VARIABLES1}|$ and simplify $\underline{\mathbf{NSOURCE}}$ to $\overline{\mathbf{NSOURCE}}$. In a similar way, we can rewrite $\mathbf{NSINK} = |\texttt{VARIABLES2}|$ to $\mathbf{NSINK} \geq |\texttt{VARIABLES2}|$ and simplify $\underline{\mathbf{NSINK}}$ to $\overline{\mathbf{NSINK}}$.

5.347 SAME_REMAINDER

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin learning

Constraint SAME_REMAINDER(VARIABLES, Q, R)

Arguments

VARIABLES	:	collection(var−dvar)
Q	:	dvar
R	:	dvar

Restrictions

|VARIABLES| > 0
required(VARIABLES, [var])
VARIABLES.var ≥ 0
Q > 1
Q $\leq$maxval(VARIABLES.var)
R ≥ 0
R $<$ Q

Purpose All variables of the VARIABLES collection have the same remainder R when divided by Q.

Example

$(\langle 4, 6, 4, 8\rangle, 2, 0)$
$(\langle 4, 1, 4, 7\rangle, 3, 1)$

The first SAME_REMAINDER constraint holds since all variables are even, i.e. Q $= 2$ and R $= 0$. The second SAME_REMAINDER constraint holds since, when divided by Q $= 3$ all variables have a remainder R equal to 1.

Typical

|VARIABLES| > 2
Q < 10

Symmetry Items of VARIABLES are permutable.

Keywords **constraint type:** arithmetic constraint.

5.348 SAME_SIGN

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint SAME_SIGN(VAR1, VAR2)

Arguments

VAR1	:	dvar
VAR2	:	dvar

Restriction

Purpose Enforce the fact that the product of the first and second variables is greater than or equal to 0.

Example $(7, 1)$

The SAME_SIGN constraint holds since 7 and 1 have the same sign.

Typical

VAR1 $\neq 0$
VAR2 $\neq 0$

Symmetry Arguments are permutable w.r.t. permutation (VAR1, VAR2).

See also **comparison swapped:** OPPOSITE_SIGN.

implied by: DIVISIBLE_OR, EQ, SIGN_OF.

Keywords **constraint arguments:** binary constraint.

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

5.349 SCALAR_PRODUCT

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic constraint.

Constraint SCALAR_PRODUCT(LINEARTERM, CTR, VAL)

Synonyms EQUATION, LINEAR, SUM_WEIGHT, WEIGHTEDSUM.

Arguments

LINEARTERM : collection(coeff−int, var−dvar)
CTR : atom
VAL : dvar

Restrictions

required(LINEARTERM, [coeff, var])
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint a linear term defined as the sum of products of coefficients and variables. More precisely, let S denote the sum of the product between a coefficient and its variable of the different items of the LINEARTERM collection. Enforce the following constraint to hold: S CTR VAL.

Example $(\langle \texttt{coeff}-1\ \texttt{var}-1, \texttt{coeff}-3\ \texttt{var}-1, \texttt{coeff}-1\ \texttt{var}-4\rangle, =, 8)$

The SCALAR_PRODUCT constraint holds since the condition $1\cdot 1+3\cdot 1+1\cdot 4=8$ is satisfied.

Typical

$|\texttt{LINEARTERM}| > 1$
range(LINEARTERM.coeff) > 1
range(LINEARTERM.var) > 1
CTR $\in [=, <, \geq, >, \leq]$

Symmetries

- Items of LINEARTERM are permutable.
- Attributes of LINEARTERM are permutable w.r.t. permutation (coeff, var) (*permutation not necessarily applied to all items*).

Arg. properties

- Contractible wrt. LINEARTERM when CTR $\in [<, \leq]$, minval(LINEARTERM.coeff) ≥ 0 and minval(LINEARTERM.var) ≥ 0.
- Extensible wrt. LINEARTERM when CTR $\in [\geq, >]$, minval(LINEARTERM.coeff) ≥ 0 and minval(LINEARTERM.var) ≥ 0.
- Aggregate: LINEARTERM(union), CTR(id), VAL(+).

Remark The SCALAR_PRODUCT constraint is called LINEAR in **Gecode** (http://www.gecode.org/). It is called SUM_WEIGHT in **JaCoP** (http://www.jacop.eu/). In the 2008 CSP solver competition the SCALAR_PRODUCT constraint was called WEIGHTEDSUM and required VAL to be fixed.

Algorithm Most filtering algorithms first merge multiple occurrences of identical variables in order to potentially make more deductions. When CTR corresponds to the *less than or equal to* constraint, a filtering algorithm achieving bound-consistency for the SCALAR_PRODUCT constraint with large numbers of variables is described in [214].

Systems EQUATION in **Choco**, LINEAR in **Gecode**, SUMWEIGHT in **JaCoP**, SCALAR_PRODUCT in **SICStus**.

See also **specialisation:** SUM_CTR *(arithmetic constraint where all coefficients are equal to* 1*)*.

Keywords **characteristic of a constraint:** sum.

constraint type: predefined constraint, arithmetic constraint.

filtering: duplicated variables.

5.350 SEQUENCE_FOLDING

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin J. Pearson

Constraint SEQUENCE_FOLDING(LETTERS)

Argument LETTERS : collection(index−int, next−dvar)

Restrictions
|LETTERS| ≥ 1
required(LETTERS, [index, next])
LETTERS.index ≥ 1
LETTERS.index ≤ |LETTERS|
increasing_seq(LETTERS, index)
LETTERS.next ≥ 1
LETTERS.next ≤ |LETTERS|

Purpose Express the fact that a sequence is folded in a way that no crossing occurs. A sequence is modelled by a collection of letters. For each letter l_1 of a sequence, we indicate the next letter l_2 located after l_1 that is directly in contact with l_1 (l_1 itself if such a letter does not exist).

Example

$$\left(\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{next}-1,\\ \texttt{index}-2 & \texttt{next}-8,\\ \texttt{index}-3 & \texttt{next}-3,\\ \texttt{index}-4 & \texttt{next}-5,\\ \texttt{index}-5 & \texttt{next}-5,\\ \texttt{index}-6 & \texttt{next}-7,\\ \texttt{index}-7 & \texttt{next}-7,\\ \texttt{index}-8 & \texttt{next}-8,\\ \texttt{index}-9 & \texttt{next}-9\end{array}\right\rangle\right)$$

Figure 5.718 gives the folded sequence associated with the previous example. Each number represents the index of an item. The SEQUENCE_FOLDING constraint holds since no crossing occurs.

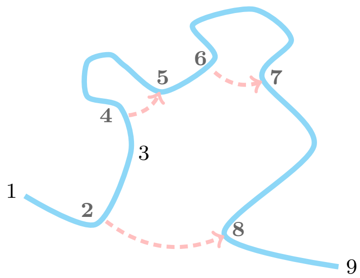
Typical
|LETTERS| > 2
range(LETTERS.next) > 1

Usage Motivated by RNA folding [178].

See also **implies (items to collection):** LEX_ALLDIFFERENT, LEX_CHAIN_LESS.

Keywords **application area:** bioinformatics.

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.



LETTERS

index − 1	next − 1
index − 2	next − 8
index − 3	next − 3
index − 4	next − 5
index − 5	next − 5
index − 6	next − 7
index − 7	next − 7
index − 8	next − 8
index − 9	next − 9

Figure 5.718: Folded sequence (in blue) of the **Example** slot: links from a letter to a distinct letter are represented by a dashed arc, while self-loops are not drawn

combinatorial object: sequence.

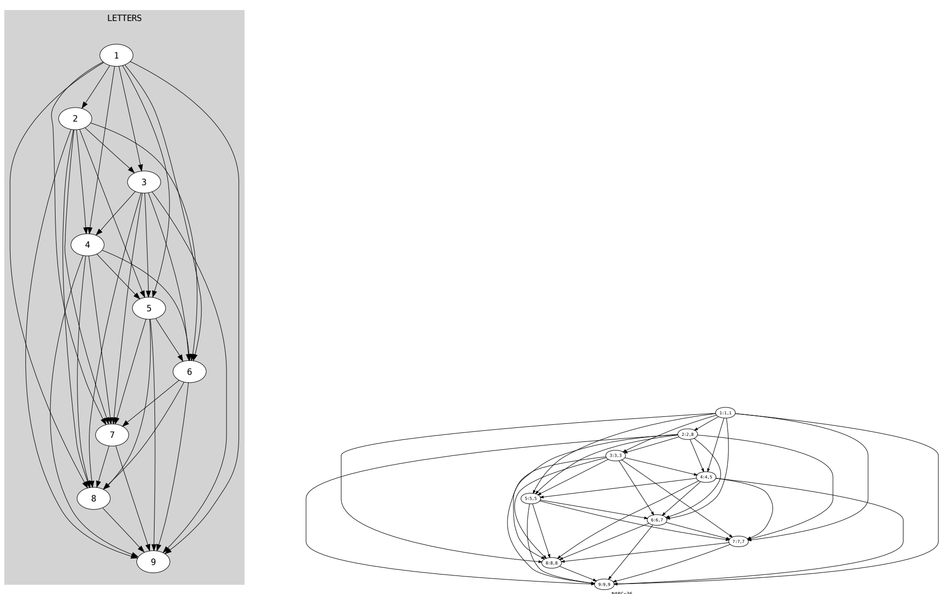
constraint type: decomposition.

geometry: geometrical constraint.

Arc input(s)	LETTERS
Arc generator	$SELF \mapsto$ collection(letters)
Arc arity	1
Arc constraint(s)	letters.next $\geq$ letters.index
Graph property(ies)	**NARC** $= \vert$LETTERS$\vert$

Arc input(s)	LETTERS
Arc generator	$CLIQUE(<) \mapsto$ collection(letters1, letters2)
Arc arity	2
Arc constraint(s)	$\bigvee\left(\begin{array}{l}\texttt{letters2.index} \geq \texttt{letters1.next},\\ \texttt{letters2.next} \leq \texttt{letters1.next}\end{array}\right)$
Graph property(ies)	**NARC** $= \vert$LETTERS$\vert * (\vert$LETTERS$\vert - 1)/2$

Graph model Parts (A) and (B) of Figure 5.719 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.



(A) **(B)**

Figure 5.719: Initial and final graph of the SEQUENCE_FOLDING constraint

Signature Consider the first graph constraint. Since we use the $SELF$ arc generator on the LETTERS collection the maximum number of arcs of the final graph is equal to $\vert$LETTERS$\vert$. Therefore we can rewrite the graph property $\mathbf{NARC} = |\texttt{LETTERS}|$ to $\mathbf{NARC} \geq |\texttt{LETTERS}|$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

Consider now the second graph constraint. Since we use the $CLIQUE(<)$ arc generator on the LETTERS collection the maximum number of arcs of the final graph is equal to $|\texttt{LETTERS}| \cdot (|\texttt{LETTERS}| - 1)/2$. Therefore we can rewrite the graph property $\mathbf{NARC} = |\texttt{LETTERS}| \cdot (|\texttt{LETTERS}| - 1)/2$ to $\mathbf{NARC} \geq |\texttt{LETTERS}| \cdot (|\texttt{LETTERS}| - 1)/2$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

Automaton Figure 5.720 depicts the automaton associated with the SEQUENCE_FOLDING constraint. Consider the i^{th} and the j^{th} $(i < j)$ items of the collection $\texttt{LETTERS}$. Let $\texttt{INDEX}_i$ and $\texttt{NEXT}_i$ respectively denote the `index` and the `next` attributes of the i^{th} item of the collection $\texttt{LETTERS}$. Similarly, let $\texttt{INDEX}_j$ and $\texttt{NEXT}_j$ respectively denote the `index` and the `next` attributes of the j^{th} item of the collection $\texttt{LETTERS}$. To each quadruple $(\texttt{INDEX}_i, \texttt{NEXT}_i, \texttt{INDEX}_j, \texttt{NEXT}_j)$ corresponds a signature variable $S_{i,j}$, which takes its value in $\{0, 1, 2\}$, as well as the following signature constraint:

$(\texttt{INDEX}_i \leq \texttt{NEXT}_i) \wedge (\texttt{INDEX}_j \leq \texttt{NEXT}_j) \wedge (\texttt{NEXT}_i \leq \texttt{NEXT}_j) \Leftrightarrow S_{i,j} = 0 \wedge$

$(\texttt{INDEX}_i \leq \texttt{NEXT}_i) \wedge (\texttt{INDEX}_j \leq \texttt{NEXT}_j) \wedge (\texttt{NEXT}_i > \texttt{INDEX}_j) \wedge (\texttt{NEXT}_j \leq \texttt{NEXT}_i) \Leftrightarrow S_{i,j} = 1$.

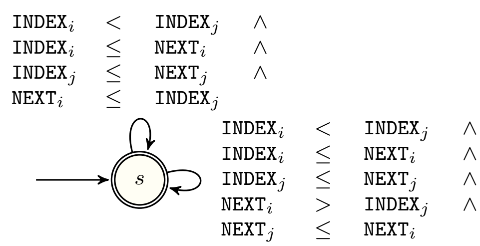


Figure 5.720: Automaton of the SEQUENCE_FOLDING constraint

5.351 SET_VALUE_PRECEDE

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin [269]

Constraint SET_VALUE_PRECEDE(S, T, VARIABLES)

Arguments

S : int
T : int
VARIABLES : collection(var−svar)

Restrictions

$\texttt{S} \neq \texttt{T}$
required(VARIABLES, var)

Purpose If there exists a set variable v_1 of VARIABLES such that S does not belong to v_1 and T does, then there also exists a set variable v_2 preceding v_1 such that S belongs to v_2 and T does not.

Example

$(2, 1, \langle \texttt{var} - \{0, 2\}, \texttt{var} - \{0, 1\}, \texttt{var} - \emptyset, \texttt{var} - \{1\}\rangle)$
$(0, 1, \langle \texttt{var} - \{0, 2\}, \texttt{var} - \{0, 1\}, \texttt{var} - \emptyset, \texttt{var} - \{1\}\rangle)$
$(0, 2, \langle \texttt{var} - \{0, 2\}, \texttt{var} - \{0, 1\}, \texttt{var} - \emptyset, \texttt{var} - \{1\}\rangle)$
$(0, 4, \langle \texttt{var} - \{0, 2\}, \texttt{var} - \{0, 1\}, \texttt{var} - \emptyset, \texttt{var} - \{1\}\rangle)$

The following examples are taken from [268, page 58]:

- The SET_VALUE_PRECEDE$(2, 1, \langle\{0, 2\}, \{0, 1\}, \{\}, \{1\}\rangle)$ constraint holds since the first occurrence of value 2 precedes the first occurrence of value 1 (i.e., the set $\{0, 2\}$ occurs before the set $\{0, 1\}$).
- The SET_VALUE_PRECEDE$(0, 1, \langle\{0, 2\}, \{0, 1\}, \{\}, \{1\}\rangle)$ constraint holds since the first occurrence of value 0 precedes the first occurrence of value 1 (i.e., the set $\{0, 2\}$ occurs before the set $\{0, 1\}$).
- The SET_VALUE_PRECEDE$(0, 2, \langle\{0, 2\}, \{0, 1\}, \{\}, \{1\}\rangle)$ constraint holds since "there is no set in $\langle\{0, 2\}, \{0, 1\}, \{\}, \{1\}\rangle$ that contains 2 but not 0".
- The SET_VALUE_PRECEDE$(0, 4, \langle\{0, 2\}, \{0, 1\}, \{\}, \{1\}\rangle)$ constraint holds since no set in $\langle\{0, 2\}, \{0, 1\}, \{\}, \{1\}\rangle$ contains value 4.

Typical

$\texttt{S} < \texttt{T}$
$|\texttt{VARIABLES}| > 1$

Arg. properties Suffix-contractible wrt. VARIABLES.

Algorithm A filtering algorithm for maintaining value precedence on a sequence of set variables is presented in [269]. Its complexity is linear to the number of variables of the collection VARIABLES.

Systems PRECEDE in **Gecode**.

See also **specialisation:** INT_VALUE_PRECEDE *(*`sequence` *of* `set variables` *replaced by* `sequence` *of* `domain variables`*)*.

Keywords **constraint arguments:** constraint involving set variables.

constraint type: order constraint.

symmetry: symmetry, indistinguishable values, value precedence.

5.352 SHIFT

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint $\text{SHIFT}(\texttt{MIN\_BREAK}, \texttt{MAX\_RANGE}, \texttt{TASKS})$

Arguments

$\texttt{MIN\_BREAK} : \texttt{int}$
$\texttt{MAX\_RANGE} : \texttt{int}$
$\texttt{TASKS} : \texttt{collection}(\texttt{origin}-\texttt{dvar}, \texttt{end}-\texttt{dvar})$

Restrictions

$\texttt{MIN\_BREAK} > 0$
$\texttt{MAX\_RANGE} > 0$
$\texttt{required}(\texttt{TASKS}, [\texttt{origin}, \texttt{end}])$
$\texttt{TASKS.origin} < \texttt{TASKS.end}$

Purpose

The difference between the end of the last task of a *shift* and the origin of the first task of a *shift* should not exceed the quantity MAX_RANGE. Two tasks t_1 and t_2 belong to the *same shift* if at least one of the following conditions is true:

- Task t_2 starts after the end of task t_1 at a distance that is less than or equal to the quantity MIN_BREAK,
- Task t_1 starts after the end of task t_2 at a distance that is less than or equal to the quantity MIN_BREAK.
- Task t_1 overlaps task t_2.

Example

$$\left(6, 8, \left\langle \begin{array}{ll} \texttt{origin}-17 & \texttt{end}-20, \\ \texttt{origin}-7 & \texttt{end}-10, \\ \texttt{origin}-2 & \texttt{end}-4, \\ \texttt{origin}-21 & \texttt{end}-22, \\ \texttt{origin}-5 & \texttt{end}-6 \end{array} \right\rangle \right)$$

Figure 5.721 represents the different tasks of the example. Each task is drawn as a rectangle with its corresponding id attribute in the middle. We indicate the distance between two consecutive tasks of a same shift and note that it is less than or equal to $\texttt{MIN\_BREAK} = 6$. Since each shift has a range that is less than or equal to $\texttt{MAX\_RANGE} = 8$, the SHIFT constraint holds (the *range* of a shift is the difference between the end of the last task of the shift and the origin of the first task of the shift).

All solutions

Figure 5.722 gives all solutions to the following non ground instance of the SHIFT constraint: $\texttt{MIN\_BREAK} = 2$, $\texttt{MAX\_RANGE} = 5$, $\texttt{O}_1 \in [1, 2]$, $\texttt{E}_1 \in [1, 4]$, $\texttt{O}_2 \in [1, 4]$, $\texttt{E}_2 \in [1, 2]$, $\texttt{O}_3 \in [4, 7]$, $\texttt{E}_3 \in [4, 5]$, $\texttt{O}_4 \in [7, 9]$, $\texttt{E}_4 \in [0, 9]$, $\text{SHIFT}(\texttt{MIN\_BREAK}, \texttt{MAX\_RANGE}, \langle \texttt{O}_1\ \texttt{E}_1, \texttt{O}_2\ \texttt{E}_2, \texttt{O}_3\ \texttt{E}_3, \texttt{O}_4\ \texttt{E}_4 \rangle)$.

TASKS

①	`origin` − 17	`end` − 20	④	`origin` − 21	`end` − 22
②	`origin` − 7	`end` − 10	⑤	`origin` − 5	`end` − 6
③	`origin` − 2	`end` − 4			

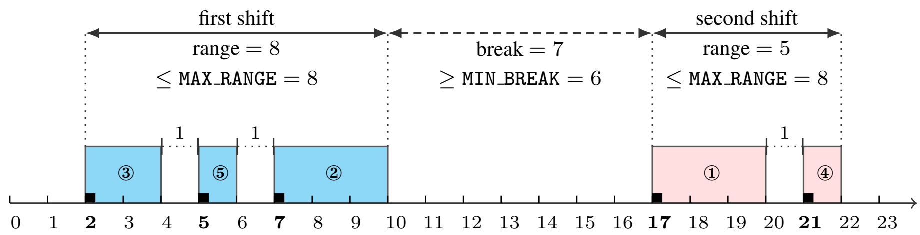

Figure 5.721: The two shifts of the **Example** slot

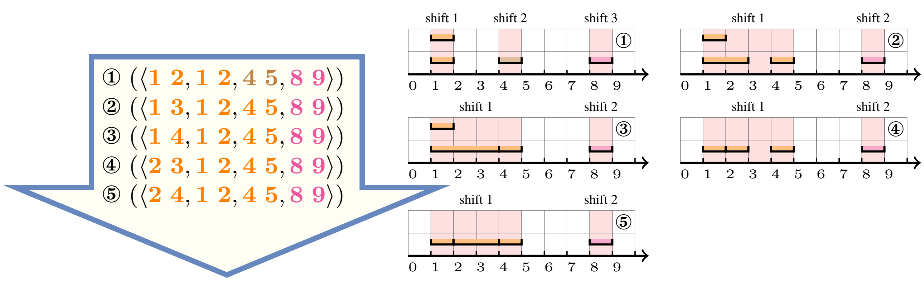

Figure 5.722: All solutions corresponding to the non ground example of the SHIFT constraint of the **All solutions** slot, where tasks belonging to the same shift are coloured with the same colour

Typical

$\texttt{MIN\_BREAK} > 1$
$\texttt{MAX\_RANGE} > 1$
$\texttt{MIN\_BREAK} < \texttt{MAX\_RANGE}$
$|\texttt{TASKS}| > 2$

Symmetries

- Items of TASKS are permutable.
- One and the same constant can be added to the `origin` attribute of all items of TASKS.

Usage

The shift constraint can be used in machine scheduling problems where one has to shut down a machine for maintenance purpose after a given maximum utilisation of that machine. In this case the MAX_RANGE parameter indicates the maximum possible utilisation of the machine before maintenance, while the MIN_BREAK parameter gives the minimum time needed for maintenance.

The shift constraint can also be used for timetabling problems where the rest period of a person can move in time. In this case MAX_RANGE indicates the maximum possible working time for a person, while `MIN_BREAK` specifies the minimum length of the break that follows a working time period.

See also **common keyword:** SLIDING_TIME_WINDOW *(temporal constraint)*.

used in graph description: RANGE_CTR.

Keywords **constraint type:** scheduling constraint, timetabling constraint, temporal constraint.

Arc input(s)	TASKS
Arc generator	$SELF \mapsto$ collection(tasks)
Arc arity	1
Arc constraint(s)	• tasks.end $\geq$ tasks.origin • tasks.end $-$ tasks.origin $\leq$ MAX_RANGE
Graph property(ies)	**NARC** $=$ |TASKS|

Arc input(s)	TASKS
Arc generator	$CLIQUE \mapsto$ collection(tasks1, tasks2)
Arc arity	2
Arc constraint(s)	$\bigvee\left(\begin{array}{l}\bigwedge\left(\begin{array}{l}\texttt{tasks2.origin} \geq \texttt{tasks1.end},\\ \texttt{tasks2.origin} - \texttt{tasks1.end} \leq \texttt{MIN\_BREAK}\end{array}\right),\\ \bigwedge\left(\begin{array}{l}\texttt{tasks1.origin} \geq \texttt{tasks2.end},\\ \texttt{tasks1.origin} - \texttt{tasks2.end} \leq \texttt{MIN\_BREAK}\end{array}\right),\\ \bigwedge\left(\begin{array}{l}\texttt{tasks2.origin} < \texttt{tasks1.end},\\ \texttt{tasks1.origin} < \texttt{tasks2.end}\end{array}\right)\end{array}\right)$
Sets	$\mathsf{CC} \mapsto \left[\texttt{variables} - \texttt{col}\left(\begin{array}{l}\texttt{VARIABLES}-\texttt{collection}(\texttt{var}-\texttt{dvar}),\\ \left[\begin{array}{l}\texttt{item}(\texttt{var} - \texttt{TASKS.origin}),\\ \texttt{item}(\texttt{var} - \texttt{TASKS.end})\end{array}\right]\end{array}\right)\right]$
Constraint(s) on sets	RANGE_CTR(variables, $\leq$, MAX_RANGE)

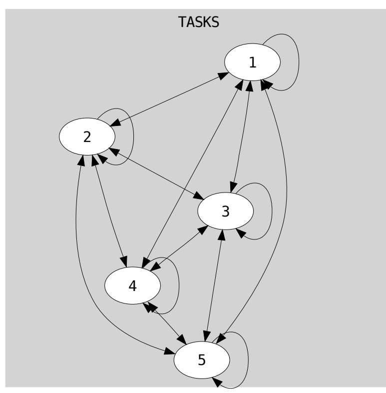
Graph model The first graph constraint forces the following two constraints between the attributes of each task:

- The end of a task should not be situated before its start,
- The duration of a task should not be greater than the MAX_RANGE parameter.

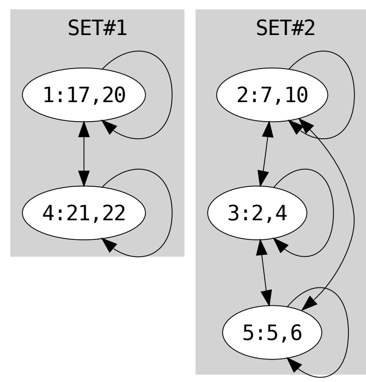
The second graph constraint decomposes the final graph in connected components where each component corresponds to a given shift. Finally, the **Constraint(s) on sets** slot restricts the stretch of each shift.

Parts (A) and (B) of Figure 5.723 respectively show the initial and final graph associated with the second graph constraint of the **Example** slot. Since we use the set generator CC we show the two connected components of the final graph. They respectively correspond to the two shifts that are displayed in Figure 5.721.

Signature Consider the first graph constraint. Since we use the $SELF$ arc generator on the TASKS collection the maximum number of arcs of the final graph is equal to |TASKS|. Therefore we can rewrite the graph property $\mathbf{NARC} = |\texttt{TASKS}|$ to $\mathbf{NARC} \geq |\texttt{TASKS}|$ and simplify $\underline{\mathbf{NARC}}$ to $\overline{\mathbf{NARC}}$.



(A)



(B)

Figure 5.723: Initial and final graph of the SHIFT constraint

5.353 SIGN_OF

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic.

Constraint SIGN_OF(S, X)

Usual name SIGN

Arguments

S : dvar
X : dvar

Restrictions

$S \geq -1$
$S \leq 1$

Purpose

According to the value of the first variable S, restrict the sign of the second variable X:

- When $S = -1$, X should be negative (i.e., $X < 0$).
- When $S = 0$, X is also equal to 0.
- When $S = +1$, X should be positive (i.e., $X > 0$).

Example

$(-1, -8)$
$(0, 0)$
$(1, 8)$

- The first SIGN_OF constraint holds since $S = -1$ and $X = -8$ is negative.
- The second SIGN_OF constraint holds since $S = 0$ and $X = 0$ is neither negative, neither positive.
- The second SIGN_OF constraint holds since $S = +1$ and $X = 8$ is positive.

Typical

$S \neq 0$
$X \neq 0$

Arg. properties Functional dependency: S determined by X.

See also **implies:** SAME_SIGN, ZERO_OR_NOT_ZERO.

Keywords

constraint arguments: binary constraint, pure functional dependency.

constraint type: predefined constraint, arithmetic constraint.

filtering: arc-consistency.

modelling: functional dependency.

5.354 SIZE_MAX_SEQ_ALLDIFFERENT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint SIZE_MAX_SEQ_ALLDIFFERENT(SIZE, VARIABLES)

Synonyms SIZE_MAXIMAL_SEQUENCE_ALLDIFF, SIZE_MAXIMAL_SEQUENCE_ALLDISTINCT, SIZE_MAXIMAL_SEQUENCE_ALLDIFFERENT.

Arguments

SIZE	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

SIZE ≥ 0
SIZE $\leq$ |VARIABLES|
required(VARIABLES, var)

Purpose SIZE is the size of the maximal sequence (among all possible sequences of consecutive variables of the collection VARIABLES) for which the ALLDIFFERENT constraint holds.

Example

$(4, \langle 2, 2, 4, 5, 2, 7, 4\rangle)$
$(1, \langle 2, 2, 2, 2, 2, 2, 2\rangle)$
$(2, \langle 2, 2, 4, 4, 4, 7, 4\rangle)$
$(7, \langle 2, 0, 4, 6, 5, 7, 3\rangle)$

The first SIZE_MAX_SEQ_ALLDIFFERENT constraint holds since the constraint ALLDIFFERENT($\langle$var − 4, var − 5, var − 2, var − 7$\rangle$) holds and since the following three constraints do not hold:

- ALLDIFFERENT($\langle$var − 2, var − 2, var − 4, var − 5, var − 2$\rangle$),
- ALLDIFFERENT($\langle$var − 2, var − 4, var − 5, var − 2, var − 7$\rangle$),
- ALLDIFFERENT($\langle$var − 4, var − 5, var − 2, var − 7, var − 4$\rangle$).

Typical

SIZE > 2
SIZE $<$ |VARIABLES|
range(VARIABLES.var) > 1

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: SIZE determined by VARIABLES.

Counting

5.355 SIZE_MAX_STARTING_SEQ_ALLDIFFERENT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Inspired by SIZE_MAX_SEQ_ALLDIFFERENT.

Constraint SIZE_MAX_STARTING_SEQ_ALLDIFFERENT(SIZE, VARIABLES)

Synonyms SIZE_MAXIMAL_STARTING_SEQUENCE_ALLDIFF, SIZE_MAXIMAL_STARTING_SEQUENCE_ALLDISTINCT, SIZE_MAXIMAL_STARTING_SEQUENCE_ALLDIFFERENT.

Arguments

SIZE : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\texttt{SIZE} \geq 0$
$\texttt{SIZE} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose SIZE is the size of the maximal sequence (among all sequences of consecutive variables of the collection VARIABLES starting at position one) for which the ALLDIFFERENT constraint holds.

Example

$(4, \langle 9, 2, 4, 5, 2, 7, 4\rangle)$
$(7, \langle 9, 2, 4, 5, 1, 7, 8\rangle)$
$(6, \langle 9, 2, 4, 5, 1, 7, 9\rangle)$

The first SIZE_MAX_STARTING_SEQ_ALLDIFFERENT constraint holds since the constraint ALLDIFFERENT($\langle$var − 9, var − 2, var − 4, var − 5$\rangle$) holds and since ALLDIFFERENT($\langle$var − 9, var − 2, var − 4, var − 5, var − 2$\rangle$) does not hold.

Typical

$\texttt{SIZE} > 2$
$\texttt{SIZE} < |\texttt{VARIABLES}|$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$

Symmetry One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties Functional dependency: SIZE determined by VARIABLES.

Remark A conditional constraint [296] with the specific structure that one can relax the constraints on the last variables of the collection VARIABLES.

5.356 SLIDING_CARD_SKIP0

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin N. Beldiceanu

Constraint SLIDING_CARD_SKIP0(ATLEAST, ATMOST, VARIABLES, VALUES)

Arguments

ATLEAST : int
ATMOST : int
VARIABLES : collection(var−dvar)
VALUES : collection(val−int)

Restrictions

ATLEAST ≥ 0
ATLEAST $\leq$ |VARIABLES|
ATMOST ≥ 0
ATMOST $\leq$ |VARIABLES|
ATMOST $\geq$ ATLEAST
required(VARIABLES, var)
required(VALUES, val)
distinct(VALUES, val)
VALUES.val $\neq 0$

Purpose

Let n be the total number of variables of the collection VARIABLES. A *maximum non-zero set of consecutive variables* $X_i..X_j (1 \leq i \leq j \leq n)$ is defined in the following way:

- All variables $X_i, \ldots, X_j$ take a non-zero value,
- $i = 1$ or X_{i-1} is equal to 0,
- $j = n$ or X_{j+1} is equal to 0.

Enforces that each maximum non-zero set of consecutive variables of the collection VARIABLES contains at least ATLEAST and at most ATMOST values from the collection of values VALUES.

Example

$(2, 3, \langle 0, 7, 2, 9, 0, 0, 9, 4, 9 \rangle, \langle 7, 9 \rangle)$

The SLIDING_CARD_SKIP0 constraint holds since the two maximum non-zero set of consecutive values 7 2 9 and 9 4 9 of its third argument $\langle 0, 7, 2, 9, 0, 0, 9, 4, 9 \rangle$ take both 2 ($2 \in$ [ATLEAST, ATMOST] $= [2, 3]$) values within the set of values $\langle 7, 9 \rangle$.

Typical

|VARIABLES| > 1
|VALUES| > 0
|VARIABLES| $>$ |VALUES|
ATLEAST(1, VARIABLES, 0)
ATLEAST $> 0 \vee$ ATMOST $<$ |VARIABLES|

Symmetries

- ATLEAST can be decreased to any value ≥ 0.
- ATMOST can be increased to any value $\leq$ |VARIABLES|.
- Items of VARIABLES can be reversed.
- An occurrence of a value different from 0 of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value different from 0 in VALUES.val (resp. not in VALUES.val).

Usage

This constraint is useful in timetabling problems where the variables are interpreted as the type of job that a person does on consecutive days. Value 0 represents a rest day and one imposes a cardinality constraint on periods that are located between rest periods.

Remark

One cannot initially state a GLOBAL_CARDINALITY constraint since the rest days are not yet allocated. One can also not use an AMONG_SEQ constraint since it does not hold for the sequences of consecutive variables that contains at least one rest day.

See also

related: AMONG *(counting constraint on the full sequence)*, GLOBAL_CARDINALITY *(counting constraint for different values on the full sequence)*.

specialisation: AMONG_LOW_UP *(maximal sequences replaced by the full sequence)*.

Keywords

characteristic of a constraint: automaton, automaton with counters.

combinatorial object: sequence.

constraint network structure: alpha-acyclic constraint network(2).

constraint type: timetabling constraint, sliding sequence constraint.

Arc input(s)	VARIABLES
Arc generator	$PATH \mapsto$ collection(variables1, variables2) $LOOP \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	• variables1.var $\neq 0$ • variables2.var $\neq 0$
Sets	CC $\mapsto$ [variables]
Constraint(s) on sets	AMONG_LOW_UP(ATLEAST, ATMOST, variables, VALUES)

Graph model Note that the arc constraint will produce the different sequences of consecutive variables that do not contain any 0. The CC set generator produces all the connected components of the final graph.

Parts (A) and (B) of Figure 5.725 respectively show the initial and final graph associated with the **Example** slot. Since we use the set generator CC we show the two connected components of the final graph. Since these two connected components both contains between 2 and 3 variables that take their values in $\{7, 9\}$ the SLIDING_CARD_SKIP0 constraint holds.

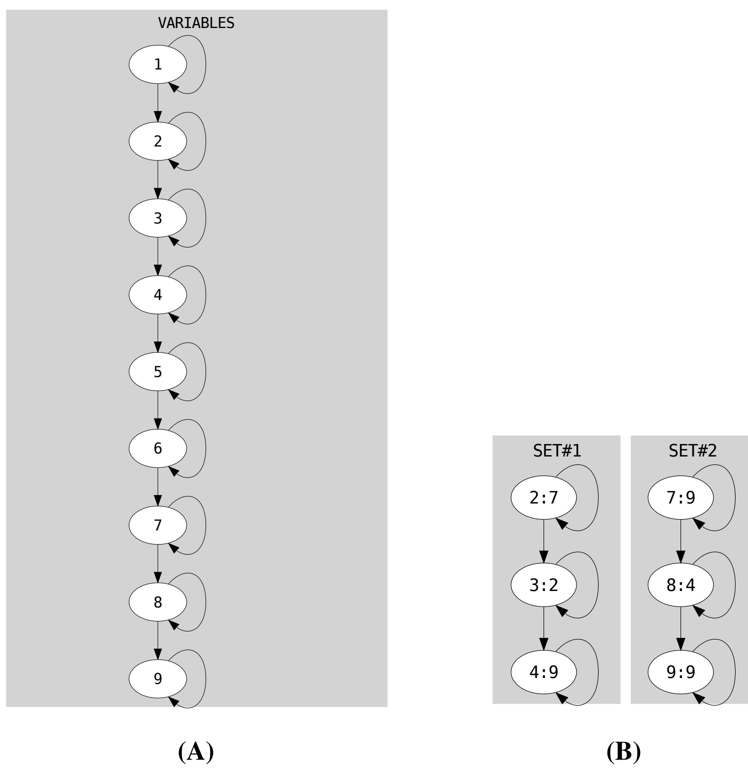

Figure 5.725: Initial and final graph of the SLIDING_CARD_SKIP0 constraint

Automaton Figure 5.726 depicts the automaton associated with the SLIDING_CARD_SKIP0 constraint. To each variable $\texttt{VAR}_i$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\texttt{VAR}_i$ and S_i:

$(\texttt{VAR}_i = 0) \Leftrightarrow S_i = 0 \wedge$

$(\texttt{VAR}_i \neq 0 \wedge \texttt{VAR}_i \notin \texttt{VALUES}) \Leftrightarrow S_i = 1 \wedge$

$(\texttt{VAR}_i \neq 0 \wedge \texttt{VAR}_i \in \texttt{VALUES}) \Leftrightarrow S_i = 2.$

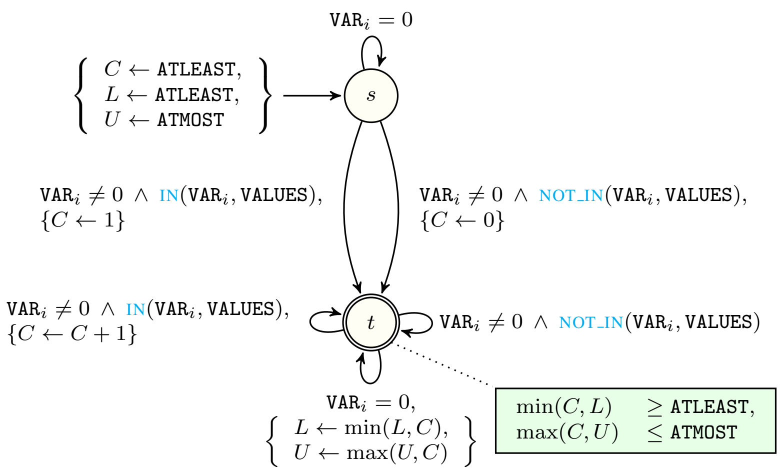

Figure 5.726: Automaton of the SLIDING_CARD_SKIP0 constraint

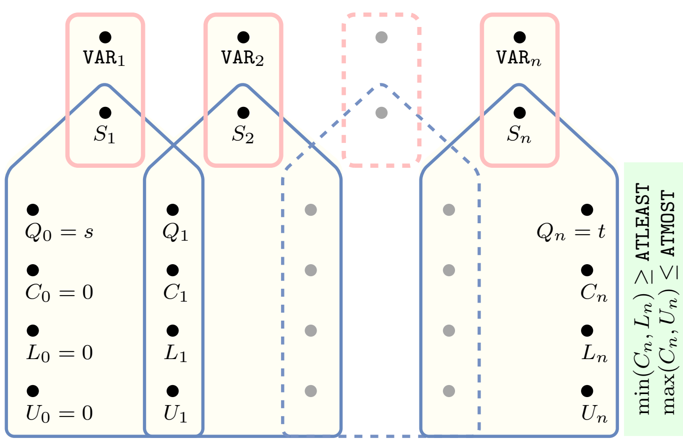

Figure 5.727: Hypergraph of the reformulation corresponding to the automaton of the SLIDING_CARD_SKIP0 constraint

5.357 SLIDING_DISTRIBUTION

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [362]

Constraint SLIDING_DISTRIBUTION(SEQ, VARIABLES, VALUES)

Arguments

SEQ	:	int
VARIABLES	:	collection(var−dvar)
VALUES	:	collection(val−int, omin−int, omax−int)

Restrictions

SEQ >0
SEQ $\leq$ |VARIABLES|
required(VARIABLES, var)
|VALUES| >0
required(VALUES, [val, omin, omax])
distinct(VALUES, val)
VALUES.omin ≥ 0
VALUES.omax $\leq$ SEQ
VALUES.omin $\leq$ VALUES.omax

Purpose

For each sequence of SEQ consecutive variables of the VARIABLES collection, each value VALUES$[i]$.val ($1 \leq i \leq$ |VALUES|) should be taken by at least VALUES$[i]$.omin and at most VALUES$[i]$.omax variables.

Example

$$\left(\begin{array}{l} 4, \langle 0,5,0,6,5,0,0\rangle, \\ \left\langle\begin{array}{lll} \text{val}-0 & \text{omin}-1 & \text{omax}-2, \\ \text{val}-1 & \text{omin}-0 & \text{omax}-4, \\ \text{val}-4 & \text{omin}-0 & \text{omax}-4, \\ \text{val}-5 & \text{omin}-1 & \text{omax}-2, \\ \text{val}-6 & \text{omin}-0 & \text{omax}-2 \end{array}\right\rangle \end{array}\right)$$

The SLIDING_DISTRIBUTION constraint holds since:

- On the first sequence of 4 consecutive values 0 5 0 6 values 0, 1, 4, 5 and 6 are respectively used 2, 0, 0, 1 and 1 times.
- On the second sequence of 4 consecutive values 5 0 6 5 values 0, 1, 4, 5 and 6 are respectively used 1, 0, 0, 2 and 1 times.
- On the third sequence of 4 consecutive values 0 6 5 0 values 0, 1, 4, 5 and 6 are respectively used 2, 0, 0, 1 and 1 times.
- On the fourth sequence of 4 consecutive values 6 5 0 0 values 0, 1, 4, 5 and 6 are respectively used 2, 0, 0, 1 and 1 times.

Typical

SEQ >1
SEQ $<$ |VARIABLES|
|VARIABLES| $>$ |VALUES|

Symmetries

- Items of VARIABLES can be reversed.
- An occurrence of a value of VARIABLES.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.
- Items of VALUES are permutable.
- VALUES.omin can be decreased to any value ≥ 0.
- VALUES.omax can be increased to any value $\leq$ SEQ.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.

Arg. properties

- Contractible wrt. VARIABLES when SEQ $= 1$.
- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.
- Contractible wrt. VALUES.

specialisation: AMONG_SEQ *(individual values replaced by single set of values)*.

used in graph description: GLOBAL_CARDINALITY_LOW_UP.

Keywords

characteristic of a constraint: hypergraph.

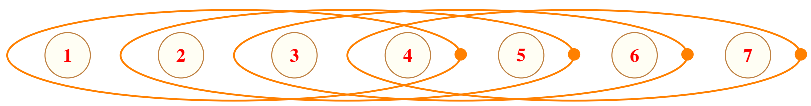
combinatorial object: sequence.

constraint type: decomposition, sliding sequence constraint, system of constraints.

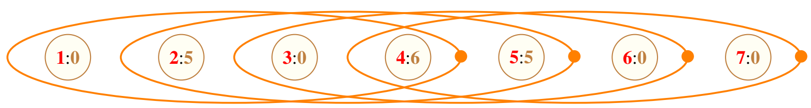
Arc input(s)	VARIABLES
Arc generator	$PATH \mapsto$ collection
Arc arity	SEQ
Arc constraint(s)	GLOBAL_CARDINALITY_LOW_UP(collection, VALUES)
Graph property(ies)	**NARC** $= \vert$VARIABLES$\vert -$ SEQ $+ 1$

Graph model Note that the SLIDING_DISTRIBUTION constraint is a constraint where the arc constraints do not have an arity of 2.

Parts (A) and (B) of Figure 5.728 respectively show the initial and final graph associated with the **Example** slot. Since all arc constraints hold (i.e., because of the graph property **NARC** $= \vert$VARIABLES$\vert -$ SEQ $+ 1$) the final graph corresponds to the initial graph.



(A)



(B)

Figure 5.728: (A) Initial and (B) final graph of the SLIDING_DISTRIBUTION($4, \langle 0, 5, 0, 6, 5, 0, 0\rangle, \langle 0\ 1\ 2,\ 1\ 0\ 4,\ 4\ 0\ 4,\ 5\ 1\ 2,\ 6\ 0\ 2\rangle$) constraint of the **Example** slot where each ellipse represents an hyperedge involving SEQ $= 4$ vertices (to each ellipse corresponds a GLOBAL_CARDINALITY_LOW_UP constraint)

5.358 SLIDING_SUM

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin CHIP

Constraint SLIDING_SUM(LOW, UP, SEQ, VARIABLES)

Synonym SEQUENCE.

Arguments

LOW	:	int
UP	:	int
SEQ	:	int
VARIABLES	:	collection(var−dvar)

Restrictions

$\texttt{UP} \geq \texttt{LOW}$
$\texttt{SEQ} > 0$
$\texttt{SEQ} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose Constrains all sequences of SEQ consecutive variables of the collection VARIABLES so that the sum of the variables belongs to interval [LOW, UP].

Example $(3, 7, 4, \langle 1, 4, 2, 0, 0, 3, 4\rangle)$

The example considers all sliding sequences of SEQ $=$ 4 consecutive values of $\langle 1, 4, 2, 0, 0, 3, 4\rangle$ collection and constraints the sum to be in [LOW, UP] $= [3, 7]$. The SLIDING_SUM constraint holds since the sum associated with the corresponding subsequences 1 4 2 0, 4 2 0 0, 2 0 0 3, and 0 0 3 4 are respectively 7, 6, 5 and 7.

Typical

$\texttt{LOW} \geq 0$
$\texttt{UP} > 0$
$\texttt{SEQ} > 1$
$\texttt{SEQ} < |\texttt{VARIABLES}|$
$\texttt{VARIABLES.var} \geq 0$
$\texttt{UP} < \texttt{sum}(\texttt{VARIABLES.var})$

Symmetry Items of VARIABLES can be reversed.

Arg. properties

- Contractible wrt. VARIABLES when SEQ $= 1$.
- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Algorithm Beldiceanu and Carlsson [32] have proposed a first incomplete filtering algorithm for the SLIDING_SUM constraint. In 2008, Maher *et al.* showed in [284] that the SLIDING_SUM constraint has a solution "*if and only there are no negative cycles in the flow graph associated with the dual linear program*" that encodes the conjunction of inequalities. They derive a bound-consistency filtering algorithm from this fact.

Systems SLIDING_SUM in **MiniZinc**.

See also **common keyword:** SLIDING_DISTRIBUTION *(sliding sequence constraint)*.

part of system of constraints: SUM_CTR.

soft variant: RELAXED_SLIDING_SUM.

used in graph description: SUM_CTR.

Keywords **characteristic of a constraint:** hypergraph, sum.

combinatorial object: sequence.

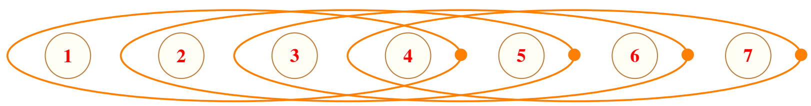
constraint type: decomposition, sliding sequence constraint, system of constraints.

filtering: linear programming, flow, bound-consistency.

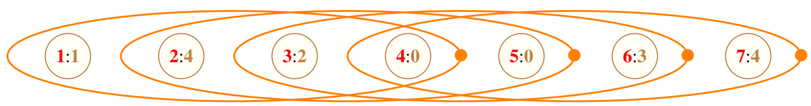
Arc input(s)	VARIABLES
Arc generator	$PATH \mapsto$ collection
Arc arity	SEQ
Arc constraint(s)	• SUM_CTR(collection, $\geq$, LOW) • SUM_CTR(collection, $\leq$, UP)
Graph property(ies)	$\mathbf{NARC} = \lvert \mathtt{VARIABLES} \rvert - \mathtt{SEQ} + 1$

Graph model We use SUM_CTR as an arc constraint. SUM_CTR takes a collection of domain variables as its first argument.

Parts (A) and (B) of Figure 5.729 respectively show the initial and final graph associated with the **Example** slot. Since all arc constraints hold (i.e., because of the graph property $\mathbf{NARC} = \lvert \mathtt{VARIABLES} \rvert - \mathtt{SEQ} + 1$) the final graph corresponds to the initial graph.



(A)



(B)

Figure 5.729: (A) Initial and (B) final graph of the SLIDING_SUM$(3, 7, 4, \langle 1, 4, 2, 0, 0, 3, 4\rangle)$ constraint of the **Example** slot where each ellipse represents an hyperedge involving $\mathtt{SEQ} = 4$ vertices (e.g., the first ellipse represents the constraint $1 + 4 + 2 + 0 \in [3, 7]$)

Signature Since we use the $PATH$ arc generator with an arity of SEQ on the items of the VARIABLES collection, the expression $\lvert \mathtt{VARIABLES} \rvert - \mathtt{SEQ} + 1$ corresponds to the maximum number of arcs of the final graph. Therefore we can rewrite the graph property $\mathbf{NARC} = \lvert \mathtt{VARIABLES} \rvert - \mathtt{SEQ} + 1$ to $\mathbf{NARC} \geq \lvert \mathtt{VARIABLES} \rvert - \mathtt{SEQ} + 1$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.359 SLIDING_TIME_WINDOW

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint SLIDING_TIME_WINDOW(WINDOW_SIZE, LIMIT, TASKS)

Arguments

WINDOW_SIZE : int
LIMIT : int
TASKS : collection(origin−dvar, duration−dvar)

Restrictions

WINDOW_SIZE > 0
LIMIT ≥ 0
required(TASKS, [origin, duration])
TASKS.duration ≥ 0

Purpose For any time window of size WINDOW_SIZE, the intersection of all the tasks of the collection TASKS with this time window is less than or equal to a given limit LIMIT.

Example

$$\left(9, 6, \left\langle \begin{array}{ll} \texttt{origin}-10 & \texttt{duration}-3, \\ \texttt{origin}-5 & \texttt{duration}-1, \\ \texttt{origin}-6 & \texttt{duration}-2, \\ \texttt{origin}-14 & \texttt{duration}-2, \\ \texttt{origin}-2 & \texttt{duration}-2 \end{array} \right\rangle \right)$$

The lower part of Figure 5.730 indicates the different tasks on the time axis. Each task is drawn as a rectangle with its corresponding identifier in the middle. Finally the upper part of Figure 5.730 shows the different time windows and the respective contribution of the tasks in these time windows. Note that we only need to focus on those time windows starting at the start of one of the tasks. A line with two arrows depicts each time window. The two arrows indicate the start and the end of the time window. At the left of each time window we give its occupation. Since this occupation is always less than or equal to the limit 6, the SLIDING_TIME_WINDOW constraint holds.

Typical

WINDOW_SIZE > 1
LIMIT > 0
LIMIT $<$ sum(TASKS.duration)
$|$TASKS$| > 1$
TASKS.duration > 0

Symmetries

- WINDOW_SIZE can be decreased.
- LIMIT can be increased.
- Items of TASKS are permutable.
- One and the same constant can be added to the origin attribute of all items of TASKS.
- TASKS.duration can be decreased to any value ≥ 0.

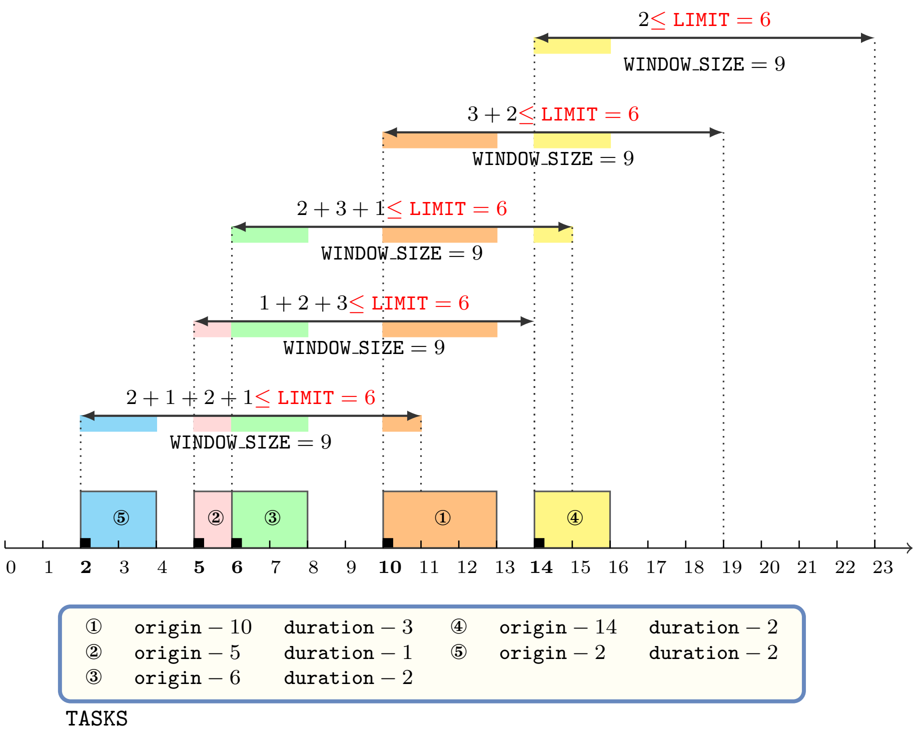


Figure 5.730: Time windows and their uses for the five tasks of the **Example** slot

Arg. properties Contractible wrt. TASKS.

Usage The SLIDING_TIME_WINDOW constraint is useful for timetabling problems in order to put an upper limit on the total work over sliding time windows.

Reformulation The SLIDING_TIME_WINDOW constraint can be expressed in term of a set of $|\text{TASKS}|^2$ reified constraints and of $|\text{TASKS}|$ linear inequalities constraints:

1. For each pair of tasks $\text{TASKS}[i], \text{TASKS}[j]$ $(i, j \in [1, |\text{TASKS}|])$ of the TASKS collection we create a variable $Inter_{ij}$ which is set to the intersection of $\text{TASKS}[j]$ with the time window $\mathcal{W}_i$ of size WINDOW_SIZE that starts at instant $\text{TASKS}[i].\text{origin}$:
   - If $i = j$ (i.e., $\text{TASKS}[i]$ and $\text{TASKS}[j]$ coincide):
     - $Inter_{ij} = \min(\text{TASKS}[i].\text{duration}, \text{WINDOW\_SIZE})$.
   - If $i \neq j$ and $\overline{\text{TASKS}[j].\text{origin}} + \overline{\text{TASKS}[j].\text{duration}} < \underline{\text{TASKS}[i].\text{origin}}$ (i.e., $\text{TASKS}[j]$ for sure ends before the time window $\mathcal{W}_i$):
     - $Inter_{ij} = 0$.
   - If $i \neq j$ and $\underline{\text{TASKS}[j].\text{origin}} > \overline{\text{TASKS}[i].\text{origin}} + \text{WINDOW\_SIZE} - 1$ (i.e., $\text{TASKS}[j]$ for sure starts after the time window $\mathcal{W}_i$):
     - $Inter_{ij} = 0$.
   - Otherwise (i.e., $\text{TASKS}[j]$ can potentially overlap the time window $\mathcal{W}_i$):

- $Inter_{ij} = \max(0, \min(\texttt{TASKS}[i].\texttt{origin} + \texttt{WINDOW\_SIZE}, \texttt{TASKS}[j].\texttt{origin} + \texttt{TASKS}[j].\texttt{duration}) - \max(\texttt{TASKS}[i].\texttt{origin}, \texttt{TASKS}[j].\texttt{origin}))$.

2. For each task $\texttt{TASKS}[i]$ $(i \in [1, |\texttt{TASKS}|])$ we create a linear inequality constraint $Inter_{i1} + Inter_{i2} + \cdots + Inter_{i|\texttt{TASKS}|} \leq \texttt{LIMIT}$.

See also

common keyword: SHIFT *(temporal constraint)*.

related: SLIDING_TIME_WINDOW_SUM *(sum of intersections of tasks with sliding time window replaced by sum of the points of intersecting tasks with sliding time window)*.

used in graph description: SLIDING_TIME_WINDOW_FROM_START.

Keywords

constraint type: sliding sequence constraint, temporal constraint.

Arc input(s)	TASKS
Arc generator	$CLIQUE \mapsto$ collection(tasks1, tasks2)
Arc arity	2
Arc constraint(s)	• tasks1.origin $\leq$ tasks2.origin • tasks2.origin $-$ tasks1.origin $<$ WINDOW_SIZE
Sets	SUCC $\mapsto$ [source, tasks]
Constraint(s) on sets	SLIDING_TIME_WINDOW_FROM_START(WINDOW_SIZE, LIMIT, tasks, source.origin)

Graph model We generate an arc from a task t_1 to a task t_2 if task t_2 does not start before task t_1 and if task t_2 intersects the time window that starts at the origin of task t_1. Each set generated by SUCC corresponds to all tasks that intersect in time the time window that starts at the origin of a given task.

Parts (A) and (B) of Figure 5.731 respectively show the initial and final graph associated with the **Example** slot. In the final graph, the successors of a given task t correspond to the set of tasks that do not start before task t and intersect the time window that starts at the origin of task t.

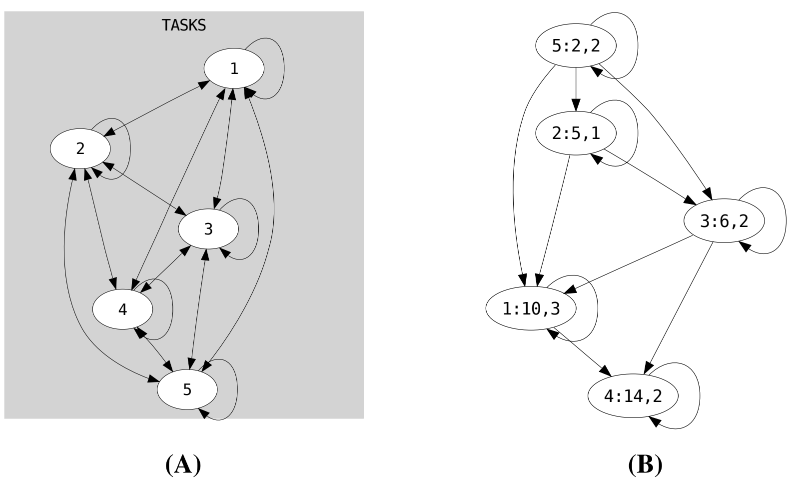

Figure 5.731: Initial and final graph of the SLIDING_TIME_WINDOW constraint

5.360 SLIDING_TIME_WINDOW_FROM_START

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Used for defining SLIDING_TIME_WINDOW.

Constraint SLIDING_TIME_WINDOW_FROM_START(WINDOW_SIZE, LIMIT, TASKS, START)

Arguments

WINDOW_SIZE	:	int
LIMIT	:	int
TASKS	:	collection(origin−dvar, duration−dvar)
START	:	dvar

Restrictions

$\texttt{WINDOW\_SIZE} > 0$
$\texttt{LIMIT} \geq 0$
required(TASKS, [origin, duration])
$\texttt{TASKS.duration} \geq 0$

Purpose The sum of the intersections of all the tasks of the TASKS collection with interval $[\texttt{START}, \texttt{START} + \texttt{WINDOW\_SIZE} - 1]$ is less than or equal to LIMIT.

Example

$$\left(9, 6, \left\langle \begin{array}{ll} \texttt{origin} - 10 & \texttt{duration} - 3, \\ \texttt{origin} - 5 & \texttt{duration} - 1, \\ \texttt{origin} - 6 & \texttt{duration} - 2 \end{array} \right\rangle, 5\right)$$

The intersections of tasks $\langle\texttt{id} - 1\ \texttt{origin} - 10\ \texttt{duration} - 3\rangle$, $\langle\texttt{id} - 2\ \texttt{origin} - 5\ \texttt{duration} - 1\rangle$, and $\langle\texttt{id} - 3\ \texttt{origin} - 6\ \texttt{duration} - 2\rangle$ with interval $[\texttt{START}, \texttt{START} + \texttt{WINDOW\_SIZE} - 1] = [5, 5 + 9 - 1] = [5, 13]$ are respectively equal to 3, 1, and 2 (i.e., the three tasks of the TASKS collection are in fact included within interval $[5, 13]$). Consequently, the SLIDING_TIME_WINDOW_FROM_START constraint holds since the sum $3 + 1 + 2$ of these intersections does not exceed the value of its second argument $\texttt{LIMIT} = 6$.

Typical

$\texttt{WINDOW\_SIZE} > 1$
$\texttt{LIMIT} > 0$
$\texttt{LIMIT} < \texttt{WINDOW\_SIZE}$
$|\texttt{TASKS}| > 1$
$\texttt{TASKS.duration} > 0$

Symmetries

- WINDOW_SIZE can be decreased.
- LIMIT can be increased.
- Items of TASKS are permutable.
- TASKS.duration can be decreased to any value ≥ 0.
- One and the same constant can be added to START as well as to the origin attribute of all items of TASKS.

Arg. properties Contractible wrt. TASKS.

Reformulation Similar to the reformulation of SLIDING_TIME_WINDOW.

Used in SLIDING_TIME_WINDOW.

Keywords **characteristic of a constraint:** derived collection.

constraint type: sliding sequence constraint, temporal constraint.

Derived Collection $\texttt{col}(\texttt{S}-\texttt{collection}(\texttt{var}-\texttt{dvar}),[\texttt{item}(\texttt{var}-\texttt{START})])$

Arc input(s)	S TASKS
Arc generator	$PRODUCT \mapsto \texttt{collection}(\texttt{s},\texttt{tasks})$
Arc arity	2
Arc constraint(s)	TRUE
Graph property(ies)	$\mathbf{SUM\_WEIGHT\_ARC}\left(\texttt{max}\left(0, \texttt{min}\left(\begin{array}{l}\texttt{s.var}+\texttt{WINDOW\_SIZE},\\ \texttt{tasks.origin}+\texttt{tasks.duration}\end{array}\right) - \texttt{max}(\texttt{s.var},\texttt{tasks.origin})\right)\right) \leq \texttt{LIMIT}$

Graph model Since we use the TRUE arc constraint the final and the initial graph are identical. The unique source of the final graph corresponds to the interval $[\texttt{START},\texttt{START}+\texttt{WINDOW\_SIZE}-1]$. Each sink of the final graph represents a given task of the TASKS collection. We associate to each arc the value given by the intersection of the task associated with one of the extremities of the arc with the time window $[\texttt{START},\texttt{START}+\texttt{WINDOW\_SIZE}-1]$. Finally, the graph property **SUM_WEIGHT_ARC** sums up all the valuations of the arcs and check that it does not exceed a given limit.

Parts (A) and (B) of Figure 5.732 respectively show the initial and final graph associated with the **Example** slot. To each arc of the final graph we associate the intersection of the corresponding sink task with interval $[\texttt{START},\texttt{START}+\texttt{WINDOW\_SIZE}-1]$. The constraint SLIDING_TIME_WINDOW_FROM_START holds since the sum of the previous intersections does not exceed LIMIT.

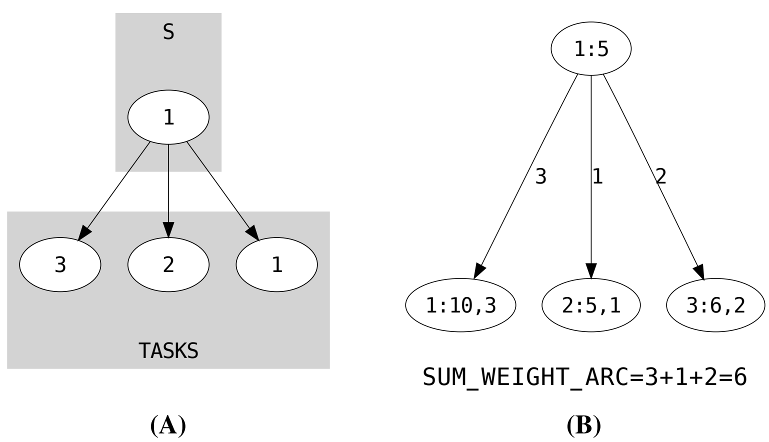

Figure 5.732: Initial and final graph of the SLIDING_TIME_WINDOW_FROM_START constraint

5.361 SLIDING_TIME_WINDOW_SUM

DESCRIPTION LINKS GRAPH

Origin

Derived from SLIDING_TIME_WINDOW.

Constraint

SLIDING_TIME_WINDOW_SUM(WINDOW_SIZE, LIMIT, TASKS)

Arguments

WINDOW_SIZE	:	int
LIMIT	:	int
TASKS	:	collection(origin−dvar, end−dvar, npoint−dvar)

Restrictions

WINDOW_SIZE > 0
LIMIT ≥ 0
required(TASKS, [origin, end, npoint])
TASKS.origin $\leq$ TASKS.end
TASKS.npoint ≥ 0

Purpose

For any time window of size WINDOW_SIZE, the sum of the points of the tasks of the collection TASKS that overlap that time window do not exceed a given limit LIMIT.

Example

$$\left(9, 16, \left\langle \begin{array}{lll} \texttt{origin}-10 & \texttt{end}-13 & \texttt{npoint}-2, \\ \texttt{origin}-5 & \texttt{end}-6 & \texttt{npoint}-3, \\ \texttt{origin}-6 & \texttt{end}-8 & \texttt{npoint}-4, \\ \texttt{origin}-14 & \texttt{end}-16 & \texttt{npoint}-5, \\ \texttt{origin}-2 & \texttt{end}-4 & \texttt{npoint}-6 \end{array} \right\rangle \right)$$

The lower part of Figure 5.733 indicates the different tasks on the time axis. Each task is drawn as a rectangle with its corresponding identifier in the middle. Finally the upper part of Figure 5.733 shows the different time windows and the respective contribution of the tasks in these time windows. A line with two arrows depicts each time window. The two arrows indicate the start and the end of the time window. At the right of each time window we give its occupation. Since this occupation is always less than or equal to the limit 16, the SLIDING_TIME_WINDOW_SUM constraint holds.

Typical

WINDOW_SIZE > 1
LIMIT > 0
LIMIT $<$sum(TASKS.npoint)
$|$TASKS$| > 1$
TASKS.origin $<$ TASKS.end
TASKS.npoint > 0

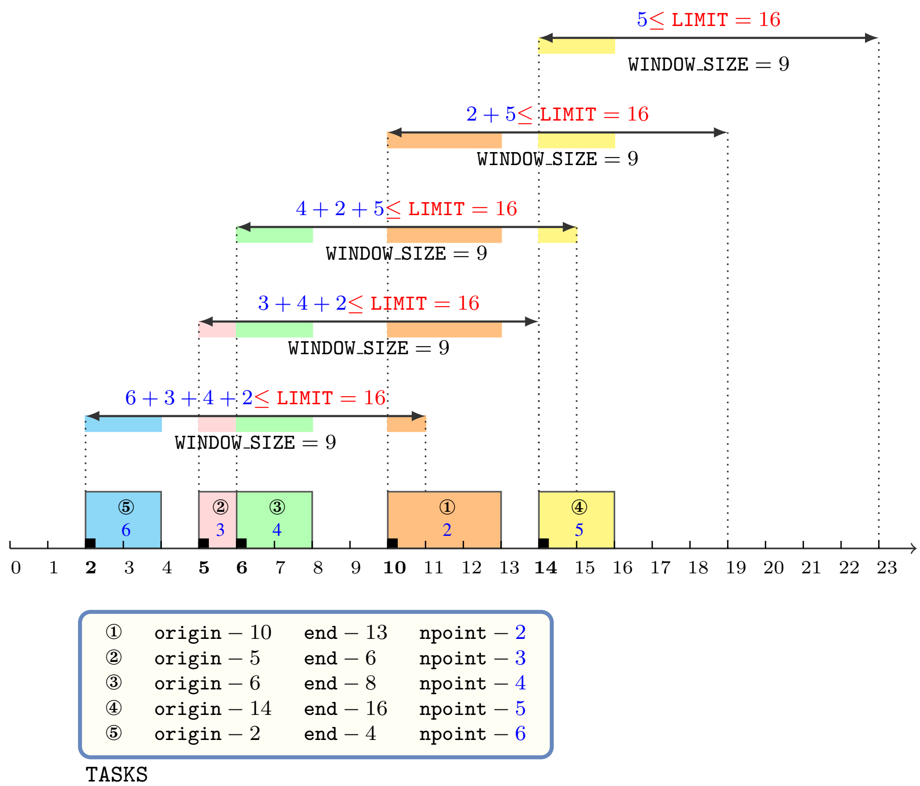

Figure 5.733: Time windows and their uses for the five tasks of the **Example** slot

Symmetries

- WINDOW_SIZE can be decreased.
- LIMIT can be increased.
- Items of TASKS are permutable.
- TASKS.npoint can be decreased to any value ≥ 0.
- One and the same constant can be added to the origin and end attributes of all items of TASKS.

Arg. properties

Contractible wrt. TASKS.

Usage

This constraint may be used for timetabling problems in order to put an upper limit on the cumulated number of points in a shift.

Reformulation

The SLIDING_TIME_WINDOW_SUM constraint can be expressed in term of a set of $|\text{TASKS}|^2$ reified constraints and of $|\text{TASKS}|$ linear inequalities constraints:

1. For each pair of tasks $\text{TASKS}[i], \text{TASKS}[j]$ $(i, j \in [1, |\text{TASKS}|])$ of the TASKS collection we create a variable $Point_{ij}$ which is set to $\text{TASKS}[j].\text{npoint}$ if $\text{TASKS}[j]$ intersects the time window $\mathcal{W}_i$ of size WINDOW_SIZE that starts at instant $\text{TASKS}[i].\text{origin}$, or 0 otherwise:

- If $i = j$ (i.e., $\texttt{TASKS}[i]$ and $\texttt{TASKS}[j]$ coincide):
  - $Point_{ij} = \texttt{TASKS}[i].\texttt{npoint}$.
- If $i \neq j$ and $\overline{\texttt{TASKS}[j].\texttt{end}} < \underline{\texttt{TASKS}[i].\texttt{origin}}$ (i.e., $\texttt{TASKS}[j]$ for sure ends before the time window $\mathcal{W}_i$):
  - $Point_{ij} = 0$.
- If $i \neq j$ and $\underline{\texttt{TASKS}[j].\texttt{origin}} > \overline{\texttt{TASKS}[i].\texttt{origin}} + \texttt{WINDOW\_SIZE} - 1$ (i.e., $\texttt{TASKS}[j]$ for sure starts after the time window $\mathcal{W}_i$):
  - $Point_{ij} = 0$.
- Otherwise (i.e., $\texttt{TASKS}[j]$ can potentially overlap the time window $\mathcal{W}_i$):
  - $Point_{ij} = \min(1, \max(0, \min(\texttt{TASKS}[i].\texttt{origin} + \texttt{WINDOW\_SIZE}, \texttt{TASKS}[j].\texttt{end}) - \max(\texttt{TASKS}[i].\texttt{origin}, \texttt{TASKS}[j].\texttt{origin}))) \cdot \texttt{TASKS}[j].\texttt{npoint}$.

2. For each task $\texttt{TASKS}[i]$ ($i \in [1, |\texttt{TASKS}|]$) we create a linear inequality constraint $Point_{i1} + Point_{i2} + \cdots + Point_{i|\texttt{TASKS}|} \leq \texttt{LIMIT}$.

See also

related: SLIDING_TIME_WINDOW *(sum of the points of intersecting tasks with sliding time window replaced by sum of intersections of tasks with sliding time window)*.

used in graph description: SUM_CTR.

Keywords

characteristic of a constraint: time window, sum.

constraint type: sliding sequence constraint, temporal constraint.

Arc input(s)	TASKS
Arc generator	$SELF \mapsto$ collection(tasks)
Arc arity	1
Arc constraint(s)	tasks.origin $\leq$ tasks.end
Graph property(ies)	$\mathbf{NARC} = \|\mathtt{TASKS}\|$

Arc input(s)	TASKS
Arc generator	$CLIQUE \mapsto$ collection(tasks1, tasks2)
Arc arity	2
Arc constraint(s)	• tasks1.end $\leq$ tasks2.end • tasks2.origin $-$ tasks1.end $<$ WINDOW_SIZE $-$ 1
Sets	$\mathsf{SUCC} \mapsto \left[\begin{array}{l}\mathtt{source},\\ \mathtt{variables}-\mathtt{col}\left(\begin{array}{l}\mathtt{VARIABLES}-\mathtt{collection}(\mathtt{var}-\mathtt{dvar}),\\ [\mathtt{item}(\mathtt{var}-\mathtt{TASKS.npoint})]\end{array}\right)\end{array}\right]$
Constraint(s) on sets	SUM_CTR(variables, $\leq$, LIMIT)

Graph model We generate an arc from a task t_1 to a task t_2 if task t_2 does not end before the end of task t_1 and if task t_2 intersects the time window that starts at the last instant of task t_1. Each set generated by SUCC corresponds to all tasks that intersect in time the time window that starts at instant end $-$ 1, where end is the end of a given task.

Parts (A) and (B) of Figure 5.734 respectively show the initial and final graph associated with the **Example** slot. In the final graph, the successors of a given task t correspond to the set of tasks that both do not end before the end of task t, and intersect the time window that starts at the end $-$ 1 of task t.

Signature Consider the first graph constraint. Since we use the $SELF$ arc generator on the TASKS collection the maximum number of arcs of the final graph is equal to |TASKS|. Therefore we can rewrite $\mathbf{NARC} = |\mathtt{TASKS}|$ to $\mathbf{NARC} \geq |\mathtt{TASKS}|$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

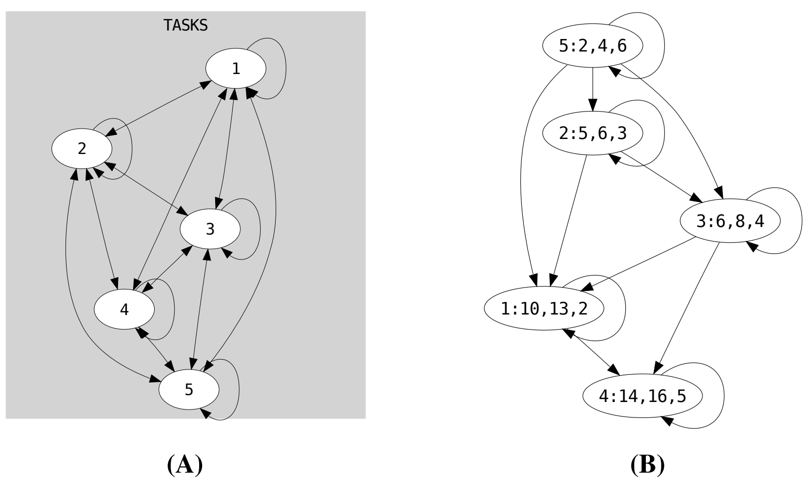

Figure 5.734: Initial and final graph of the SLIDING_TIME_WINDOW_SUM constraint

5.362 SMOOTH

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH AUTOMATON

Origin Derived from CHANGE.

Constraint SMOOTH(NCHANGE, TOLERANCE, VARIABLES)

Arguments

```
NCHANGE    : dvar
TOLERANCE  : int
VARIABLES  : collection(var-dvar)
```

Restrictions

NCHANGE ≥ 0
NCHANGE $<$ |VARIABLES|
TOLERANCE ≥ 0
required(VARIABLES, var)

Purpose NCHANGE is the number of times that $|X - Y| >$ TOLERANCE holds; X and Y correspond to consecutive variables of the collection VARIABLES.

Example $(1, 2, \langle 1, 3, 4, 5, 2\rangle)$

In the example we have one change between values 5 and 2 since the difference in absolute value is greater than the tolerance (i.e., $|5 - 2| > 2$). Consequently the NCHANGE argument is fixed to 1 and the SMOOTH constraint holds.

Typical

TOLERANCE > 0
|VARIABLES| > 3
range(VARIABLES.var) > 1

Typical model nval(VARIABLES.var) > 2

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

- Functional dependency: NCHANGE determined by TOLERANCE and VARIABLES.
- Prefix-contractible wrt. VARIABLES when NCHANGE $= 0$.
- Suffix-contractible wrt. VARIABLES when NCHANGE $= 0$.
- Prefix-contractible wrt. VARIABLES when NCHANGE $=$ |VARIABLES| $- 1$.
- Suffix-contractible wrt. VARIABLES when NCHANGE $=$ |VARIABLES| $- 1$.

Usage This constraint is useful for the following problems:

- Assume that VARIABLES corresponds to the number of people that work on consecutive weeks. One may not normally increase or decrease too drastically the number of people from one week to the next week. With the SMOOTH constraint you can state a limit on the number of drastic changes.
- Assume you have to produce a set of orders, each order having a specific attribute. You want to generate the orders in such a way that there is not a too big difference between the values of the attributes of two consecutive orders. If you cannot achieve this on two given specific orders, this would imply a set-up or a cost. Again, with the SMOOTH constraint, you can control this kind of drastic changes.

Algorithm

A first incomplete algorithm is described in [32]. The sketch of a filtering algorithm for the conjunction of the SMOOTH and the STRETCH constraints based on dynamic programming achieving arc-consistency is mentioned by Lars Hellsten in [219, page 60].

Reformulation

The SMOOTH constraint can be reformulated with the SEQ_BIN constraint [321] that we now introduce. Given N a domain variable, X a sequence of domain variables, and C and B two binary constraints, SEQ_BIN(N, X, C, B) holds if (1) N is equal to the number of C-stretches in the sequence X, and (2) B holds on any pair of consecutive variables in X. A C-stretch is a generalisation of the notion of stretch introduced by G. Pesant [316], where the equality constraint is made explicit by replacing it by a binary constraint C, i.e., a C-stretch is a maximal length subsequence of X for which the binary constraint C is satisfied on consecutive variables. SMOOTH(NCHANGE, VARIABLES, TOLERANCE) can be reformulated as $\texttt{N} = \texttt{N1} - 1 \wedge$ SEQ_BIN($\texttt{N1}, \texttt{X}, |x_i - x_{i+1}| \leq \texttt{TOLERANCE}, \text{true}$), where true is the universal constraint.

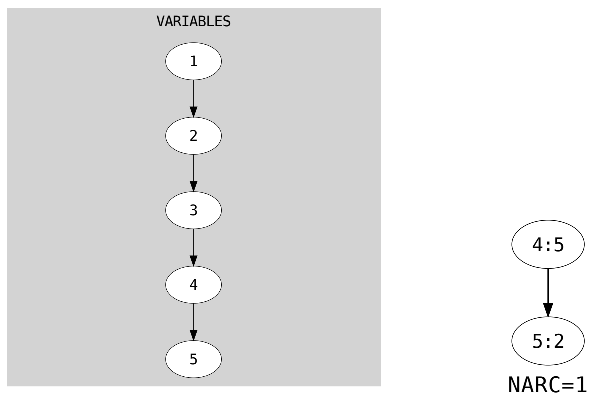
Arc generator	$PATH \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	abs(variables1.var − variables2.var) > TOLERANCE
Graph property(ies)	**NARC**= NCHANGE

Graph model Parts (A) and (B) of Figure 5.735 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the unique arc of the final graph is stressed in bold.



(A) **(B)**

Figure 5.735: Initial and final graph of the SMOOTH constraint

Automaton Figure 5.736 depicts a first automaton that only accepts all the solutions to the SMOOTH constraint. This automaton uses a counter in order to record the number of satisfied constraints of the form $(|\texttt{VAR}_i - \texttt{VAR}_{i+1}|) > \texttt{TOLERANCE}$ already encountered. To each pair of consecutive variables $(\texttt{VAR}_i, \texttt{VAR}_{i+1})$ of the collection VARIABLES corresponds a 0-1 signature variable S_i. The following signature constraint links $\texttt{VAR}_i$, $\texttt{VAR}_{i+1}$ and S_i: $(|\texttt{VAR}_i - \texttt{VAR}_{i+1}|) > \texttt{TOLERANCE} \Leftrightarrow S_i = 1$.

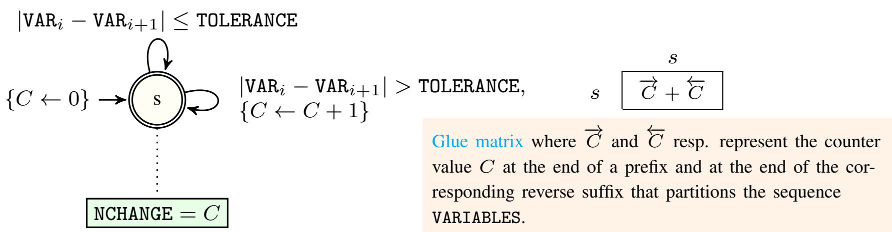


Figure 5.736: Automaton (with one counter) of the SMOOTH constraint and its glue matrix

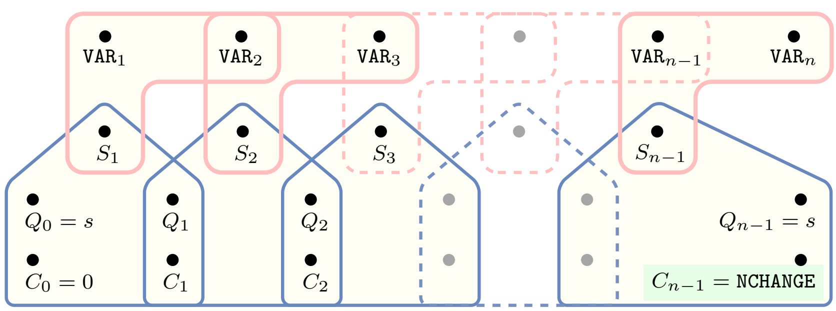

Figure 5.737: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the SMOOTH constraint

Since the reformulation associated with the previous automaton is not Berge-acyclic, we now describe a second counter free automaton that also only accepts all the solutions to the SMOOTH constraint. Without loss of generality, assume that the collection of variables VARIABLES contains at least two variables (i.e., $|\texttt{VARIABLES}| \geq 2$). Let n, min, max, and $\mathcal{D}$ respectively denote the number of variables of the collection VARIABLES, the smallest value that can be assigned to the variables of VARIABLES, the largest value that can be assigned to the variables of VARIABLES, and the union of the domains of the variables of VARIABLES. Clearly, the maximum number of changes (i.e., the number of times the constraint $(|\texttt{VAR}_i - \texttt{VAR}_{i+1}|) > \texttt{TOLERANCE}$ $(1 \leq i < n)$ holds) cannot exceed the quantity $m = \min(n-1, \overline{\texttt{NCHANGE}})$. The $(m+1) \cdot |\mathcal{D}| + 2$ states of the automaton that only accepts all the solutions to the SMOOTH constraint are defined in the following way:

- We have an initial state labelled by s_I.
- We have $m \cdot |\mathcal{D}|$ intermediate states labelled by s_{ij} $(i \in \mathcal{D}, j \in [0, m])$. The first subscript i of state s_{ij} corresponds to the value currently encountered. The second

subscript j denotes the number of already encountered satisfied constraints of the form $(|\texttt{VAR}_k - \texttt{VAR}_{k+1}|) > \texttt{TOLERANCE}$ from the initial state s_I to the state s_{ij}.

- We have an accepting state labelled by s_F.

Four classes of transitions are respectively defined in the following way:

1. There is a transition, labelled by i from the initial state s_I to the state s_{i0}, $(i \in \mathcal{D})$.
2. There is a transition, labelled by j, from every state s_{ij}, $(i \in \mathcal{D}, j \in [0, m])$, to the accepting state s_F.
3. $\forall i \in \mathcal{D}$, $\forall j \in [0, m]$, $\forall k \in \mathcal{D} \cap [\max(min, i - \texttt{TOLERANCE}), \min(max, i + \texttt{TOLERANCE})]$ there is a transition labelled by k from s_{ij} to s_{kj} (i.e., the counter j does not change for values k that are too closed from value i).
4. $\forall i \in \mathcal{D}$, $\forall j \in [0, m-1]$, $\forall k \in \mathcal{D} \setminus [\max(min, i - \texttt{TOLERANCE}), \min(max, i + \texttt{TOLERANCE})]$ there is a transition labelled by k from s_{ij} to s_{kj+1} (i.e., the counter j is incremented by $+1$ for values k that are too far from i).

We have $|\mathcal{D}|$ transitions of type 1, $|\mathcal{D}| \cdot (m+1)$ transitions of type 2, and at least $|\mathcal{D}|^2 \cdot m$ transitions of types 3 and 4. Since the maximum value of m is equal to $n-1$, in the worst case we have at least $|\mathcal{D}|^2 \cdot (n-1)$ transitions. This leads to a worst case time complexity of $O(|\mathcal{D}|^2 \cdot n^2)$ if we use Pesant's algorithm for filtering the REGULAR constraint [317].

Figure 5.738 depicts the corresponding counter free non deterministic automaton associated with the SMOOTH constraint under the hypothesis that (1) all variables of VARIABLES are assigned a value in $\{0, 1, 2, 3\}$, (2) $|\texttt{VARIABLES}|$ is equal to 4, and (3) TOLERANCE is equal to 1.

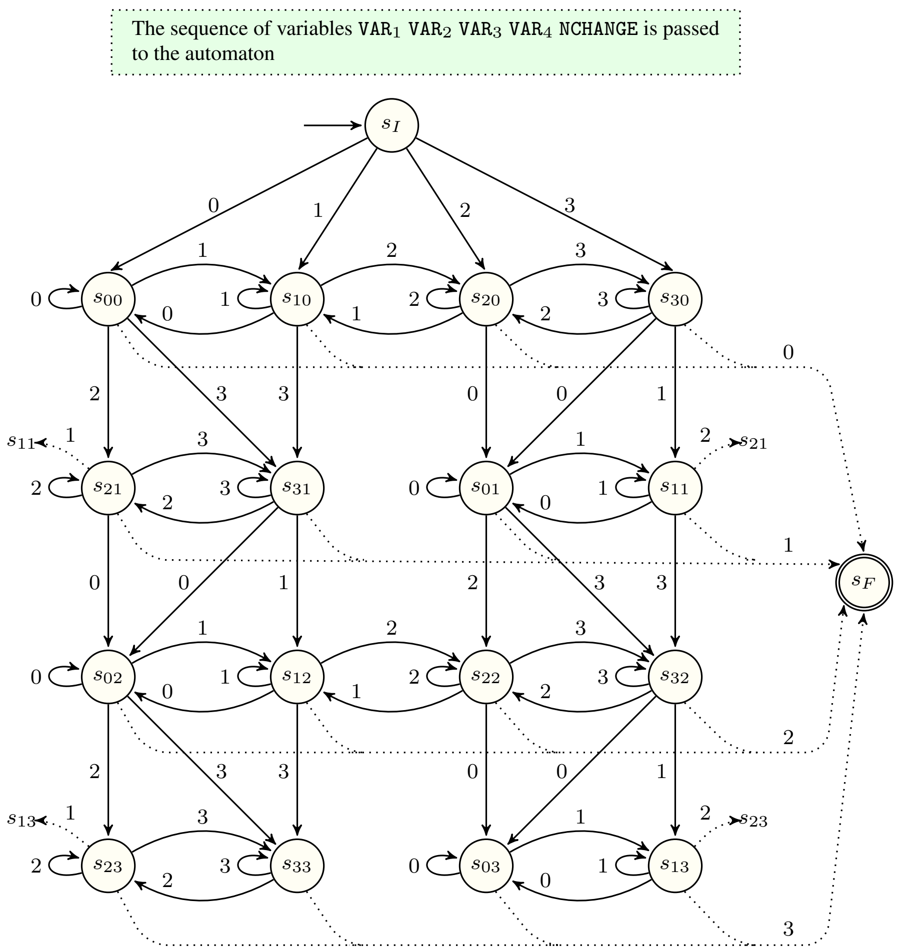

Figure 5.738: Counter free non deterministic automaton of the SMOOTH$(\mathtt{NCHANGE}, 1, \langle \mathtt{VAR}_1, \mathtt{VAR}_2, \mathtt{VAR}_3, \mathtt{VAR}_4\rangle)$ constraint assuming $\mathtt{VAR}_i \in [0, 3]$ $(1 \leq i \leq 3)$, with initial state s_I and accepting state s_F

5.363 SOFT_ALL_EQUAL_MAX_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [158]

Constraint SOFT_ALL_EQUAL_MAX_VAR(N, VARIABLES)

Arguments

N : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\texttt{N} \geq 0$
$\texttt{N} \leq |\texttt{VARIABLES}|$
required(VARIABLES, var)

Purpose

Let M be the number of occurrences of the most often assigned value to the variables of the VARIABLES collection. N is less than or equal to the total number of variables of the VARIABLES collection minus M (i.e., N is less than or equal to the minimum number of variables that need to be reassigned in order to obtain a solution where all variables are assigned a same value).

Example

$(1, \langle 5, 1, 5, 5\rangle)$

Within the collection $\langle 5, 1, 5, 5\rangle$, 3 is the number of occurrences of the most assigned value. Consequently, the SOFT_ALL_EQUAL_MAX_VAR constraint holds since the argument $\texttt{N} = 1$ is less than or equal to the total number of variables 4 minus 3.

Typical

$\texttt{N} > 0$
$\texttt{N} < |\texttt{VARIABLES}|$
$\texttt{N} < |\texttt{VARIABLES}|/10 + 2$
$|\texttt{VARIABLES}| > 1$

Symmetries

- N can be decreased to any value ≥ 0.
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Algorithm [158].

Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**MAX_NSCC**$\leq$ |VARIABLES| − N

Graph model We generate an initial graph with binary *equalities* constraints between each vertex and its successors. The graph property states that N is less than or equal to the difference between the total number of vertices of the initial graph and the number of vertices of the largest strongly connected component of the final graph.

Parts (A) and (B) of Figure 5.739 respectively show the initial and final graph associated with the **Example** slot. Since we use the **MAX_NSCC** graph property we show one of the largest strongly connected components of the final graph.

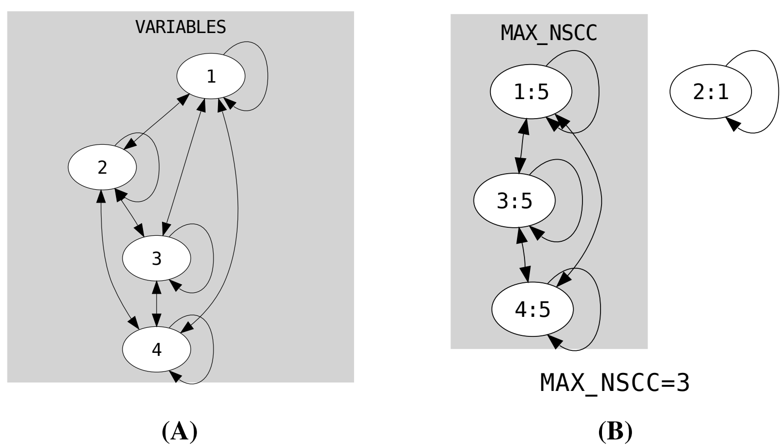

Figure 5.739: Initial and final graph of the SOFT_ALL_EQUAL_MAX_VAR constraint

5.364 SOFT_ALL_EQUAL_MIN_CTR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [216]

Constraint SOFT_ALL_EQUAL_MIN_CTR(N, VARIABLES)

Synonyms SOFT_ALLDIFF_MAX_CTR, SOFT_ALLDIFFERENT_MAX_CTR, SOFT_ALLDISTINCT_MAX_CTR.

Arguments

N	:	int
VARIABLES	:	collection(var−dvar)

Restrictions

$\mathtt{N} \geq 0$
$\mathtt{N} \leq |\mathtt{VARIABLES}| * |\mathtt{VARIABLES}| - |\mathtt{VARIABLES}|$
required(VARIABLES, var)

Purpose Consider the *equality* constraints involving two distinct variables of the collection VARIABLES. Among the previous set of constraints, N is less than or equal to the number of *equality* constraints that hold.

Example $(6, \langle 5, 1, 5, 5\rangle)$

Within the collection $\langle 5, 1, 5, 5\rangle$ six equality constraints holds. Consequently, the SOFT_ALL_EQUAL_CTR constraint holds since the argument $\mathtt{N} = 6$ is less than or equal to the number of equality constraints that hold.

Typical

$\mathtt{N} > 0$
$\mathtt{N} < |\mathtt{VARIABLES}| * |\mathtt{VARIABLES}| - |\mathtt{VARIABLES}|$
$|\mathtt{VARIABLES}| > 1$

Symmetries

- N can be decreased to any value ≥ 0.
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Remark It was shown in [216] that, finding out whether the SOFT_ALL_EQUAL_CTR constraint has a solution or not is NP-hard. This was achieved by reduction from 3-dimensional-matching. Hebrard *et al.* also identify a tractable class when no value occurs in more than two variables of the collection VARIABLES that is equivalent to the vertex matching problem. One year later, [158] shows how to achieve bound-consistency in polynomial time.

See also **common keyword:** SOFT_ALL_EQUAL_MAX_VAR, SOFT_ALL_EQUAL_MIN_VAR, SOFT_ALLDIFFERENT_CTR, SOFT_ALLDIFFERENT_VAR *(soft constraint)*.

hard version: ALL_EQUAL.

implied by: AND, BALANCE, EQUIVALENT, NOR.

related: ATMOST_NVALUE.

Keywords

complexity: 3-dimensional-matching.

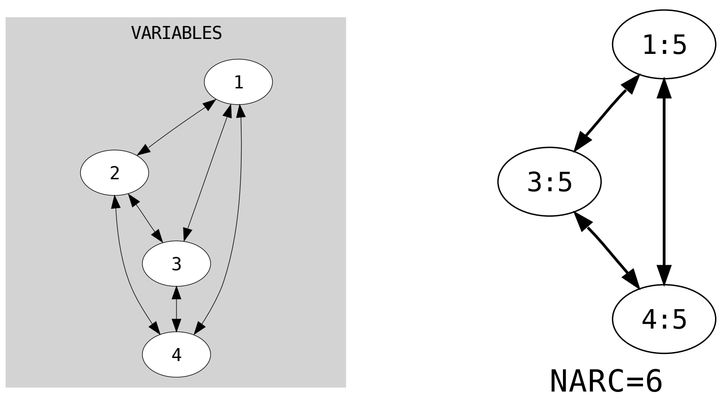
constraint type: soft constraint, value constraint, relaxation, decomposition-based violation measure.

filtering: bound-consistency.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE(\neq) \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NARC** $\geq$ N

Graph model We generate an initial graph with binary *equalities* constraints between each vertex and its successors. We use the arc generator $CLIQUE(\neq)$ in order to avoid considering *equality* constraints between the same variable. The graph property states that N is less than or equal to the number of *equalities* that hold in the final graph.

Parts (A) and (B) of Figure 5.740 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold. Six equality constraints remain in the final graph.



(A) (B)

Figure 5.740: Initial and final graph of the SOFT_ALL_EQUAL_MIN_CTR constraint

5.365 SOFT_ALL_EQUAL_MIN_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [158]

Constraint SOFT_ALL_EQUAL_MIN_VAR(N, VARIABLES)

Arguments

N : dvar
VARIABLES : collection(var−dvar)

Restrictions

$\mathtt{N} \geq 0$
required(VARIABLES, var)

Purpose Let M be the number of occurrences of the most often assigned value to the variables of the VARIABLES collection. N is greater than or equal to the total number of variables of the VARIABLES collection minus M (i.e., N is greater than or equal to the minimum number of variables that need to be reassigned in order to obtain a solution where all variables are assigned a same value).

Example $(1, \langle 5, 1, 5, 5\rangle)$

Within the collection $\langle 5, 1, 5, 5\rangle$, 3 is the number of occurrences of the most assigned value. Consequently, the SOFT_ALL_EQUAL_MIN_VAR constraint holds since the argument $\mathtt{N} = 1$ is greater than or equal to the total number of variables 4 minus 3.

Typical

$\mathtt{N} > 0$
$\mathtt{N} < |\mathtt{VARIABLES}|$
$\mathtt{N} < |\mathtt{VARIABLES}|/10 + 2$
$|\mathtt{VARIABLES}| > 1$

Symmetries

- N can be increased.
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Algorithm Let m denote the total number of potential values that can be assigned to the variables of the VARIABLES collection. In [158], E. Hebrard *et al.* provides an $O(m)$ filtering algorithm achieving arc-consistency on the SOFT_ALL_EQUAL_MIN_VAR constraint. The same paper also provides an algorithm with a lower complexity for achieving range consistency. Both algorithms are based on the following ideas:

- In a first phase, they both compute an *envelope* of the union $\mathcal{D}$ of the domains of the variables of the VARIABLES collection, i.e., an array A that indicates for each potential value v of $\mathcal{D}$, the maximum number of variables that could possibly be assigned value v. Let max_occ denote the maximum value over the entries of array A, and let $\mathcal{V}_{max\_occ}$ denote the set of values which all occur in max_occ variables of the VARIABLES collection. The quantity $|\texttt{VARIABLES}| - max\_occ$ is a lower bound of N.

- In a second phase, depending on the relative ordering between max_occ and the minimum value of $|\texttt{VARIABLES}| - \texttt{N}$, i.e., $|\texttt{VARIABLES}| - \overline{\texttt{N}}$, we have the three following cases:
  1. When $max\_occ < |\texttt{VARIABLES}| - \overline{\texttt{N}}$, the constraint SOFT_ALL_EQUAL_MIN_VAR simply fails since not enough variables of the VARIABLES collection can be assigned the same value.
  2. When $max\_occ = |\texttt{VARIABLES}| - \overline{\texttt{N}}$, the constraint SOFT_ALL_EQUAL_MIN_VAR can be satisfied. In this context, a value v can be removed from the domain of a variable V of the VARIABLES collection if and only if:
     (a) value v does not belong to $\mathcal{V}_{max\_occ}$,
     (b) the domain of variable V contains all values of $\mathcal{V}_{max\_occ}$.

     On the one hand, the first condition can be understand as the fact that value v is not a value that allows the constraint to have at least $|\texttt{VARIABLES}| - \overline{\texttt{N}}$ variables assigned the same value. On the other hand, the second condition can be interpreted as the fact that variable V is absolutely required in order to have at least $|\texttt{VARIABLES}| - \overline{\texttt{N}}$ variables assigned the same value.
  3. When $max\_occ > |\texttt{VARIABLES}| - \overline{\texttt{N}}$, the constraint SOFT_ALL_EQUAL_MIN_VAR can be satisfied, but no value can be pruned.

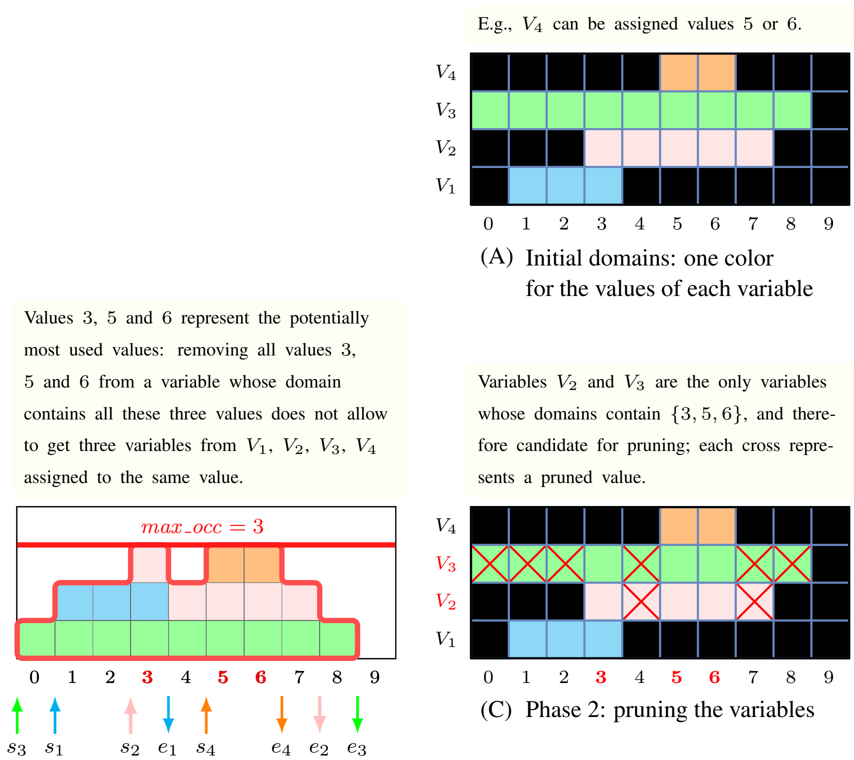
Note that, in the context of range consistency, the first phase of the filtering algorithm can be interpreted as a sweep algorithm were:

- On the one hand, the *sweep status* corresponds to the maximum number of occurrence of variables that can be assigned a given value.
- On the other hand, the *event point series* correspond to the minimum values of the variables of the VARIABLES collection as well as to the maximum values $(+1)$ of the same variables.

Figure 5.741 illustrates the previous filtering algorithm on an example where N is equal to 1, and where we have four variables V_1, V_2, V_3 and V_4 respectively taking their values within intervals $[1,3]$, $[3,7]$, $[0,8]$ and $[5,6]$ (see Part (A) of Figure 5.741, where the values of each variable are assigned a same colour that we retrieve in the other parts of Figure 5.741).

Part (B) of Figure 5.741 illustrates the first phase of the filtering algorithm, namely the computation of the envelope of the domains of variables V_1, V_2, V_3 and V_4. The *start events* s_1, s_2, s_3, s_4 (i.e., the events respectively associated with the minimum value of variables V_1, V_2, V_3, V_4) where the envelope is increased by 1 are represented by the character $\uparrow$. Similarly, the *end events* (i.e., the events e_1, e_2, e_3, e_4 respectively associated with the maximum value $(+1)$ of V_1, V_2, V_3, V_4 are represented by the character $\downarrow$). Since the highest peak of the envelope is equal to 3 we have that max_occ is equal to 3. The values that allow to reach this highest peak are equal to $\mathcal{V}_{max\_occ} = \{3,5,6\}$ (i.e., shown in red in Part (B) of Figure 5.741).

Finally, Part (C) of Figure 5.741 illustrates the second phase of the filtering algorithm. Since $max\_occ = 3$ is equal to $|\texttt{VARIABLES}| - \overline{\texttt{N}} = 4 - 1$ we remove from the variables



(A) Initial domains: one color for the values of each variable

(B) Phase 1: computing the domains envelope (in red) from the sorted start and end events s_3, s_1, s_2, e_1, s_4, e_4, e_2, e_3

(C) Phase 2: pruning the variables

Figure 5.741: Illustration of the two phases filtering algorithm of the SOFT_ALL_EQUAL_MIN_VAR$(1, \langle V_1, V_2, V_3, V_4\rangle)$ constraint with $V_1 \in [1, 3]$, $V_2 \in [3, 7]$, $V_3 \in [0, 8]$ and $V_4 \in [5, 6]$

whose domains contain $\mathcal{V}_{max\_occ} = \{3, 5, 6\}$ (i.e., variables V_2 and V_3) all values not in $\mathcal{V}_{max\_occ} = \{3, 5, 6\}$ (i.e., values 4, 7 for variable V_2 and values 0, 1, 2, 4, 7, 8 for variable V_3).

Arc input(s)	VARIABLES
Arc generator	$CLIQUE \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	$\mathbf{MAX\_NSCC} \geq$ |VARIABLES| − N

Graph model We generate an initial graph with binary *equalities* constraints between each vertex and its successors. The graph property states that N is greater than or equal to the difference between the total number of vertices of the initial graph and the number of vertices of the largest strongly connected component of the final graph.

Parts (A) and (B) of Figure 5.742 respectively show the initial and final graph associated with the **Example** slot. Since we use the $\mathbf{MAX\_NSCC}$ graph property we show one of the largest strongly connected components of the final graph.

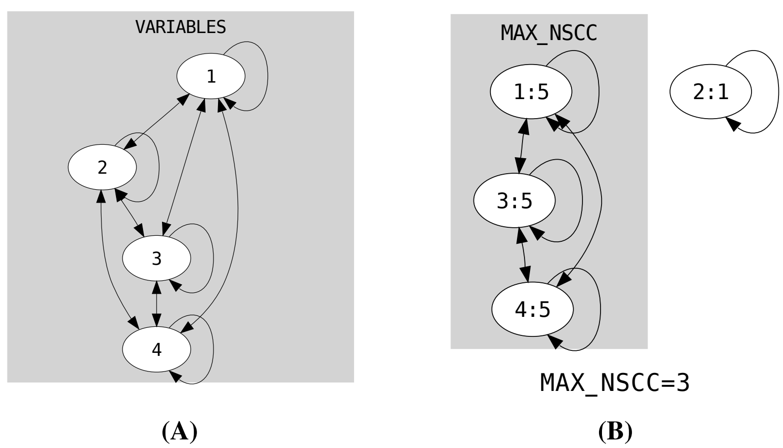

Figure 5.742: Initial and final graph of the SOFT_ALL_EQUAL_MIN_VAR constraint

5.366 SOFT_ALLDIFFERENT_CTR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [325]

Constraint SOFT_ALLDIFFERENT_CTR(C, VARIABLES)

Synonyms SOFT_ALLDIFF_CTR, SOFT_ALLDISTINCT_CTR, SOFT_ALLDIFF_MIN_CTR, SOFT_ALLDIFFERENT_MIN_CTR, SOFT_ALLDISTINCT_MIN_CTR, SOFT_ALL_EQUAL_MAX_CTR.

Arguments

C	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

$\texttt{C} \geq 0$
required(VARIABLES, var)

Purpose Consider the *disequality* constraints involving two distinct variables VARIABLES$[i]$.var and VARIABLES$[j]$.var $(i < j)$ of the collection VARIABLES. Among the previous set of constraints, C is greater than or equal to the number of *disequality* constraints that do not hold.

Example

$(4, \langle 5, 1, 9, 1, 5, 5\rangle)$
$(1, \langle 5, 1, 9, 1, 2, 6\rangle)$
$(0, \langle 5, 1, 9, 0, 2, 6\rangle)$

Within the collection $\langle 5, 1, 9, 1, 5, 5\rangle$ the first and fifth values, the first and sixth values, the second and fourth values, and the fifth and sixth values are identical. Consequently, the argument $\texttt{C} = 4$ is greater than or equal to the number of *disequality* constraints that do not hold (i.e, 4) and the SOFT_ALLDIFFERENT_CTR constraint holds.

Typical

$\texttt{C} > 0$
$\texttt{C} \leq |\texttt{VARIABLES}| * (|\texttt{VARIABLES}| - 1)/2$
$|\texttt{VARIABLES}| > 1$

Symmetries

- C can be increased.
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Contractible wrt. VARIABLES.

Usage A soft ALLDIFFERENT constraint.

Remark

The SOFT_ALLDIFFERENT_CTR constraint is called SOFT_ALLDIFF_MIN_CTR or SOFT_ALL_EQUAL_MAX_CTR in [158].

Algorithm

Since it focus on the soft aspect of the ALLDIFFERENT constraint, the original article [325] that introduces this constraint describes how to evaluate the minimum value of C and how to prune according to the maximum value of C. The corresponding filtering algorithm does not achieve arc-consistency. W.-J. van Hoeve [433] presents a new filtering algorithm that achieves arc-consistency. This algorithm is based on a reformulation into a minimum-cost flow problem.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE(<) \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NARC** $\leq$ C

Graph model We generate an initial graph with binary *equalities* constraints between each vertex and its successors. We use the arc generator $CLIQUE(<)$ in order to avoid counting twice the same *equality* constraint. The graph property states that C is greater than or equal to the number of *equalities* that hold in the final graph.

Parts (A) and (B) of Figure 5.743 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold. Since four equality constraints remain in the final graph the *cost* variable C is greater than or equal to 4.

Figure 5.743: Initial and final graph of the SOFT_ALLDIFFERENT_CTR constraint

5.367 SOFT_ALLDIFFERENT_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [325]

Constraint SOFT_ALLDIFFERENT_VAR(C, VARIABLES)

Synonyms SOFT_ALLDIFF_VAR, SOFT_ALLDISTINCT_VAR, SOFT_ALLDIFF_MIN_VAR, SOFT_ALLDIFFERENT_MIN_VAR, SOFT_ALLDISTINCT_MIN_VAR.

Arguments

C	:	dvar
VARIABLES	:	collection(var−dvar)

Restrictions

$\texttt{C} \geq 0$
required(VARIABLES, var)

Purpose C is greater than or equal to the minimum number of variables of the collection VARIABLES for which the value needs to be changed in order that all variables of VARIABLES take a distinct value.

Example

$(3, \langle 5, 1, 9, 1, 5, 5\rangle)$
$(1, \langle 5, 1, 9, 6, 5, 3\rangle)$
$(0, \langle 8, 1, 9, 6, 5, 3\rangle)$

Within the collection $\langle 5, 1, 9, 1, 5, 5\rangle$ of the first example, 3 and 2 items are respectively fixed to values 5 and 1. Therefore one must change the values of at least $(3 - 1) + (2 - 1) = 3$ items to get back to 6 distinct values. Consequently, the corresponding SOFT_ALLDIFFERENT_VAR constraint holds since its first argument C is greater than or equal to 3.

Typical

$\texttt{C} > 0$
$2 * \texttt{C} \leq |\texttt{VARIABLES}|$
$|\texttt{VARIABLES}| > 1$
SOME_EQUAL(VARIABLES)

Symmetries

- C can be increased.
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

Arg. properties Contractible wrt. VARIABLES.

Usage A soft ALLDIFFERENT constraint.

Remark Since it focus on the soft aspect of the ALLDIFFERENT constraint, the original article [325], which introduce this constraint, describes how to evaluate the minimum value of C and how to prune according to the maximum value of C.

The SOFT_ALLDIFFERENT_VAR constraint is called SOFT_ALLDIFF_MIN_VAR in [158].

Algorithm A first filtering algorithm presented in [325] achieves arc-consistency. A second filtering algorithm also achieving arc-consistency is described in [138, 139].

Reformulation By introducing a variable M that gives the number of distinct values used by variables of the collection VARIABLES, the SOFT_ALLDIFFERENT_VAR(C, VARIABLES) constraint can be expressed as a conjunction of the NVALUE(M, VARIABLES) constraint and of the linear constraint C $\geq$ |VARIABLES| $- M$.

See also **common keyword:** SOFT_ALL_EQUAL_MAX_VAR, SOFT_ALL_EQUAL_MIN_CTR, SOFT_ALL_EQUAL_MIN_VAR, SOFT_ALLDIFFERENT_CTR, WEIGHTED_PARTIAL_ALLDIFF *(soft constraint)*.

hard version: ALLDIFFERENT.

implied by: ALL_MIN_DIST, ALLDIFFERENT_MODULO, SOFT_ALLDIFFERENT_CTR.

related: ATMOST_NVALUE, NVALUE.

Keywords

characteristic of a constraint: all different, disequality.

constraint type: soft constraint, value constraint, relaxation, variable-based violation measure.

filtering: bipartite matching.

final graph structure: strongly connected component, equivalence.

Arc input(s)	VARIABLES
Arc generator	*CLIQUE*$\mapsto$collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NSCC**$\geq$ |VARIABLES| $-$ C

Graph model We generate a clique with binary *equalities* constraints between each pairs of vertices (this include an arc between a vertex and itself) and we state that C is equal to the difference between the total number of variables and the number of strongly connected components.

Parts (A) and (B) of Figure 5.744 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component of the final graph includes all variables that take the same value. Since we have 6 variables and 3 strongly connected components the *cost* variable C is greater than or equal to $6 - 3$.

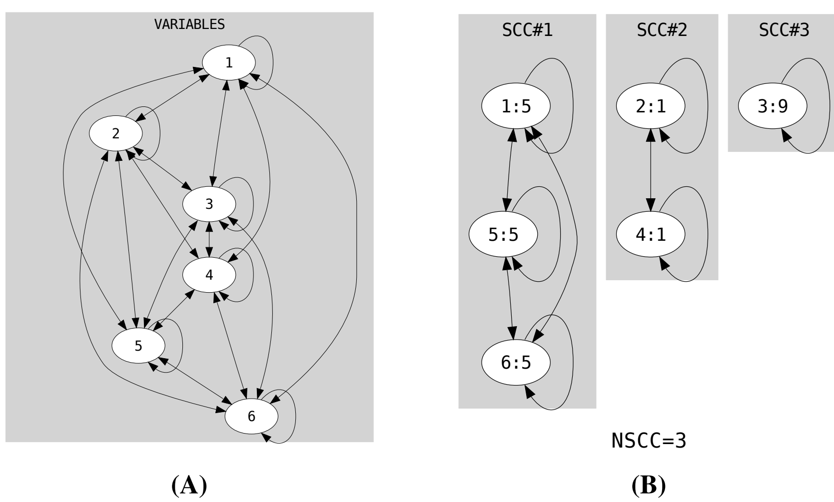

Figure 5.744: Initial and final graph of the SOFT_ALLDIFFERENT_VAR constraint

5.368 SOFT_CUMULATIVE

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Derived from CUMULATIVE

Constraint SOFT_CUMULATIVE(TASKS, LIMIT, INTERMEDIATE_LEVEL, SURFACE_ON_TOP)

Arguments

TASKS	:	collection(origin−dvar, duration−dvar, end−dvar, height−dvar)
LIMIT	:	int
INTERMEDIATE_LEVEL	:	int
SURFACE_ON_TOP	:	dvar

Restrictions

require_at_least(2, TASKS, [origin, duration, end])
required(TASKS, height)
TASKS.duration ≥ 0
TASKS.origin $\leq$ TASKS.end
TASKS.height ≥ 0
LIMIT ≥ 0
INTERMEDIATE_LEVEL ≥ 0
INTERMEDIATE_LEVEL $\leq$ LIMIT
SURFACE_ON_TOP ≥ 0

Purpose

Consider a set $\mathcal{T}$ of n tasks described by the TASKS collection, where $\texttt{origin}_j$, $\texttt{duration}_j$, $\texttt{end}_j$, $\texttt{height}_j$ are shortcuts for TASKS$[j]$.origin, TASKS$[j]$.duration, TASKS$[j]$.end, TASKS$[j]$.height. In addition let α and β respectively denote the earliest possible start over all tasks and the latest possible end over all tasks. The SOFT_CUMULATIVE constraint forces the three following conditions:

1. For each task TASKS$[j]$ $(1 \leq j \leq n)$ of $\mathcal{T}$ we have $\texttt{origin}_j + \texttt{duration}_j = \texttt{end}_j$.
2. At each point in time, the cumulated height of the set of tasks that overlap that point, does not exceed a given limit LIMIT (i.e., $\forall i \in [\alpha, \beta]$: $\sum_{j\in[1,n]|\texttt{origin}_j \leq i < \texttt{end}_j} \texttt{height}_j \leq \texttt{LIMIT}$).
3. The surface of the profile resource utilisation, which is greater than INTERMEDIATE_LEVEL, is equal to SURFACE_ON_TOP (i.e., $\sum_{i\in[\alpha,\beta]} \max(0, (\sum_{j\in[1,n]|\texttt{origin}_j \leq i < \texttt{end}_j} \texttt{height}_j) - \texttt{INTERMEDIATE\_LEVEL}) = \texttt{SURFACE\_ON\_TOP}$).

Example

$$\left(\left\langle\begin{array}{llll} \texttt{origin}-1 & \texttt{duration}-4 & \texttt{end}-5 & \texttt{height}-1, \\ \texttt{origin}-1 & \texttt{duration}-1 & \texttt{end}-2 & \texttt{height}-2, \\ \texttt{origin}-3 & \texttt{duration}-3 & \texttt{end}-6 & \texttt{height}-2 \end{array}\right\rangle, 3, 2, 3\right)$$

Figure 5.745 shows the cumulated profile associated with the example. To each task of the CUMULATIVE constraint corresponds a set of rectangles coloured with the same colour: the sum of the lengths of the rectangles corresponds to the duration of the task, while the height of the rectangles (i.e., all the rectangles associated with a task have the same height) corresponds to the resource consumption of the task. The SOFT_CUMULATIVE constraint holds since:

1. For each task we have that its end is equal to the sum of its origin and its duration.
2. At each point in time we do not have a cumulated resource consumption strictly greater than the upper limit LIMIT $= 3$ enforced by the second argument of the SOFT_CUMULATIVE constraint.
3. The surface of the cumulated profile located on top of the intermediate level INTERMEDIATE_LEVEL $= 2$ is equal to SURFACE_ON_TOP $= 3$.

TASKS

①	o − 1	d − 4	e − 5	h − 1
②	o − 1	d − 1	e − 2	h − 2
③	o − 3	d − 3	e − 6	h − 2

(o for origin, d for duration, e for end, h for height)

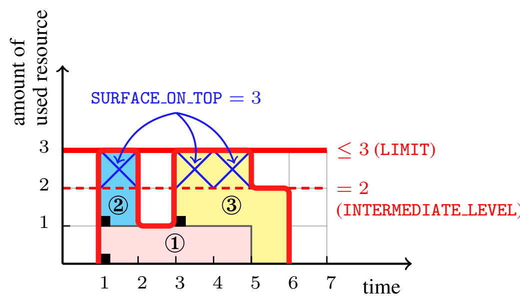

Figure 5.745: Resource consumption profile associated with the three tasks of the **Example** slot, where parts on top of the intermediate level 2 are marked by a cross

Typical

|TASKS| > 1
range(TASKS.origin) > 1
range(TASKS.duration) > 1
range(TASKS.end) > 1
range(TASKS.height) > 1
TASKS.duration > 0
TASKS.height > 0
LIMIT $<$ sum(TASKS.height)
INTERMEDIATE_LEVEL > 0
INTERMEDIATE_LEVEL $<$ LIMIT
SURFACE_ON_TOP > 0

Symmetries

- Items of TASKS are permutable.
- One and the same constant can be added to the origin and end attributes of all items of TASKS.
- LIMIT can be increased.

Remark

The SOFT_CUMULATIVE constraint was initially introduced in **CHIP** [133] as a variant of the CUMULATIVE constraint. An extension of this constraint where one can restrict the surface on top of the intermediate level on different time intervals was first proposed in [322] and was generalised in [127].

See also **hard version:** CUMULATIVE.

Keywords **constraint type:** predefined constraint, soft constraint, scheduling constraint, resource constraint, temporal constraint, relaxation.

5.369 SOFT_SAME_INTERVAL_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from SAME_INTERVAL

Constraint SOFT_SAME_INTERVAL_VAR(C, VARIABLES1, VARIABLES2, SIZE_INTERVAL)

Synonym SOFT_SAME_INTERVAL.

Arguments

C	:	dvar
VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
SIZE_INTERVAL	:	int

Restrictions

$\texttt{C} \geq 0$
$\texttt{C} \leq |\texttt{VARIABLES1}|$
$|\texttt{VARIABLES1}| = |\texttt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
$\texttt{SIZE\_INTERVAL} > 0$

Purpose

Let N_i (respectively M_i) denote the number of variables of the collection VARIABLES1 (respectively VARIABLES2) that take a value in the interval $[\texttt{SIZE\_INTERVAL} \cdot i, \texttt{SIZE\_INTERVAL} \cdot i + \texttt{SIZE\_INTERVAL} - 1$. C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that for all integer i we have $N_i = M_i$.

Example

$(4, \langle 9, 9, 9, 9, 9, 1\rangle, \langle 9, 1, 1, 1, 1, 8\rangle, 3)$

In the example, the fourth argument SIZE_INTERVAL = 3 defines the following family of intervals $[3 \cdot k, 3 \cdot k + 2]$, where k is an integer. Consequently the values of the collections $\langle 9, 9, 9, 9, 9, 1\rangle$ and $\langle 9, 1, 1, 1, 1, 8\rangle$ are respectively located within intervals $[9, 11]$, $[9, 11]$, $[9, 11]$, $[9, 11]$, $[9, 11]$, $[0, 2]$ and intervals $[9, 11]$, $[0, 2]$, $[0, 2]$, $[0, 2]$, $[0, 2]$, $[6, 8]$. Since there is a correspondence between two pairs of intervals we must unset at least $6 - 2$ items (6 is the number of items of the VARIABLES1 and VARIABLES2 collections). Consequently, the SOFT_SAME_INTERVAL_VAR constraint holds since its first argument C is set to $6 - 2$.

Typical

$\texttt{C} > 0$
$|\texttt{VARIABLES1}| > 1$
$\text{range}(\texttt{VARIABLES1.var}) > 1$
$\text{range}(\texttt{VARIABLES2.var}) > 1$
$\texttt{SIZE\_INTERVAL} > 1$
$\texttt{SIZE\_INTERVAL} < \text{range}(\texttt{VARIABLES1.var})$
$\texttt{SIZE\_INTERVAL} < \text{range}(\texttt{VARIABLES2.var})$

Symmetries

- Arguments are permutable w.r.t. permutation (C) (VARIABLES1, VARIABLES2) (SIZE_INTERVAL).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value of VARIABLES1.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.
- An occurrence of a value of VARIABLES2.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Usage A soft SAME_INTERVAL constraint.

Algorithm See algorithm of the SOFT_SAME_VAR constraint.

See also **hard version:** SAME_INTERVAL.

implies: SOFT_USED_BY_INTERVAL_VAR.

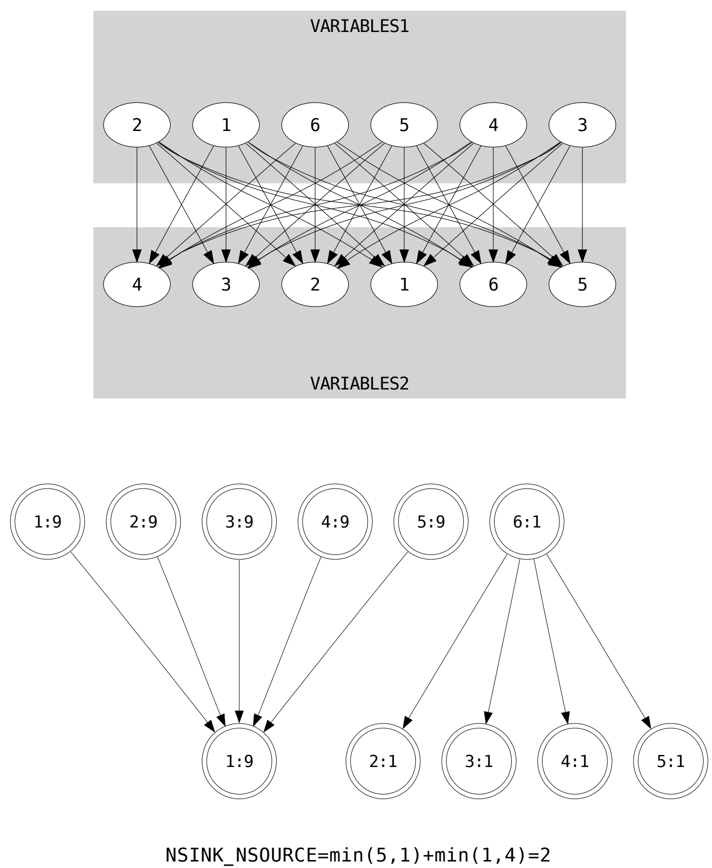
Keywords **constraint arguments:** constraint between two collections of variables.

constraint type: soft constraint, relaxation, variable-based violation measure.

modelling: interval.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var/SIZE_INTERVAL = variables2.var/SIZE_INTERVAL
Graph property(ies)	**NSINK_NSOURCE**= |VARIABLES1| − C

Graph model Parts (A) and (B) of Figure 5.746 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSINK_NSOURCE** graph property, the source and sink vertices of the final graph are stressed with a double circle. The SOFT_SAME_INTERVAL_VAR constraint holds since the cost 4 corresponds to the difference between the number of variables of VARIABLES1 and the sum over the different connected components of the minimum number of sources and sinks.



(A)

(B)

Figure 5.746: Initial and final graph of the SOFT_SAME_INTERVAL_VAR constraint

5.370 SOFT_SAME_MODULO_VAR

DESCRIPTION LINKS GRAPH

Origin

Derived from SAME_MODULO

Constraint

SOFT_SAME_MODULO_VAR(C, VARIABLES1, VARIABLES2, M)

Synonym

SOFT_SAME_MODULO.

Arguments

```
C          : dvar
VARIABLES1 : collection(var-dvar)
VARIABLES2 : collection(var-dvar)
M          : int
```

Restrictions

$\mathtt{C} \geq 0$
$\mathtt{C} \leq |\mathtt{VARIABLES1}|$
$|\mathtt{VARIABLES1}| = |\mathtt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
$\mathtt{M} > 0$

Purpose

For each integer R in $[0, \mathtt{M}-1]$, let $N1_R$ (respectively $N2_R$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that have R as a rest when divided by M. C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that for all R in $[0, \mathtt{M}-1]$ we have $N1_R = N2_R$.

Example

$(4, \langle 9, 9, 9, 9, 9, 1\rangle, \langle 9, 1, 1, 1, 1, 8\rangle, 3)$

In the example, the values of the collections $\langle 9, 9, 9, 9, 9, 1\rangle$ and $\langle 9, 1, 1, 1, 1, 8\rangle$ are respectively associated with the equivalence classes $9 \bmod 3 = 0$, $9 \bmod 3 = 0$, $9 \bmod 3 = 0$, $9 \bmod 3 = 0$, $9 \bmod 3 = 0$, $1 \bmod 3 = 1$ and $9 \bmod 3 = 0$, $1 \bmod 3 = 1$, $1 \bmod 3 = 1$, $1 \bmod 3 = 1$, $1 \bmod 3 = 1$, $8 \bmod 3 = 2$. Since there is a correspondence between two pairs of equivalence classes we must unset at least $6 - 2$ items (6 is the number of items of the VARIABLES1 and VARIABLES2 collections). Consequently, the SOFT_SAME_MODULO_VAR constraint holds since its first argument C is set to $6 - 2$.

Typical

$\mathtt{C} > 0$
$|\mathtt{VARIABLES1}| > 1$
range(VARIABLES1.var) > 1
range(VARIABLES2.var) > 1
$\mathtt{M} > 1$
$\mathtt{M} <$ maxval(VARIABLES1.var)
$\mathtt{M} <$ maxval(VARIABLES2.var)

Symmetries

- Arguments are permutable w.r.t. permutation (C) (VARIABLES1, VARIABLES2) (M).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value u of VARIABLES1.var can be replaced by any other value v such that v is congruent to u modulo M.
- An occurrence of a value u of VARIABLES2.var can be replaced by any other value v such that v is congruent to u modulo M.

Usage A soft SAME_MODULO constraint.

Algorithm See algorithm of the SOFT_SAME_VAR constraint.

See also **hard version:** SAME_MODULO.

implies: SOFT_USED_BY_MODULO_VAR.

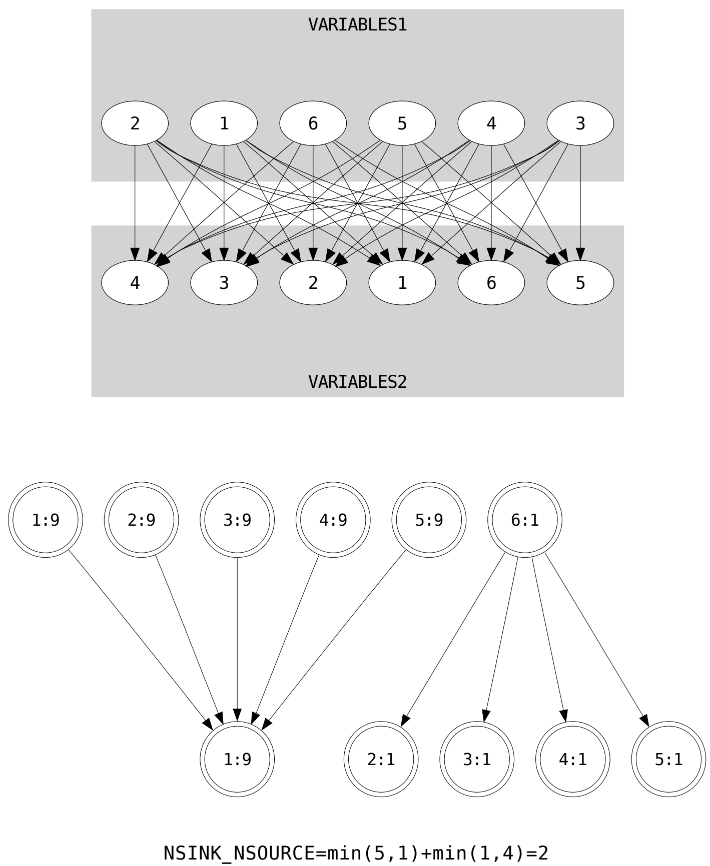
Keywords **characteristic of a constraint:** modulo.

constraint arguments: constraint between two collections of variables.

constraint type: soft constraint, relaxation, variable-based violation measure.

Arc input(s)	`VARIABLES1` `VARIABLES2`
Arc generator	*PRODUCT* $\mapsto$ `collection`(`variables1`, `variables2`)
Arc arity	2
Arc constraint(s)	`variables1.var` mod `M` = `variables2.var` mod `M`
Graph property(ies)	**NSINK_NSOURCE**= |`VARIABLES1`| − `C`

Graph model Parts (A) and (B) of Figure 5.747 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSINK_NSOURCE** graph property, the source and sink vertices of the final graph are stressed with a double circle. The SOFT_SAME_MODULO_VAR constraint holds since the cost 4 corresponds to the difference between the number of variables of `VARIABLES1` and the sum over the different connected components of the minimum number of sources and sinks.



(A)

(B)

Figure 5.747: Initial and final graph of the SOFT_SAME_MODULO_VAR constraint

5.371 SOFT_SAME_PARTITION_VAR

DESCRIPTION LINKS GRAPH

Origin Derived from SAME_PARTITION

Constraint SOFT_SAME_PARTITION_VAR(C, VARIABLES1, VARIABLES2, PARTITIONS)

Synonym SOFT_SAME_PARTITION.

Type

VALUES : collection(val−int)

Arguments

C : dvar
VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)
PARTITIONS : collection(p − VALUES)

Restrictions

C ≥ 0
C $\leq$ |VARIABLES1|
|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)
required(PARTITIONS, p)
|PARTITIONS| ≥ 2
|VALUES| ≥ 1
required(VALUES, val)
distinct(VALUES, val)

Purpose

For each integer i in [1, |PARTITIONS|], let $N1_i$ (respectively $N2_i$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that take their value in the i^{th} partition of the collection PARTITIONS. C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that for all i in [1, |PARTITIONS|] we have $N1_i = N2_i$.

Example

$$\left(\begin{array}{l} 4, \langle 9,9,9,9,9,1\rangle, \\ \langle 9,1,1,1,1,8\rangle, \\ \langle \mathtt{p}-\langle 1,2\rangle, \mathtt{p}-\langle 9\rangle, \mathtt{p}-\langle 7,8\rangle\rangle \end{array}\right)$$

In the example, the values of the collections $\langle 9,9,9,9,9,1\rangle$ and $\langle 9,1,1,1,1,8\rangle$ are respectively associated with the partitions p − $\langle 9\rangle$, p − $\langle 9\rangle$, p − $\langle 9\rangle$, p − $\langle 9\rangle$, p − $\langle 9\rangle$, p − $\langle 1,2\rangle$ and p − $\langle 9\rangle$, p − $\langle 1,2\rangle$, p − $\langle 1,2\rangle$, p − $\langle 1,2\rangle$, p − $\langle 1,2\rangle$, p − $\langle 7,8\rangle$. Since there is a correspondence between two pairs of partitions we must unset at least $6-2$ items (6 is the number of items of the VARIABLES1 and VARIABLES2 collections). Consequently, the SOFT_SAME_PARTITION_VAR constraint holds since its first argument C is set to $6-2$.

Typical

$\mathtt{C} > 0$
$|\mathtt{VARIABLES1}| > 1$
$\mathtt{range}(\mathtt{VARIABLES1.var}) > 1$
$\mathtt{range}(\mathtt{VARIABLES2.var}) > 1$
$|\mathtt{VARIABLES1}| > |\mathtt{PARTITIONS}|$
$|\mathtt{VARIABLES2}| > |\mathtt{PARTITIONS}|$

Symmetries

- Arguments are permutable w.r.t. permutation (C) (VARIABLES1, VARIABLES2) (PARTITIONS).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of VARIABLES1.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.
- An occurrence of a value of VARIABLES2.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Usage A soft SAME_PARTITION constraint.

Algorithm See algorithm of the SOFT_SAME_VAR constraint.

See also **hard version:** SAME_PARTITION.

implies: SOFT_USED_BY_PARTITION_VAR.

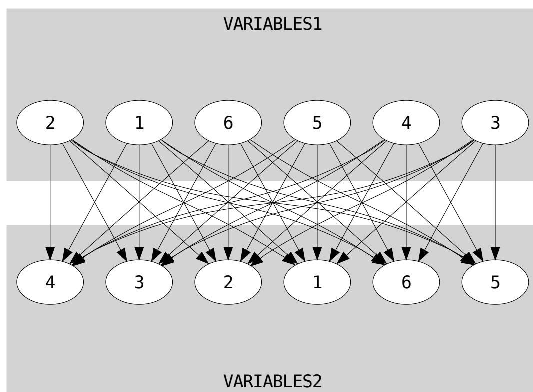
Keywords **characteristic of a constraint:** partition.

constraint arguments: constraint between two collections of variables.

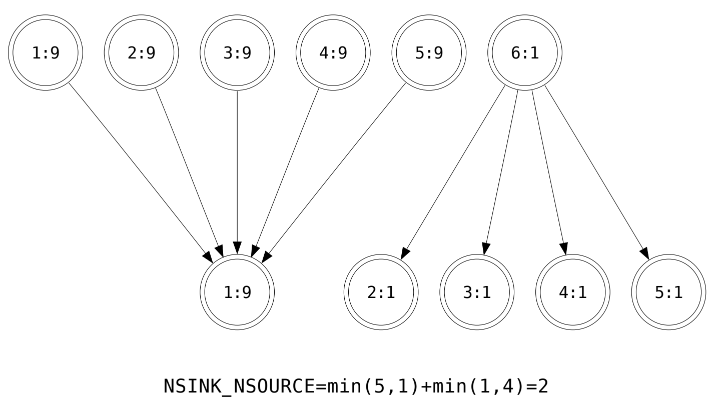
constraint type: soft constraint, relaxation, variable-based violation measure.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	IN_SAME_PARTITION(variables1.var, variables2.var, PARTITIONS)
Graph property(ies)	**NSINK_NSOURCE**$=$ |VARIABLES1| $-$ C

Graph model Parts (A) and (B) of Figure 5.748 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSINK_NSOURCE** graph property, the source and sink vertices of the final graph are stressed with a double circle. The SOFT_SAME_PARTITION_VAR constraint holds since the cost 4 corresponds to the difference between the number of variables of VARIABLES1 and the sum over the different connected components of the minimum number of sources and sinks.



(A)



(B)

Figure 5.748: Initial and final graph of the SOFT_SAME_PARTITION_VAR constraint

5.372 SOFT_SAME_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [434]

Constraint SOFT_SAME_VAR(C, VARIABLES1, VARIABLES2)

Synonym SOFT_SAME.

Arguments

C : dvar
VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)

Restrictions

$\texttt{C} \geq 0$
$\texttt{C} \leq |\texttt{VARIABLES1}|$
$|\texttt{VARIABLES1}| = |\texttt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that the variables of the VARIABLES2 collection correspond to the variables of the VARIABLES1 collection according to a permutation.

Example $(4, \langle 9, 9, 9, 9, 9, 1\rangle, \langle 9, 1, 1, 1, 1, 8\rangle)$

As illustrated by Figure 5.749, there is a correspondence between two pairs of values of the collections $\langle 9, 9, 9, 9, 9, 1\rangle$ and $\langle 9, 1, 1, 1, 1, 8\rangle$. Consequently, we must unset at least $6 - 2$ items (6 is the number of items of the VARIABLES1 and VARIABLES2 collections). The SOFT_SAME_VAR constraint holds since its first argument C is set to $6 - 2$.

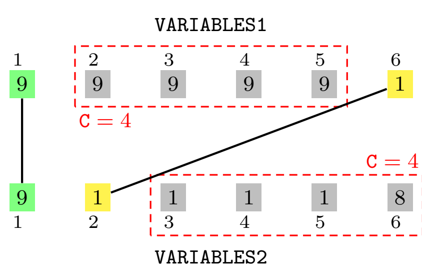


Figure 5.749: Illustration of the partial correspondence between the items of the VARIABLES1 and of the VARIABLES2 collections of the **Example** slot, i.e., $\texttt{C} = 4$ items of the VARIABLES1 or of the VARIABLES2 collections need to be changed in order to have a full correspondence

Typical

$C > 0$
$|VARIABLES1| > 1$
$range(VARIABLES1.var) > 1$
$range(VARIABLES2.var) > 1$

Symmetries

- Arguments are permutable w.r.t. permutation (C) (VARIABLES1, VARIABLES2).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Usage

A soft SAME constraint.

Algorithm

A first filtering algorithm is described in [434, page 80]. A second filtering algorithm is presented in [138, 139].

See also

hard version: SAME.

implies: SOFT_USED_BY_VAR.

Keywords

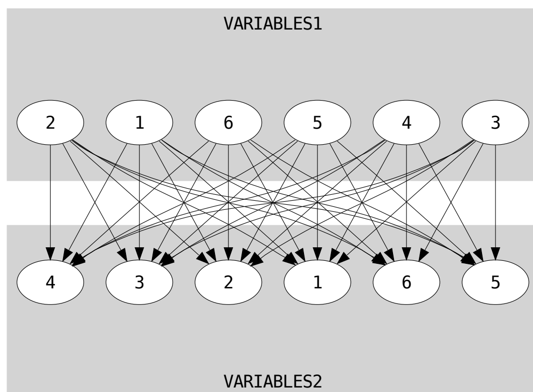
constraint type: soft constraint, relaxation, variable-based violation measure.

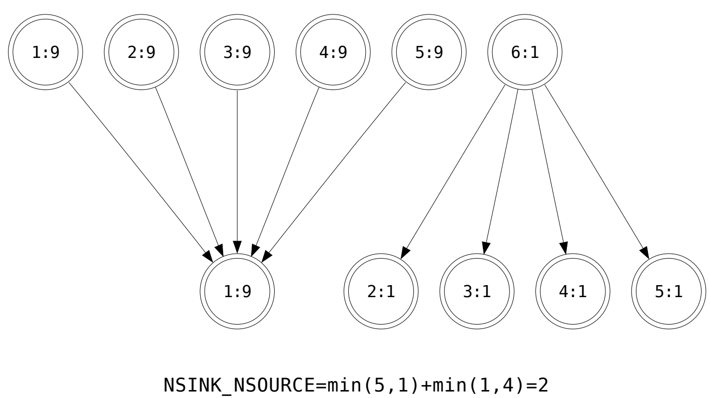
filtering: minimum cost flow, bipartite matching.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	*PRODUCT* ↦ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NSINK_NSOURCE** = |VARIABLES1| − C

Graph model Parts (A) and (B) of Figure 5.750 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSINK_NSOURCE** graph property, the source and sink vertices of the final graph are stressed with a double circle. The SOFT_SAME_VAR constraint holds since the cost 4 corresponds to the difference between the number of variables of VARIABLES1 and the sum over the different connected components of the minimum number of sources and sinks.



(A)



(B)

Figure 5.750: Initial and final graph of the SOFT_SAME_VAR constraint

5.373 SOFT_USED_BY_INTERVAL_VAR

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY_INTERVAL.

Constraint SOFT_USED_BY_INTERVAL_VAR(C, VARIABLES1, VARIABLES2, SIZE_INTERVAL)

Synonym SOFT_USED_BY_INTERVAL.

Arguments

C	:	dvar
VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
SIZE_INTERVAL	:	int

Restrictions

$\texttt{C} \geq 0$
$\texttt{C} \leq |\texttt{VARIABLES2}|$
$|\texttt{VARIABLES1}| \geq |\texttt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
$\texttt{SIZE\_INTERVAL} > 0$

Purpose Let N_i (respectively M_i) denote the number of variables of the collection VARIABLES1 (respectively VARIABLES2) that take a value in the interval $[\texttt{SIZE\_INTERVAL} \cdot i, \texttt{SIZE\_INTERVAL} \cdot i + \texttt{SIZE\_INTERVAL} - 1]$. C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that for all integer i we have $M_i > 0 \Rightarrow N_i \geq M_i$.

Example $(2, \langle 9, 1, 1, 8, 8 \rangle, \langle 9, 9, 9, 1 \rangle, 3)$

In the example, the fourth argument SIZE_INTERVAL $=$ 3 defines the following family of intervals $[3 \cdot k, 3 \cdot k + 2]$, where k is an integer. Consequently the values of the collections $\langle 9, 1, 1, 8, 8 \rangle$ and $\langle 9, 9, 9, 1 \rangle$ are respectively located within intervals $[9, 11]$, $[0, 2]$, $[0, 2]$, $[6, 8]$, $[6, 8]$ and intervals $[9, 11]$, $[9, 11]$, $[9, 11]$, $[0, 2]$. Since there is a correspondence between two pairs of intervals we must unset at least $4 - 2$ items (4 is the number of items of the VARIABLES2 collection). Consequently, the SOFT_USED_BY_INTERVAL_VAR constraint holds since its first argument C is set to $4 - 2$.

Typical

$\texttt{C} > 0$
$|\texttt{VARIABLES1}| > 1$
$|\texttt{VARIABLES2}| > 1$
range(VARIABLES1.var) > 1
range(VARIABLES2.var) > 1
$\texttt{SIZE\_INTERVAL} > 1$
SIZE_INTERVAL $<$range(VARIABLES1.var)
SIZE_INTERVAL $<$range(VARIABLES2.var)

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value of VARIABLES1.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.
- An occurrence of a value of VARIABLES2.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Usage

A soft USED_BY_INTERVAL constraint.

See also

hard version: USED_BY_INTERVAL.

implied by: SOFT_SAME_INTERVAL_VAR.

Keywords

constraint arguments: constraint between two collections of variables.

5.374 SOFT_USED_BY_MODULO_VAR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY_MODULO

Constraint SOFT_USED_BY_MODULO_VAR(C, VARIABLES1, VARIABLES2, M)

Synonym SOFT_USED_BY_MODULO.

Arguments

C	:	dvar
VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
M	:	int

Restrictions

$C \geq 0$
$C \leq |VARIABLES2|$
$|VARIABLES1| \geq |VARIABLES2|$
required(VARIABLES1, var)
required(VARIABLES2, var)
$M > 0$

Purpose

For each integer R in $[0, M-1]$, let $N1_R$ (respectively $N2_R$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that have R as a rest when divided by M. C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that for all R in $[0, M-1]$ we have $N2_R > 0 \Rightarrow N1_R \geq N2_R$.

Example

$(2, \langle 9, 1, 1, 8, 8\rangle, \langle 9, 9, 9, 1\rangle, 3)$

In the example, the values of the collections $\langle 9, 1, 1, 8, 8\rangle$ and $\langle 9, 9, 9, 1\rangle$ are respectively associated with the equivalence classes $9 \bmod 3 = 0$, $1 \bmod 3 = 1$, $1 \bmod 3 = 1$, $8 \bmod 3 = 2$, $8 \bmod 3 = 2$ and $9 \bmod 3 = 0$, $9 \bmod 3 = 0$, $9 \bmod 3 = 0$, $1 \bmod 3 = 1$. Since there is a correspondence between two pairs of equivalence classes we must unset at least $4-2$ items (4 is the number of items of the VARIABLES2 collection). Consequently, the SOFT_USED_BY_MODULO_VAR constraint holds since its first argument C is set to $4-2$.

Typical

$C > 0$
$|VARIABLES1| > 1$
$|VARIABLES2| > 1$
range(VARIABLES1.var) > 1
range(VARIABLES2.var) > 1
$M > 1$
M $<$maxval(VARIABLES1.var)
M $<$maxval(VARIABLES2.var)

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value u of VARIABLES1.var can be replaced by any other value v such that v is congruent to u modulo M.
- An occurrence of a value u of VARIABLES2.var can be replaced by any other value v such that v is congruent to u modulo M.

Usage

A soft USED_BY_MODULO constraint.

5.375 SOFT_USED_BY_PARTITION_VAR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY_PARTITION.

Constraint SOFT_USED_BY_PARTITION_VAR(C, VARIABLES1, VARIABLES2, PARTITIONS)

Synonym SOFT_USED_BY_PARTITION.

Type

VALUES : collection(val−int)

Arguments

C : dvar
VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)
PARTITIONS : collection(p − VALUES)

Restrictions

$\texttt{C} \geq 0$
$\texttt{C} \leq |\texttt{VARIABLES2}|$
$|\texttt{VARIABLES1}| \geq |\texttt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
required(PARTITIONS, p)
$|\texttt{PARTITIONS}| \geq 2$
$|\texttt{VALUES}| \geq 1$
required(VALUES, val)
distinct(VALUES, val)

Purpose

For each integer i in $[1, |\texttt{PARTITIONS}|]$, let $N1_i$ (respectively $N2_i$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that take their values in the i^{th} partition of the collection PARTITIONS. C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that for all i in $[1, |\texttt{PARTITIONS}|]$ we have $N2_i > 0 \Rightarrow N1_i \geq N2_i$.

Example

$$\left(\begin{array}{l} 2, \langle 9,1,1,8,8\rangle, \\ \langle 9,9,9,1\rangle, \\ \langle \texttt{p}-\langle 1,2\rangle, \texttt{p}-\langle 9\rangle, \texttt{p}-\langle 7,8\rangle\rangle \end{array}\right)$$

In the example, the values of the collections $\langle 9,1,1,8,8\rangle$ and $\langle 9,9,9,1\rangle$ are respectively associated with the partitions $\texttt{p}-\langle 9\rangle$, $\texttt{p}-\langle 1,2\rangle$, $\texttt{p}-\langle 1,2\rangle$, $\texttt{p}-\langle 7,8\rangle$, $\texttt{p}-\langle 7,8\rangle$ and $\texttt{p}-\langle 9\rangle$, $\texttt{p}-\langle 9\rangle$, $\texttt{p}-\langle 9\rangle$, $\texttt{p}-\langle 1,2\rangle$. Since there is a correspondence between two pairs of partitions we must unset at least $4-2$ items (4 is the number of items of the VARIABLES2 collection). Consequently, the SOFT_USED_BY_PARTITION_VAR constraint holds since its first argument C is set to $4-2$.

Typical

$\texttt{C} > 0$
$|\texttt{VARIABLES1}| > 1$
$|\texttt{VARIABLES2}| > 1$
$\texttt{range}(\texttt{VARIABLES1.var}) > 1$
$\texttt{range}(\texttt{VARIABLES2.var}) > 1$
$|\texttt{VARIABLES1}| > |\texttt{PARTITIONS}|$
$|\texttt{VARIABLES2}| > |\texttt{PARTITIONS}|$

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of VARIABLES1.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.
- An occurrence of a value of VARIABLES2.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Usage

A soft USED_BY_PARTITION constraint.

See also

hard version: USED_BY_PARTITION.

implied by: SOFT_SAME_PARTITION_VAR.

Keywords

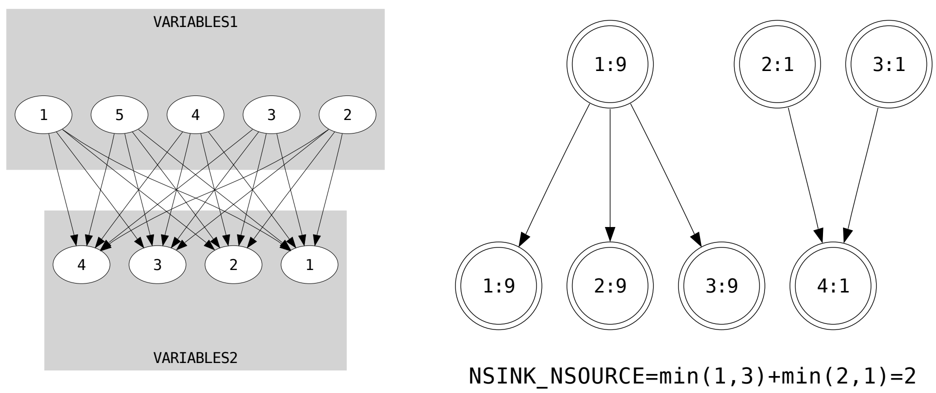
Graph property(ies)	**NSINK_NSOURCE** = |VARIABLES2| − C

Graph model Parts (A) and (B) of Figure 5.753 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSINK_NSOURCE** graph property, the source and sink vertices of the final graph are stressed with a double circle. The SOFT_USED_BY_PARTITION_VAR constraint holds since the cost 2 corresponds to the difference between the number of variables of VARIABLES2 and the sum over the different connected components of the minimum number of sources and sinks.



(A) **(B)**

Figure 5.753: Initial and final graph of the SOFT_USED_BY_PARTITION_VAR constraint

5.376 SOFT_USED_BY_VAR

DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY

Constraint SOFT_USED_BY_VAR(C, VARIABLES1, VARIABLES2)

Synonym SOFT_USED_BY.

Arguments

C	:	dvar
VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)

Restrictions

$\mathtt{C} \geq 0$
$\mathtt{C} \leq |\mathtt{VARIABLES2}|$
$|\mathtt{VARIABLES1}| \geq |\mathtt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose C is the minimum number of values to change in the VARIABLES1 and VARIABLES2 collections so that all the values of the variables of collection VARIABLES2 are used by the variables of collection VARIABLES1.

Example $(2, \langle 9, 1, 1, 8, 8\rangle, \langle 9, 9, 9, 1\rangle)$

As illustrated by Figure 5.754, there is a correspondence between two pairs of values of the collections $\langle 9, 1, 1, 8, 8\rangle$ and $\langle 9, 9, 9, 1\rangle$. Consequently, we must unset at least $4 - 2$ items (4 is the number of items of the VARIABLES2 collection). The SOFT_USED_BY_VAR constraint holds since its first argument C is set to $4 - 2$.

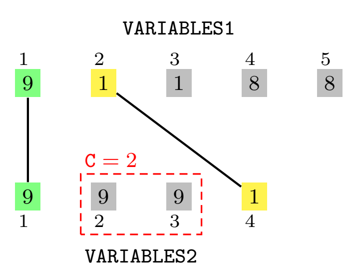


Figure 5.754: Illustration of the partial correspondence between the items of the VARIABLES2 $= \langle 9, 9, 9, 1\rangle$ and of the VARIABLES1 $= \langle 9, 1, 1, 8, 8\rangle$ collections of the **Example** slot, i.e., C $= 2$ items of the VARIABLES2 or of the VARIABLES1 collections need to be changed in order to cover all elements of VARIABLES2

Typical

$\mathtt{C} > 0$
$|\mathtt{VARIABLES1}| > 1$
$|\mathtt{VARIABLES2}| > 1$
$\mathtt{range}(\mathtt{VARIABLES1.var}) > 1$
$\mathtt{range}(\mathtt{VARIABLES2.var}) > 1$

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Usage

A soft USED_BY constraint.

Algorithm

A filtering algorithm achieving arc-consistency is described in [138, 139].

See also

hard version: USED_BY.

implied by: SOFT_SAME_VAR.

Keywords

constraint arguments: constraint between two collections of variables.

constraint type: soft constraint, relaxation, variable-based violation measure.

filtering: bipartite matching.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	*PRODUCT* ↦ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NSINK_NSOURCE** = |VARIABLES2| − C

Graph model Parts (A) and (B) of Figure 5.755 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSINK_NSOURCE** graph property, the source and sink vertices of the final graph are stressed with a double circle. The SOFT_USED_BY_VAR constraint holds since the cost 2 corresponds to the difference between the number of variables of VARIABLES2 and the sum over the different connected components of the minimum number of sources and sinks.

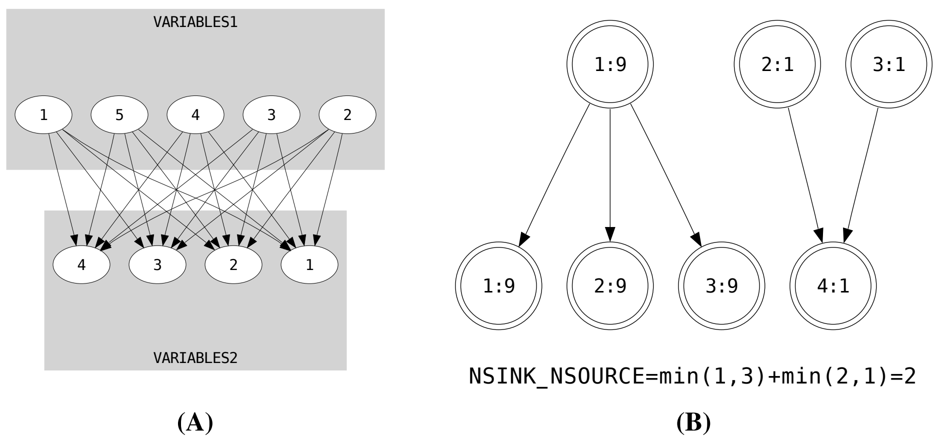

Figure 5.755: Initial and final graph of the SOFT_USED_BY_VAR constraint

5.377 SOME_EQUAL

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from ALLDIFFERENT

Constraint SOME_EQUAL(VARIABLES)

Synonyms SOME_EQ, NOT_ALLDIFFERENT, NOT_ALLDIFF, NOT_ALLDISTINCT, NOT_DISTINCT.

Argument VARIABLES : collection(var−dvar)

Restrictions
required(VARIABLES, var)
$|$VARIABLES$| > 1$

Purpose Enforce at least two variables of the collection VARIABLES to be assigned the same value.

Example $(\langle 1, 4, 1, 6\rangle)$

The SOME_EQUAL constraint holds since the first and the third variables are both assigned the same value 1.

Typical
$|$VARIABLES$| > 2$
nval(VARIABLES.var) > 2

Symmetries
- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.

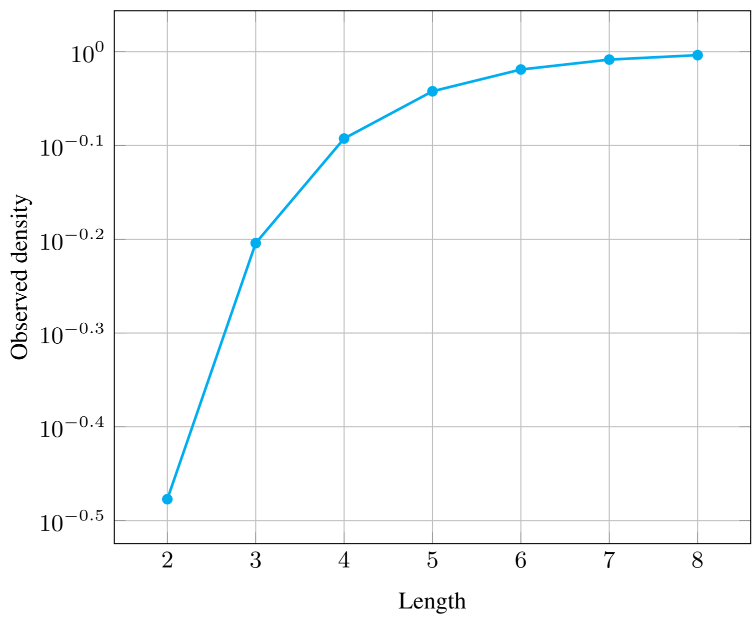
Arg. properties Extensible wrt. VARIABLES.

Counting

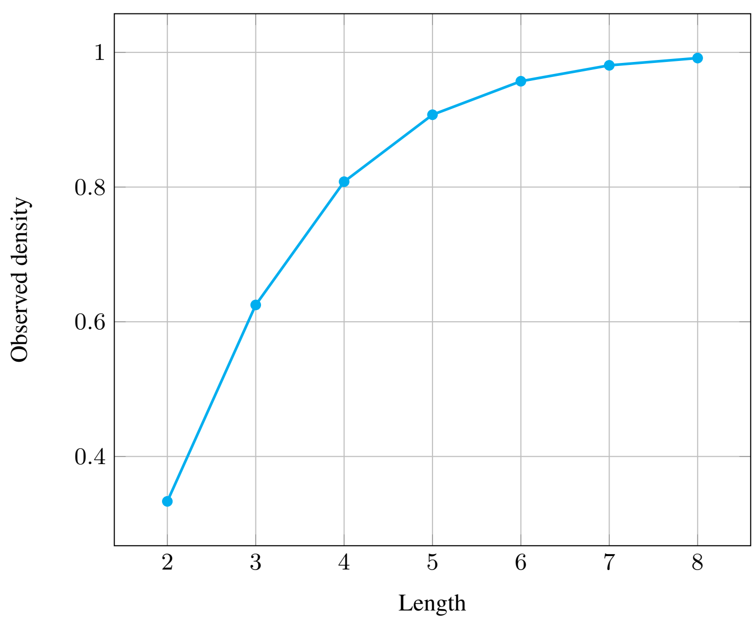
Length (n)	2	3	4	5	6	7	8
Solutions	3	40	505	7056	112609	2056832	42683841

Number of solutions for SOME_EQUAL: domains $0..n$

Solution density for SOME_EQUAL



Solution density for SOME_EQUAL



Used in SOFT_ALLDIFFERENT_VAR.

See also **negation:** ALLDIFFERENT.

Keywords

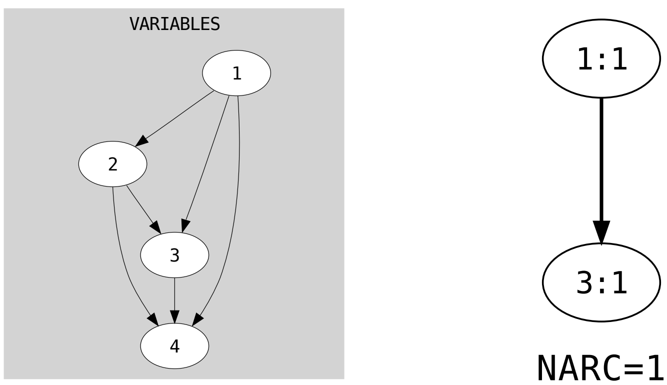
characteristic of a constraint: sort based reformulation.

constraint type: value constraint.

Arc input(s)	VARIABLES
Arc generator	$CLIQUE(<) \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	**NARC** > 0

Graph model We generate a *clique* with an equality constraint between each pair of distinct vertices and state that the number of arcs of the final graph should be strictly greater than 0.

Parts (A) and (B) of Figure 5.756 respectively show the initial and final graph associated with the **Example** slot. The SOME_EQUAL constraint holds since the final graph has at one arc, i.e. two variables are assigned the same value.



(A) **(B)**

Figure 5.756: Initial and final graph of the SOME_EQUAL constraint

5.378 SORT

DESCRIPTION LINKS GRAPH

Origin [308]

Constraint SORT(VARIABLES1, VARIABLES2)

Synonyms SORTEDNESS, SORTED, SORTING.

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)

Restrictions

|VARIABLES1| = |VARIABLES2|
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose First, the variables of the collection VARIABLES2 correspond to a permutation of the variables of VARIABLES1. Second, the variables of VARIABLES2 are sorted in increasing order.

Example $(\langle 1, 9, 1, 5, 2, 1\rangle, \langle 1, 1, 1, 2, 5, 9\rangle)$

The SORT constraint holds since:

- Values 1, 2, 5 and 9 have the same number of occurrences within both collections $\langle 1, 9, 1, 5, 2, 1\rangle$ and $\langle 1, 1, 1, 2, 5, 9\rangle$. Figure 5.757 illustrates this correspondence.
- The items of collection $\langle 1, 1, 1, 2, 5, 9\rangle$ are sorted in increasing order.

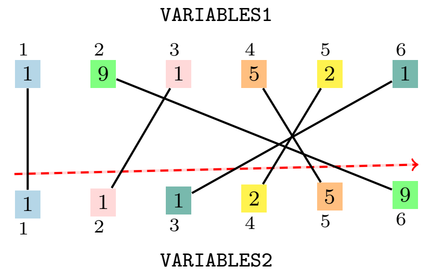


Figure 5.757: Illustration of the correspondence between the items of the VARIABLES1 and of the VARIABLES2 collections of the **Example** slot (note that the items of the VARIABLES2 are sorted in increasing order)

All solutions Figure 5.758 gives all solutions to the following non ground instance of the SORT constraint: $V_1 \in [2,3]$, $V_2 \in [2,3]$, $V_3 \in [1,2]$, $V_4 \in [4,5]$, $V_5 \in [2,4]$, $S_1 \in [2,3]$, $S_2 \in [2,3]$, $S_3 \in [1,3]$, $S_4 \in [4,5]$, $S_5 \in [2,5]$, SORT$(\langle V_1, V_2, V_3, V_4, V_5\rangle, \langle S_1, S_2, S_3, S_4, S_5\rangle)$.

① $(\langle 2,2,2,4,4\rangle, \langle 2,2,2,4,4\rangle)$
② $(\langle 2,2,2,5,4\rangle, \langle 2,2,2,4,5\rangle)$
③ $(\langle 2,3,2,4,4\rangle, \langle 2,2,3,4,4\rangle)$
④ $(\langle 2,3,2,5,4\rangle, \langle 2,2,3,4,5\rangle)$
⑤ $(\langle 3,2,2,4,4\rangle, \langle 2,2,3,4,4\rangle)$
⑥ $(\langle 3,2,2,5,4\rangle, \langle 2,2,3,4,5\rangle)$
⑦ $(\langle 3,3,2,4,4\rangle, \langle 2,3,3,4,4\rangle)$
⑧ $(\langle 3,3,2,5,4\rangle, \langle 2,3,3,4,5\rangle)$

Figure 5.758: All solutions corresponding to the non ground example of the SORT constraint of the **All solutions** slot

Typical

$|$`VARIABLES1`$| > 1$
range(`VARIABLES1.var`) > 1

Symmetries

- Items of `VARIABLES1` are permutable.
- One and the same constant can be added to the `var` attributes of all items of `VARIABLES1` and `VARIABLES2`.

Arg. properties

Functional dependency: `VARIABLES2` determined by `VARIABLES1`.

Usage

The SORT constraint was initially introduced by Older *et al.* [308] for expressing disjunctive constraints in job-shop scheduling problems. It was also used by [22] for expressing disjunctive constraints in an air traffic control application. However the main usage of the SORT constraint, that was not foreseen when the SORT constraint was invented, is its use in many reformulations. Many constraints involving one or several collections of variables *become much simpler to express when the variables of these collections are sorted*. In addition these reformulations typically have a size that is linear in the number of variables of the original constraint. This justifies why the SORT constraint is considered to be a core constraint. As illustrative examples of these types of reformulations we successively consider the ALLDIFFERENT and the SAME constraints:

- The ALLDIFFERENT$(\langle v_1, v_2, \ldots, v_n\rangle)$ constraint can be reformulated as the conjunction SORT$(\langle v_1, v_2, \ldots, v_n\rangle, \langle w_1, w_2, \ldots, w_n\rangle)$ $\wedge$ STRICTLY_INCREASING$(\langle w_1, w_2, \ldots, w_n\rangle)$.
- The SAME$(\langle u_1, u_2, \ldots, u_n\rangle, \langle v_1, v_2, \ldots, v_n\rangle)$ constraint can be reformulated as the conjunction SORT$(\langle u_1, u_2, \ldots, u_n\rangle, \langle w_1, w_2, \ldots, w_n\rangle)$ $\wedge$ SORT$(\langle v_1, v_2, \ldots, v_n\rangle, \langle w_1, w_2, \ldots, w_n\rangle)$.

Remark

A variant of this constraint called SORT_PERMUTATION was introduced in [461]. In this variant an additional list of domain variables represents the permutation that allows one to go from `VARIABLES1` to `VARIABLES2`.

implies: LEX_GREATEREQ, SAME.

uses in its reformulation: ALLDIFFERENT, SAME.

Keywords **application area:** air traffic management.

characteristic of a constraint: core, sort.

combinatorial object: permutation.

constraint arguments: constraint between two collections of variables, pure functional dependency.

filtering: bound-consistency.

modelling: functional dependency.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	• for all connected components: **NSOURCE**=**NSINK** • **NSOURCE**= |VARIABLES1| • **NSINK**= |VARIABLES2|

Arc input(s)	VARIABLES2
Arc generator	$PATH \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var $\leq$ variables2.var
Graph property(ies)	**NARC**= |VARIABLES2| $-$ 1

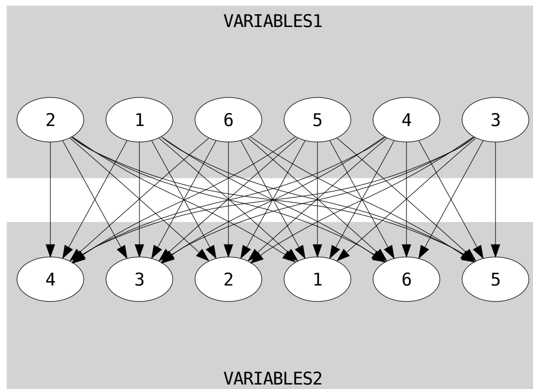
Graph model Parts (A) and (B) of Figure 5.759 respectively show the initial and final graph associated with the first graph constraint of the **Example** slot. Since it uses the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of this final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. The SORT constraint holds since:

- Each connected component of the final graph of the first graph constraint has the same number of sources and of sinks.
- The number of sources of the final graph of the first graph constraint is equal to |VARIABLES1|.
- The number of sinks of the final graph of the first graph constraint is equal to |VARIABLES2|.
- Finally the second graph constraint holds also since its corresponding final graph contains exactly |VARIABLES1 $-$ 1| arcs: all the inequalities constraints between consecutive variables of VARIABLES2 holds.

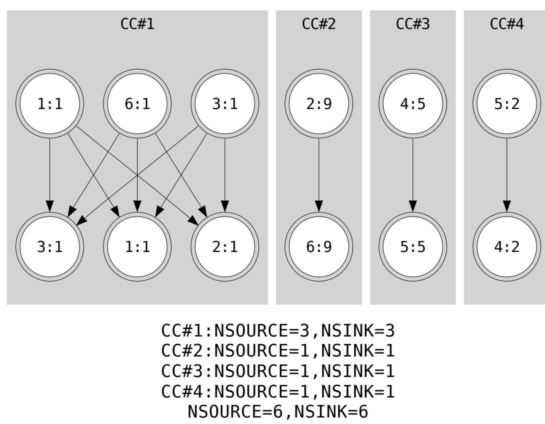
Signature Consider the first graph constraint. Since the initial graph contains only sources and sinks, and since isolated vertices are eliminated from the final graph, we make the following observations:

- Sources of the initial graph cannot become sinks of the final graph,
- Sinks of the initial graph cannot become sources of the final graph.

From the previous observations and since we use the $PRODUCT$ arc generator on the collections VARIABLES1 and VARIABLES2, we have that the maximum number of sources and sinks of the final graph is respectively equal to |VARIABLES1| and |VARIABLES2|. Therefore we can rewrite **NSOURCE** = |VARIABLES1| to **NSOURCE** $\geq$ |VARIABLES1| and simplify $\underline{\overline{\mathbf{NSOURCE}}}$ to $\overline{\mathbf{NSOURCE}}$. In a similar way, we can rewrite **NSINK** = |VARIABLES2| to **NSINK** $\geq$ |VARIABLES2| and simplify $\underline{\overline{\mathbf{NSINK}}}$ to $\overline{\mathbf{NSINK}}$.



(A)



(B)

Figure 5.759: Initial and final graph of the SORT constraint

Consider now the second graph constraint. Since we use the $PATH$ arc generator with an arity of 2 on the VARIABLES2 collection, the maximum number of arcs of the final graph is equal to $|\mathtt{VARIABLES2}| - 1$. Therefore we can rewrite the graph property $\mathbf{NARC} = |\mathtt{VARIABLES2}| - 1$ to $\mathbf{NARC} \geq |\mathtt{VARIABLES2}| - 1$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

Quiz

EXERCISE 1 (checking whether a ground instance holds or not)[a]

A. Does the constraint SORT$(\langle 1, 0, 0, 1\rangle, \langle 0, 0, 1\rangle)$ hold?

B. Does the constraint SORT$(\langle 3, 5, 3, 1\rangle, \langle 1, 3, 5\rangle)$ hold?

C. Does the constraint SORT$(\langle 2, 4, 2, 2, 4\rangle, \langle 2, 2, 2, 4, 4\rangle)$ hold?

D. Does the constraint SORT$(\langle 2, 4, 2, 2, 4\rangle, \langle 4, 4, 2, 2, 2\rangle)$ hold?

[a]Hint: go back to the definition of SORT.

EXERCISE 2 (finding all solutions)[a]

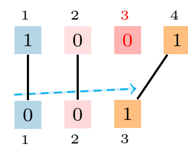
Give all the solutions to the constraint:

$$\left\{\begin{array}{lllll} X_1 \in [2,4], & X_2 \in [2,3], & X_3 \in [0,5], & X_4 \in [6,8], & X_5 \in [3,6], \\ Y_1 \in [3,4], & Y_2 \in [2,3], & Y_3 \in [0,5], & Y_4 \in [6,8], & Y_5 \in [3,6], \\ & & & & \\ \multicolumn{5}{l}{\textsc{sort}\left(\begin{array}{lllll} \langle X_1, & X_2, & X_3, & X_4, & X_5\rangle, \\ \langle Y_1, & Y_2, & Y_3, & Y_4, & Y_5\rangle \end{array}\right).} \end{array}\right.$$

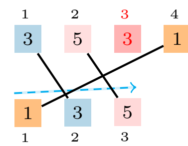
[a]Hint: first filter the bounds of the variables of the second argument with respect to the chain of precedences; second, since the second argument can be computed from the first one, focus on the variables of the first argument and enumerate solutions in lexicographic order.

SOLUTION TO EXERCISE 1

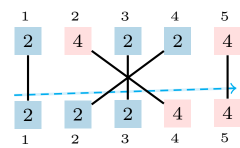
A. *No, since* $\langle 1, 0, 0, 1\rangle$ *and* $\langle 0, 0, 1\rangle$ *do not have the same number of elements.*



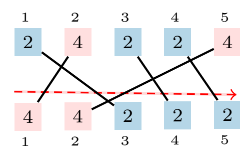
B. *No, since* $\langle 3, 5, 3, 1\rangle$ *and* $\langle 1, 3, 5\rangle$ *do not have the same number of elements.*



C. *Yes, since* $\langle 2, 2, 2, 4, 4\rangle$ *is a permutation of* $\langle 2, 4, 2, 2, 4\rangle$ *and since the elements* $2, 2, 2, 4, 4$ *are sorted in non-decreasing order.*



D. *No, since the elements of* $\langle 4, 4, 2, 2, 2\rangle$ *are not sorted in non-decreasing order.*



SOLUTION TO EXERCISE 2

the four solutions

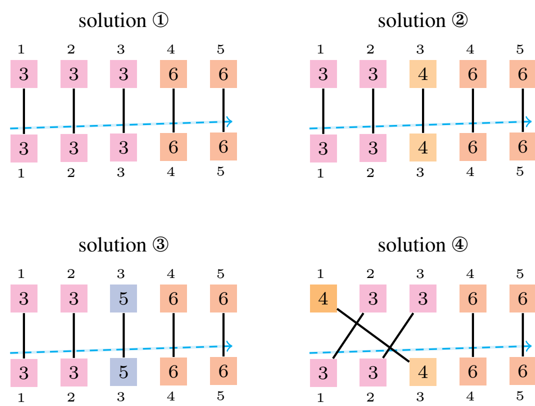
$\langle X_1, X_2, X_3, X_4, X_5 \rangle, \langle Y_1, Y_2, Y_3, Y_4, Y_5 \rangle$

① $(\langle 3, 3, 3, 6, 6 \rangle, \ \langle 3, 3, 3, 6, 6 \rangle)$

② $(\langle 3, 3, 4, 6, 6 \rangle, \ \langle 3, 3, 4, 6, 6 \rangle)$

③ $(\langle 3, 3, 5, 6, 6 \rangle, \ \langle 3, 3, 5, 6, 6 \rangle)$

④ $(\langle 4, 3, 3, 6, 6 \rangle, \ \langle 3, 3, 4, 6, 6 \rangle)$



5.379 SORT_PERMUTATION

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [460]

Constraint SORT_PERMUTATION(FROM, PERMUTATION, TO)

Usual name SORT

Synonyms EXTENDED_SORTEDNESS, SORTEDNESS, SORTED, SORTING.

Arguments

FROM	:	collection(var−dvar)
PERMUTATION	:	collection(var−dvar)
TO	:	collection(var−dvar)

Restrictions

$|\text{PERMUTATION}| = |\text{FROM}|$
$|\text{PERMUTATION}| = |\text{TO}|$
PERMUTATION.var ≥ 1
PERMUTATION.var $\leq |\text{PERMUTATION}|$
ALLDIFFERENT(PERMUTATION)
required(FROM, var)
required(PERMUTATION, var)
required(TO, var)

Purpose The variables of collection FROM correspond to the variables of collection TO according to the permutation PERMUTATION (i.e., FROM$[i]$.var $=$ TO[PERMUTATION$[i]$.var].var). The variables of collection TO are also sorted in increasing order.

Example $(\langle 1,9,1,5,2,1\rangle, \langle 1,6,3,5,4,2\rangle, \langle 1,1,1,2,5,9\rangle)$

The SORT_PERMUTATION constraint holds since:

- – The first item FROM[1].var $=$ 1 of collection FROM corresponds to the PERMUTATION[1].var $= 1^{th}$ item of collection TO.
  – The second item FROM[2].var $=$ 9 of collection FROM corresponds to the PERMUTATION[2].var $= 6^{th}$ item of collection TO.
  – The third item FROM[3].var $=$ 1 of collection FROM corresponds to the PERMUTATION[3].var $= 3^{th}$ item of collection TO.
  – The fourth item FROM[4].var $=$ 5 of collection FROM corresponds to the PERMUTATION[4].var $= 5^{th}$ item of collection TO.
  – The fifth item FROM[5].var $=$ 2 of collection FROM corresponds to the PERMUTATION[5].var $= 4^{th}$ item of collection TO.
  – The sixth item FROM[6].var $=$ 1 of collection FROM corresponds to the PERMUTATION[6].var $= 2^{th}$ item of collection TO.
- The items of collection TO $= \langle 1,1,1,2,5,9\rangle$ are sorted in increasing order.

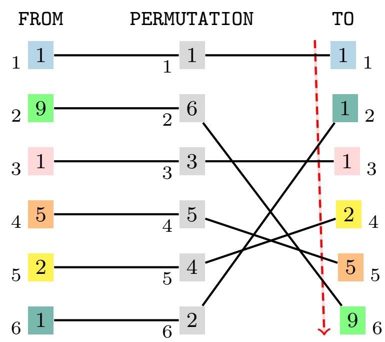


Figure 5.760: Illustration of the correspondence between the items of the FROM and the TO collections according to the permutation defined by the items of the PERMUTATION collection of the **Example** slot (note that the items of the TO collection are sorted in increasing order)

Typical

$|\texttt{FROM}| > 1$
$\texttt{range}(\texttt{FROM.var}) > 1$
LEX_DIFFERENT(FROM, TO)

Symmetry

One and the same constant can be added to the var attributes of all items of FROM and TO.

Arg. properties

Functional dependency: TO determined by FROM.

Remark

Observe that the argument PERMUTATION of the SORT_PERMUTATION constraint is not completely determined by FROM and TO when the items of the collection FROM are not all distinct. In other words this means that even though all items of the FROM and TO are completely fixed, *the permutation will not be completely determined* when some items of FROM are assigned the same value.

The SORT_PERMUTATION constraint is referenced under the name SORTING in **SICStus Prolog**.

Algorithm

[461].

Reformulation

Let n denote the number of variables in the collection FROM. The SORT_PERMUTATION constraint can be reformulated as a conjunction of the form:

ELEMENT(PERMUTATION[1], FROM, TO[1]),
ELEMENT(PERMUTATION[2], FROM, TO[2]),
...
ELEMENT(PERMUTATION[n], FROM, TO[n]),
ALLDIFFERENT(PERMUTATION),
INCREASING(TO).

To enhance the previous model, the following necessary condition was proposed by P. Schaus. $\forall i \in [1, n] : \sum_{j=1}^{j=n} (\texttt{FROM}[j] < \texttt{TO}[i]) \leq i-1$ (i.e., at most $i-1$ variables of the collection FROM are assigned a value strictly less than TO[i]). Similarly, we have that $\forall i \in [1, n] : \sum_{j=1}^{j=n} (\mathtt{FROM}[j] > \mathtt{TO}[i]) \geq n - i$ (i.e., at most $n - i$ variables of the collection FROM are assigned a value are strictly greater than TO$[i]$).

Systems SORTED in **Gecode**, SORTING in **SICStus**.

See also **common keyword:** ORDER *(sort, permutation)*.

implies: CORRESPONDENCE.

specialisation: SORT *(*PERMUTATION *parameter removed)*.

used in reformulation: ALLDIFFERENT, ELEMENT, INCREASING.

Keywords **characteristic of a constraint:** sort, derived collection.

combinatorial object: permutation.

constraint arguments: constraint between three collections of variables.

modelling: functional dependency.

Derived Collection

$$\texttt{col}\left(\begin{array}{l}\texttt{FROM\_PERMUTATION}-\texttt{collection}(\texttt{var}-\texttt{dvar},\texttt{ind}-\texttt{dvar}),\\ [\texttt{item}(\texttt{var}-\texttt{FROM.var},\texttt{ind}-\texttt{PERMUTATION.var})]\end{array}\right)$$

Arc input(s) FROM_PERMUTATION TO

Arc generator $PRODUCT \mapsto \texttt{collection}(\texttt{from\_permutation},\texttt{to})$

Arc arity 2

Arc constraint(s)
- $\texttt{from\_permutation.var} = \texttt{to.var}$
- $\texttt{from\_permutation.ind} = \texttt{to.key}$

Graph property(ies) $\mathbf{NARC} = |\texttt{PERMUTATION}|$

Arc input(s) TO

Arc generator $PATH \mapsto \texttt{collection}(\texttt{to1},\texttt{to2})$

Arc arity 2

Arc constraint(s) $\texttt{to1.var} \leq \texttt{to2.var}$

Graph property(ies) $\mathbf{NARC} = |\texttt{TO}| - 1$

Graph model Parts (A) and (B) of Figure 5.761 respectively show the initial and final graph associated with the first graph constraint of the **Example** slot. In both graphs the source vertices correspond to the items of the derived collection FROM_PERMUTATION, while the sink vertices correspond to the items of the TO collection. Since the first graph constraint uses the $\mathbf{NARC}$ graph property, the arcs of its final graph are stressed in bold. The SORT_PERMUTATION constraint holds since:

- The first graph constraint holds since its final graph contains exactly PERMUTATION arcs.
- Finally the second graph constraint holds also since its corresponding final graph contains exactly $|\texttt{PERMUTATION} - 1|$ arcs: all the inequalities constraints between consecutive variables of TO holds.

Signature Consider the first graph constraint where we use the $PRODUCT$ arc generator. Since all the key attributes of the TO collection are distinct, and because of the second condition $\texttt{from\_permutation.ind} = \texttt{to.key}$ of the arc constraint, each vertex of the final graph has at most one successor. Therefore the maximum number of arcs of the final graph is equal to $|\texttt{PERMUTATION}|$. So we can rewrite the graph property $\mathbf{NARC} = |\texttt{PERMUTATION}|$ to $\mathbf{NARC} \geq |\texttt{PERMUTATION}|$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

Consider now the second graph constraint. Since we use the $PATH$ arc generator with an arity of 2 on the TO collection, the maximum number of arcs of the corresponding final graph is equal to $|\texttt{TO}| - 1$. Therefore we can rewrite $\mathbf{NARC} = |\texttt{TO}| - 1$ to $\mathbf{NARC} \geq |\texttt{TO}| - 1$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.380 STABLE_COMPATIBILITY

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin P. Flener, [49]

Constraint STABLE_COMPATIBILITY(NODES)

Argument

$$\texttt{NODES} : \texttt{collection}\begin{pmatrix}\texttt{index}-\texttt{int},\\ \texttt{father}-\texttt{dvar},\\ \texttt{prec}-\texttt{sint},\\ \texttt{inc}-\texttt{sint}\end{pmatrix}$$

Restrictions

required(NODES, [index, father, prec, inc])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.father ≥ 1
NODES.father $\leq$ |NODES|
NODES.prec ≥ 1
NODES.prec $\leq$ |NODES|
NODES.inc ≥ 1
NODES.inc $\leq$ |NODES|
NODES.inc $>$ NODES.index

Purpose

Enforce the construction of a *stably compatible* supertree that is compatible with several given trees. The notion of stable compatibility and its context are detailed in the **Usage** slot.

Example

$$\left\langle\begin{pmatrix}
\texttt{ind}-1 & \texttt{f}-4 & \texttt{p}-\{11,12\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-2 & \texttt{f}-3 & \texttt{p}-\{8,9\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-3 & \texttt{f}-4 & \texttt{p}-\{2,10\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-4 & \texttt{f}-5 & \texttt{p}-\{1,3\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-5 & \texttt{f}-7 & \texttt{p}-\{4,13\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-6 & \texttt{f}-2 & \texttt{p}-\{8,14\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-7 & \texttt{f}-7 & \texttt{p}-\{6,13\} & \texttt{inc}-\emptyset,\\
\texttt{ind}-8 & \texttt{f}-6 & \texttt{p}-\emptyset & \texttt{inc}-\{9,10,11,12,13,14\},\\
\texttt{ind}-9 & \texttt{f}-2 & \texttt{p}-\emptyset & \texttt{inc}-\{10,11,12,13\},\\
\texttt{ind}-10 & \texttt{f}-3 & \texttt{p}-\emptyset & \texttt{inc}-\{11,12,13\},\\
\texttt{ind}-11 & \texttt{f}-1 & \texttt{p}-\emptyset & \texttt{inc}-\{12,13\},\\
\texttt{ind}-12 & \texttt{f}-1 & \texttt{p}-\emptyset & \texttt{inc}-\{13\},\\
\texttt{ind}-13 & \texttt{f}-5 & \texttt{p}-\emptyset & \texttt{inc}-\{14\},\\
\texttt{ind}-14 & \texttt{f}-6 & \texttt{p}-\emptyset & \texttt{inc}-\emptyset
\end{pmatrix}\right\rangle$$

(ind for index, f for father, p for prec)

Figure 5.762 shows the two trees we want to merge. Note that the leaves a and f occur in both trees.

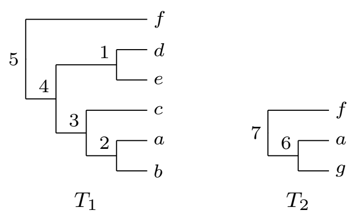

Figure 5.762: The two trees to merge

The left part of Figure 5.763 gives one way to merge the two previous trees. This solution corresponds to the ground instance provided by the example. Note that there exist 7 other ways to merge these two trees. They are respectively depicted by Figures 5.763 to 5.766.

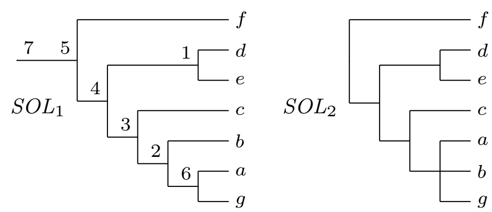

Figure 5.763: First solution (corresponding to the ground instance of the example) and second solution on how to merge the two trees T_1 and T_2 of Figure 5.762

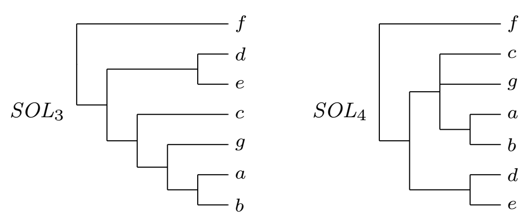

Figure 5.764: Third and fourth solutions on how to merge the two trees T_1 and T_2 of Figure 5.762

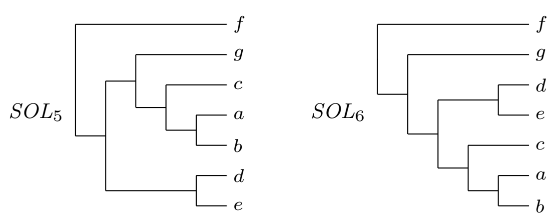

Figure 5.765: Fifth and sixth solutions on how to merge the two trees T_1 and T_2 of Figure 5.762

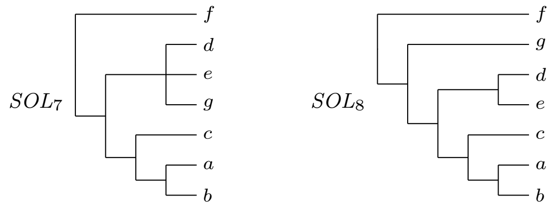

Figure 5.766: Seventh and eight solutions on how to merge the two trees T_1 and T_2 of Figure 5.762

Typical

$|$`NODES`$| > 2$
`range`(`NODES.father`) > 1

Symmetry

Items of `NODES` are permutable.

Usage

One objective of phylogeny is to construct the genealogy of the species, called the *tree of life*, whose leaves represent the contemporary species and whose internal nodes represent extinct species that are not necessarily named. An important problem in phylogeny is the construction of a supertree [83] that is compatible with several given trees. There are several definitions of tree compatibility in the literature:

- A tree $\mathcal{T}$ is *strongly compatible* with a tree $\mathcal{T}'$ if $\mathcal{T}'$ is topologically equivalent to a subtree $\mathcal{T}$ that respects the node labelling. [305]
- A tree $\mathcal{T}$ is *weakly compatible* with a tree $\mathcal{T}'$ if $\mathcal{T}'$ can be obtained from $\mathcal{T}$ by a series of arc contractions. [409]
- A tree $\mathcal{T}$ is *stably compatible* with a set $\mathcal{S}$ of trees if $\mathcal{T}$ is weakly compatible with each tree in $\mathcal{S}$ and each internal node of $\mathcal{T}$ can be labelled by at least one corresponding internal node of some tree in $\mathcal{S}$.

For the supertree problem, strong and weak compatibility coincide if and only if all the given trees are binary [305]. The existence of solutions is not lost when restricting weak compatibility to stable compatibility.

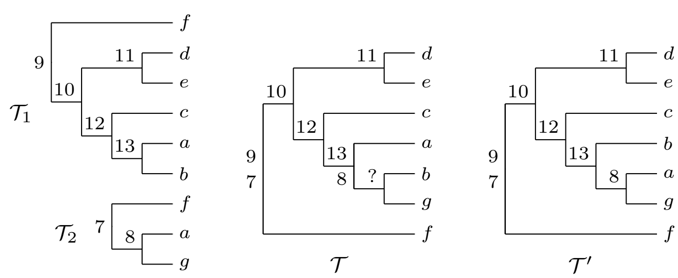

Figure 5.767: Supertree problem instance and two of its solutions

For example, the trees $\mathcal{T}_1$ and $\mathcal{T}_2$ of Figure 5.767 have $\mathcal{T}$ and $\mathcal{T}'$ as supertrees under both weak and strong compatibility. As shown, all the internal nodes of $\mathcal{T}'$ can be labelled by

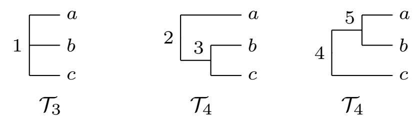

Figure 5.768: Three small phylogenetic trees

corresponding internal nodes of the two given trees, but this is not the case for the father of b and g in $\mathcal{T}$. Hence $\mathcal{T}$ and four other such supertrees are debatable because they speculate about the existence of extinct species that were not in any of the given trees. Consider also the three small trees in Figure 5.768: $\mathcal{T}_3$ and $\mathcal{T}_4$ have $\mathcal{T}_4$ as a supertree under weak compatibility, as it suffices to contract the arc $(3,2)$ to get $\mathcal{T}_3$ from $\mathcal{T}_4$. However, $\mathcal{T}_3$ and $\mathcal{T}_4$ have no supertree under strong compatibility, as the most recent common ancestor of b and c, denoted by $mrca(b,c)$, is the same as $mrca(a,b)$ in $\mathcal{T}_3$, namely 1, but not the same in $\mathcal{T}_4$, as $mrca(b,c) = 3$ is an evolutionary descendant of $mrca(a,b) = 2$. Also, $\mathcal{T}_4$ and $\mathcal{T}_5$ have neither weakly nor strongly compatible supertrees.

Under strong compatibility, a first supertree algorithm was given in [4], with an application for database management systems; it takes $O(l^2)$ time, where l is the number of leaves in the given trees. Derived algorithms have emerged from phylogeny, for example, *One-Tree* [305]. The first constraint program was proposed in [202], using standard, non-global constraints. Under weak compatibility, a phylogenetic supertree algorithm can be found in [409], for example. Under stable compatibility, the algorithm from computational linguistics of [87] has supertree construction as special case.

See also **root concept:** TREE.

Keywords **application area:** bioinformatics, phylogeny.

constraint type: graph constraint.

final graph structure: tree.

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	nodes1.father = nodes2.index
Graph property(ies)	• **MAX_NSCC** ≤ 1 • **NCC** $= 1$ • **MAX_ID** ≤ 2 • **PATH_FROM_TO**(index, index, prec) $= 1$ • **PATH_FROM_TO**(index, index, inc) $= 0$ • **PATH_FROM_TO**(index, inc, index) $= 0$

Graph model To each distinct leave (i.e., each species) of the trees to merge corresponds a vertex of the initial graph. To each internal vertex of the trees to merge corresponds also a vertex of the initial graph. Each vertex of the initial graph has the following attributes:

- An *index* corresponding to a unique identifier.
- A *father* corresponding to the father of the vertex in the final tree. Since the leaves of the trees to merge must remain leaves we remove the index value of all the leaves from all the father variables.
- A *set of precedence constraints* corresponding to all the arcs of the trees to merge.
- A *set of incomparability constraints* corresponding to the incomparable vertices of each tree to merge.

The arc constraint describes the fact that we link a vertex to its father variable. Finally we use the following six graph properties on our final graph:

- The first graph property **MAX_NSCC** ≤ 1 enforces the fact that the size of the largest strongly connected component does not exceed one. This avoid having circuits containing more than one vertex. In fact the root of the merged tree is a strongly connected component with a single vertex.
- The second graph property **NCC** $= 1$ imposes having only a single tree.
- The third graph property **PATH_FROM_TO**(index, index, prec) $= 1$ enforces for each vertex i a set of precedence constraints; for each vertex j of the precedence set there is a path from i to j in the final graph.
- The fourth graph property **MAX_ID** ≤ 2 enforces that the number of predecessors (i.e., arcs from a vertex to itself are not counted) of each vertex does not exceed 2 (i.e., the final graph is a binary tree).
- The fifth and sixth graph properties **PATH_FROM_TO**(index, index, inc) $=$ 0 and **PATH_FROM_TO**(index, inc, index) $= 0$ enforces for each vertex i a set of incomparability constraints; for each vertex j of the incomparability set there is neither a path from i to j, nor a path from j to i.

Figures 5.769 and 5.770 respectively show the precedence and the incomparability graphs associated with the **Example** slot. As it contains too many arcs the initial graph is not shown. Figures 5.763 shows the first solution satisfying all the precedence and incomparability constraints.

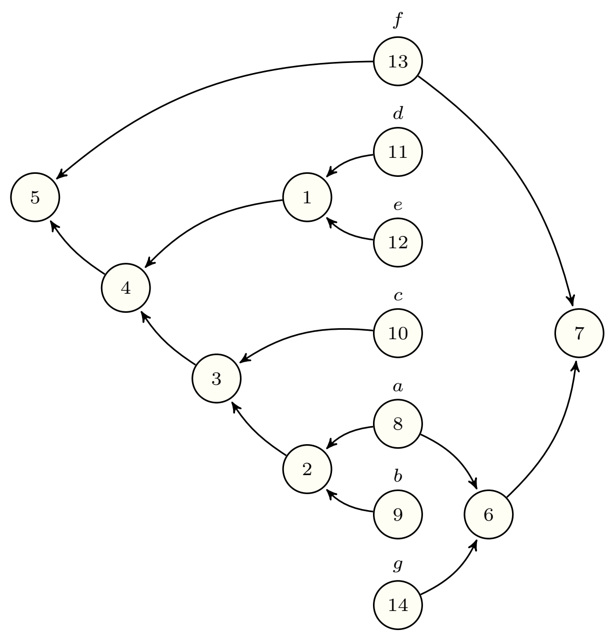

Figure 5.769: Precedence graph associated with the two trees to merge described by Figure 5.762

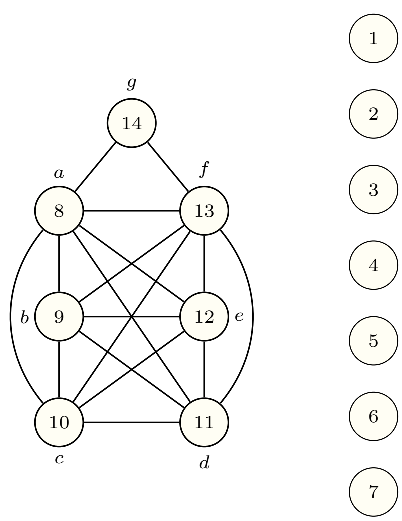

Figure 5.770: Incomparability graph associated with the two trees to merge described by Figure 5.762; the two cliques respectively correspond to the leaves of the two trees to merge.

5.381 STAGE_ELEMENT

DESCRIPTION LINKS GRAPH AUTOMATON

Origin Choco, derived from ELEMENT.

Constraint STAGE_ELEMENT(ITEM, TABLE)

Usual name STAGE_ELT

Synonym STAGE_ELEM.

Arguments

ITEM : collection(index−dvar, value−dvar)
TABLE : collection(low−int, up−int, value−int)

Restrictions

required(ITEM, [index, value])
$|\text{ITEM}| = 1$
$|\text{TABLE}| > 0$
required(TABLE, [low, up, value])
TABLE.low $\leq$ TABLE.up
increasing_seq(TABLE, [low])

Purpose

Let low_i, up_i and value_i respectively denote the values of the low, up and value attributes of the i^{th} item of the TABLE collection. First we have that: $\text{low}_i \leq \text{up}_i$ and $\text{up}_i + 1 = \text{low}_{i+1}$.
Second, the STAGE_ELEMENT constraint forces the following equivalence:
$\text{low}_i \leq \text{ITEM.index} \wedge \text{ITEM.index} \leq \text{up}_i \Leftrightarrow \text{ITEM.value} = \text{value}_i$.

Example

$$\left(\begin{array}{l}\langle \text{index}-5\ \text{value}-6\rangle,\\ \left\langle\begin{array}{lll}\text{low}-3 & \text{up}-7 & \text{value}-6,\\ \text{low}-8 & \text{up}-8 & \text{value}-8,\\ \text{low}-9 & \text{up}-14 & \text{value}-2,\\ \text{low}-15 & \text{up}-19 & \text{value}-9\end{array}\right\rangle\end{array}\right)$$

Figure 5.771 depicts the function associated with the items of the TABLE collection. The STAGE_ELEMENT constraint holds since:

- The value of ITEM[1].index is located between the values of the low and up attributes of the first item of the TABLE collection (i.e., $5 \in [3, 7]$).
- The value of ITEM[1].value corresponds to the value attribute of the first item of the TABLE collection (i.e., 6).

Typical

$|\text{TABLE}| > 1$
range(TABLE.value) > 1
TABLE.low $<$ TABLE.up

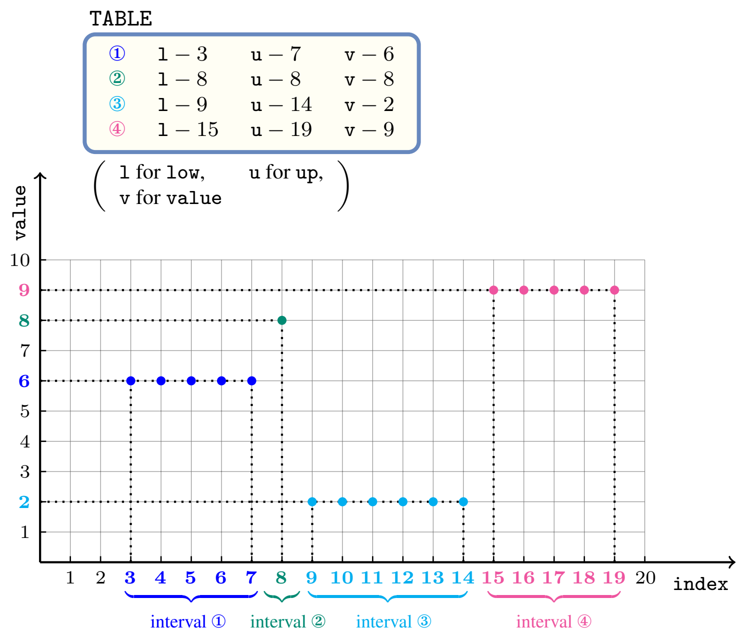

Figure 5.771: Function defined on four intervals ①, ②, ③ and ④ associated with the TABLE collection of the **Example** slot for linking the index and value attributes of the ITEM collection

Symmetry

All occurrences of two distinct values in ITEM.value or TABLE.value can be swapped; all occurrences of a value in ITEM.value or TABLE.value can be renamed to any unused value.

Arg. properties

- Functional dependency: ITEM.value determined by ITEM.index and TABLE.
- Suffix-extensible wrt. TABLE.

5.382 STRETCH_CIRCUIT

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [316]

Constraint STRETCH_CIRCUIT(VARIABLES, VALUES)

Usual name STRETCH

Arguments

VARIABLES : collection(var−dvar)
VALUES : collection(val−int, lmin−int, lmax−int)

Restrictions

|VARIABLES| > 0
required(VARIABLES, var)
|VALUES| > 0
required(VALUES, [val, lmin, lmax])
distinct(VALUES, val)
VALUES.lmin ≤ VALUES.lmax
VALUES.lmin ≤ |VARIABLES|
sum(VALUES.lmin) ≤ |VARIABLES|

Purpose

In order to define the meaning of the STRETCH_PATH constraint, we first introduce the notions of *stretch* and *span*. Let n be the number of variables of the collection VARIABLES and let i, j $(0 \leq i < n, 0 \leq j < n)$ be two positions within the collection of variables VARIABLES such that the following conditions apply:

- If $i \leq j$ then all variables $X_i, \ldots, X_j$ take a same value from the set of values of the val attribute.

  If $i > j$ then all variables $X_i, \ldots, X_{n-1}, X_0, \ldots, X_j$ take a same value from the set of values of the val attribute.
- $X_{(i-1) \bmod n}$ is different from X_i.
- $X_{(j+1) \bmod n}$ is different from X_j.

We call such a set of variables a *stretch*. The *span* of the stretch is equal to $1 + (j - i) \bmod n$, while the *value* of the stretch is X_i. We now define the condition enforced by the STRETCH_CIRCUIT constraint.

Each item $(\mathtt{val} - v, \mathtt{lmin} - s, \mathtt{lmax} - t)$ of the VALUES collection enforces the minimum value s as well as the maximum value t for the span of a stretch of value v.

Note that:

1. Having an item $(\mathtt{val} - v, \mathtt{lmin} - s, \mathtt{lmax} - t)$ with s strictly greater than 0 does not mean that value v should be assigned to one of the variables of collection VARIABLES. It rather means that, when value v is used, all stretches of value v must have a span that belong to interval $[s, t]$.
2. A variable of the collection VARIABLES may be assigned a value that is not defined in the VALUES collection.

Example

$$\left(\begin{array}{l}\langle 6,6,3,1,1,1,6,6\rangle, \\ \left\langle\begin{array}{lll}\texttt{val}-1 & \texttt{lmin}-2 & \texttt{lmax}-4, \\ \texttt{val}-2 & \texttt{lmin}-2 & \texttt{lmax}-3, \\ \texttt{val}-3 & \texttt{lmin}-1 & \texttt{lmax}-6, \\ \texttt{val}-6 & \texttt{lmin}-2 & \texttt{lmax}-4\end{array}\right\rangle\end{array}\right)$$

The STRETCH_CIRCUIT constraint holds since the sequence $6\ 6\ 3\ 1\ 1\ 1\ 6\ 6$ contains three stretches $6\ 6\ 6\ 6$, 3, and $1\ 1\ 1$ respectively verifying the following conditions:

- The span of the first stretch $6\ 6\ 6\ 6$ is located within interval $[2,4]$ (i.e., the limit associated with value 6).
- The span of the second stretch 3 is located within interval $[1,6]$ (i.e., the limit associated with value 3).
- The span of the third stretch $1\ 1\ 1$ is located within interval $[2,4]$ (i.e., the limit associated with value 1).

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$
$|\texttt{VARIABLES}| > |\texttt{VALUES}|$
$|\texttt{VALUES}| > 1$
$\texttt{VALUES.lmax} \leq |\texttt{VARIABLES}|$

Symmetries

- Items of VARIABLES can be shifted.
- Items of VALUES are permutable.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.

Usage

The article [316], which originally introduced the STRETCH constraint, quotes rostering problems as typical examples of use of this constraint.

Remark

We split the origin STRETCH constraint into the STRETCH_CIRCUIT and the STRETCH_PATH constraints that respectively use the *PATH LOOP* and *CIRCUIT LOOP* arc generators. We also reorganise the parameters: the VALUES collection describes the attributes of each value that can be assigned to the variables of the STRETCH_CIRCUIT constraint. Finally we skipped the pattern constraint that tells what values can follow a given value.

Algorithm

A first filtering algorithm was described in the original article of G. Pesant [316]. An algorithm that also generates explanations is given in [371]. The first filtering algorithm achieving arc-consistency is depicted in [219, 220]. This algorithm is based on dynamic programming and handles the fact that some values can be followed by only a given subset of values.

Reformulation

The STRETCH_CIRCUIT constraint can be reformulated in term of a STRETCH_PATH constraint. Let $LMAX$ denote the maximum value taken by the lmax attribute within the items of the collection VALUES, let n be the number of variables of the collection VARIABLES, and let $\delta = \min(LMAX, n)$. The first and second arguments of the STRETCH_PATH constraint are created in the following way:

- We pass to the STRETCH_PATH the variables of the collection VARIABLES to which we add the δ first variables of the collection VARIABLES.
- We pass to the STRETCH_PATH the values of the collection VALUES with the following modification: to each value v for which the corresponding lmax attribute is greater than or equal to n we reset its value to $n + \delta$.

Even if STRETCH_PATH can achieve arc-consistency this reformulation may not achieve arc-consistency since it duplicates variables.

Using this reformulation, the example

$$\text{STRETCH\_CIRCUIT}(\langle 6,6,3,1,1,1,6,6\rangle, \langle \texttt{val}-1\ \texttt{lmin}-2\ \texttt{lmax}-4,\ \texttt{val}-2\ \texttt{lmin}-2\ \texttt{lmax}-3,\ \texttt{val}-3\ \texttt{lmin}-1\ \texttt{lmax}-6,\ \texttt{val}-6\ \texttt{lmin}-2\ \texttt{lmax}-4\rangle)$$

of the **Example** slot is reformulated as:

$$\text{STRETCH\_PATH}(\langle 6,6,3,1,1,1,6,6,6,6,3,1,1,1\rangle, \langle \texttt{val}-1\ \texttt{lmin}-2\ \texttt{lmax}-4,\ \texttt{val}-2\ \texttt{lmin}-2\ \texttt{lmax}-3,\ \texttt{val}-3\ \texttt{lmin}-1\ \texttt{lmax}-6,\ \texttt{val}-6\ \texttt{lmin}-2\ \texttt{lmax}-4\rangle)$$

In the reformulation δ was equal to 6, and the VALUES collection was left unchanged since no lmax attribute was equal to the number of variables of the VARIABLES collection (i.e., 8).

common keyword: GROUP *(timetabling constraint)*, PATTERN *(sliding sequence constraint,timetabling constraint)*, SLIDING_DISTRIBUTION *(sliding sequence constraint)*, STRETCH_PATH *(sliding sequence constraint,timetabling constraint)*.

used in reformulation: STRETCH_PATH.

Keywords

characteristic of a constraint: cyclic.

constraint type: timetabling constraint, sliding sequence constraint.

filtering: dynamic programming, arc-consistency, duplicated variables.

For all items of VALUES:

Arc input(s)	VARIABLES
Arc generator	*CIRCUIT*$\mapsto$collection(variables1, variables2) *LOOP*$\mapsto$collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	• variables1.var = VALUES.val • variables2.var = VALUES.val
Graph property(ies)	• NOT_IN(**MIN_NCC**, 1, VALUES.lmin − 1) • **MAX_NCC**$\leq$ VALUES.lmax

Graph model Part (A) of Figure 5.775 shows the initial graphs associated with values 1, 2, 3 and 6 of the **Example** slot. Part (B) of Figure 5.775 shows the corresponding final graphs associated with values 1, 3 and 6. Since value 2 is not assigned to any variable of the VARIABLES collection the final graph associated with value 2 is empty. The STRETCH_CIRCUIT constraint holds since:

- For value 1 we have one connected component for which the number of vertices is greater than or equal to 2 and less than or equal to 4,
- For value 2 we do not have any connected component,
- For value 3 we have one connected component for which the number of vertices is greater than or equal to 1 and less than or equal to 6,
- For value 6 we have one connected component for which the number of vertices is greater than or equal to 2 and less than or equal to 4.

5.383 STRETCH_PATH

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin [316]

Constraint STRETCH_PATH(VARIABLES, VALUES)

Usual name STRETCH

Arguments

VARIABLES : collection(var−dvar)
VALUES : collection(val−int, lmin−int, lmax−int)

Restrictions

|VARIABLES| > 0
required(VARIABLES, var)
|VALUES| > 0
required(VALUES, [val, lmin, lmax])
distinct(VALUES, val)
VALUES.lmin ≥ 0
VALUES.lmin ≤ VALUES.lmax
VALUES.lmin ≤ |VARIABLES|

Purpose

In order to define the meaning of the STRETCH_PATH constraint, we first introduce the notions of *stretch* and *span*. Let n be the number of variables of the collection VARIABLES. Let $X_i, \ldots, X_j$ $(1 \leq i \leq j \leq n)$ be consecutive variables of the collection of variables VARIABLES such that the following conditions apply:

- All variables $X_i, \ldots, X_j$ take a same value from the set of values of the val attribute,
- $i = 1$ or X_{i-1} is different from X_i,
- $j = n$ or X_{j+1} is different from X_j.

We call such a set of variables a *stretch*. The *span* of the stretch is equal to $j - i + 1$, while the *value* of the stretch is X_i. We now define the condition enforced by the STRETCH_PATH constraint.

Each item (val $- v$, lmin $- s$, lmax $- t$) of the VALUES collection enforces the minimum value s as well as the maximum value t for the span of a stretch of value v over consecutive variables of the VARIABLES collection.

Note that:

1. Having an item (val $- v$, lmin $- s$, lmax $- t$) with s strictly greater than 0 does not mean that value v should be assigned to one of the variables of collection VARIABLES. It rather means that, when value v is used, all stretches of value v must have a span that belong to interval $[s, t]$.
2. A variable of the collection VARIABLES may be assigned a value that is not defined in the VALUES collection.

Example

$$\left(\begin{array}{l}\langle 6,6,3,1,1,1,6,6\rangle, \\ \left\langle\begin{array}{lll}\texttt{val}-1 & \texttt{lmin}-2 & \texttt{lmax}-4, \\ \texttt{val}-2 & \texttt{lmin}-2 & \texttt{lmax}-3, \\ \texttt{val}-3 & \texttt{lmin}-1 & \texttt{lmax}-6, \\ \texttt{val}-6 & \texttt{lmin}-2 & \texttt{lmax}-2\end{array}\right\rangle\end{array}\right)$$

The STRETCH_PATH constraint holds since the sequence 6 6 3 1 1 1 6 6 contains four stretches 6 6, 3, 1 1 1, and 6 6 respectively verifying the following conditions:

- The span of the first stretch 6 6 is located within interval $[2, 2]$ (i.e., the limit associated with value 6).
- The span of the second stretch 3 is located within interval $[1, 6]$ (i.e., the limit associated with value 3).
- The span of the third stretch 1 1 1 is located within interval $[2, 4]$ (i.e., the limit associated with value 1).
- The span of the fourth stretch 6 6 is located within interval $[2, 2]$ (i.e., the limit associated with value 6).

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$
$|\texttt{VARIABLES}| > |\texttt{VALUES}|$
$|\texttt{VALUES}| > 1$
$\texttt{sum}(\texttt{VALUES.lmin}) \leq |\texttt{VARIABLES}|$
$\texttt{VALUES.lmax} \leq |\texttt{VARIABLES}|$

Symmetries

- Items of VARIABLES can be reversed.
- Items of VALUES are permutable.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.

Usage

The article [316], which originally introduced the STRETCH constraint, quotes rostering problems as typical examples of use of this constraint.

Remark

We split the original STRETCH constraint into the STRETCH_PATH and the STRETCH_CIRCUIT constraints that respectively use the *PATH LOOP* and the *CIRCUIT LOOP* arc generators. We also reorganise the parameters: the VALUES collection describes the attributes of each value that can be assigned to the variables of the STRETCH_PATH constraint. Finally we skipped the pattern constraint that tells what values can follow a given value. A extension of this constraint (i.e., stretch plus pattern), called FORCED_SHIFT_STRETCH, where one can specify for each value v with a 0-1 variable, whether it should occur at least once or not at all, was proposed in [220]. By reduction to Hamiltonian path it was shown that enforcing arc-consistency for FORCED_SHIFT_STRETCH is NP-hard [220].

Algorithm

A first filtering algorithm was described in the original article of G. Pesant [316]. A second filtering algorithm, based on dynamic programming, achieving arc-consistency is depicted in [219, 220]. It also handles the fact that some values can be followed by only a given subset of values. An other alternative achieving arc-consistency is to use the automaton described in the **Automaton** slot.

Systems STRETCHPATH in **Choco**, STRETCH in **JaCoP**.

generalisation: STRETCH_PATH_PARTITION *(*`variable` *replaced by* `variable` $\in$ `partition`*)*.

uses in its reformulation: STRETCH_CIRCUIT.

Keywords **characteristic of a constraint:** automaton, automaton without counters, reified automaton constraint.

combinatorial object: sequence.

constraint network structure: Berge-acyclic constraint network.

constraint type: timetabling constraint, sliding sequence constraint.

filtering: dynamic programming, arc-consistency.

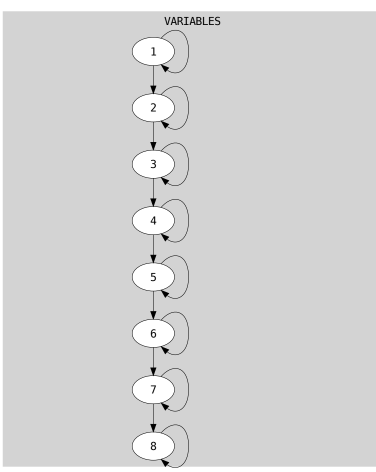
final graph structure: consecutive loops are connected.

For all items of `VALUES`:

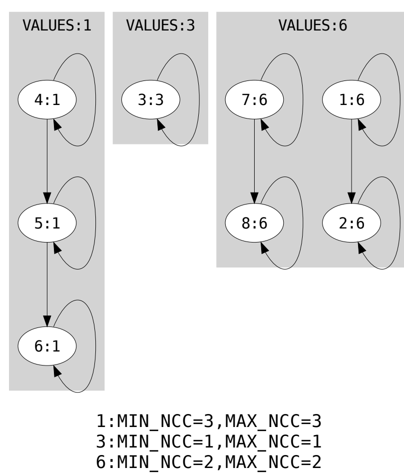
Arc input(s)	`VARIABLES`
Arc generator	*PATH* $\mapsto$ `collection(variables1, variables2)` *LOOP* $\mapsto$ `collection(variables1, variables2)`
Arc arity	2
Arc constraint(s)	• `variables1.var` = `VALUES.val` • `variables2.var` = `VALUES.val`
Graph property(ies)	• NOT_IN(**MIN_NCC**, 1, `VALUES.lmin` − 1) • **MAX_NCC** ≤ `VALUES.lmax`

Graph model Part (A) of Figure 5.776 shows the initial graphs associated with values 1, 2, 3 and 6 of the **Example** slot. Part (B) of Figure 5.776 shows the corresponding final graphs associated with values 1, 3 and 6. Since value 2 is not assigned to any variable of the `VARIABLES` collection the final graph associated with value 2 is empty. The STRETCH_PATH constraint holds since:

- For value 1 we have one connected component for which the number of vertices 3 is greater than or equal to 2 and less than or equal to 4,
- For value 2 we do not have any connected component,
- For value 3 we have one connected component for which the number of vertices 1 is greater than or equal to 1 and less than or equal to 6,
- For value 6 we have two connected components that both contain two vertices: this is greater than or equal to 2 and less than or equal to 2.



(A)



(B)

Figure 5.776: Initial and final graph of the STRETCH_PATH constraint

During the presentation of this constraint at CP'2001 the following point was mentioned: it could be useful to allow domain variables for the minimum and the maximum values of a stretch. This could be achieved in the following way: the `lmin` (respectively `lmax`) attribute would now be a domain variable that gives the size of the shortest (respectively longest) stretch. Finally within the **Graph property(ies)** slot we would replace $\geq$ (and $\leq$) by $=$.

Automaton Let n and m respectively denote the quantities $|\texttt{VARIABLES}|$ and $|\texttt{VALUES}|$. Furthermore, let $\texttt{val}_i$, $\texttt{lmin}_i$ and $\texttt{lmax}_i$, $(i \in [1, m])$, respectively be shortcuts for the expressions $\texttt{VALUES}[i]$.val, $\texttt{VALUES}[i]$.lmin and $\texttt{VALUES}[i]$.lmax. Without loss of generality, we assume that all the lmin attributes of the items of the VALUES collection are at least equal to 1. The following automaton $\mathcal{A}$ involving $1 + \texttt{lmax}_1 + \texttt{lmax}_2 + \cdots + \texttt{lmax}_m$ states only accepts solutions to the STRETCH_PATH constraint. Automaton $\mathcal{A}$ has the following states:

- an initial state s that is also an accepting state,
- $\forall i \in [1, m], \forall j \in [1, \texttt{lmin}_i - 1]$, a non-accepting state $s_{i,j}$,
- $\forall i \in [1, m], \forall j \in [\texttt{lmin}_i, \texttt{lmax}_i]$, an accepting state $s_{i,j}$.

Transitions of $\mathcal{A}$ are defined in the following way:

- $\forall i \in [1, m]$, a transition from s to $s_{i,1}$ labelled by condition $X_l = \texttt{val}_i$,
- a transition from s to s labelled by condition $X_l \neq \texttt{val}_1 \wedge X_l \neq \texttt{val}_2 \wedge \cdots \wedge X_l \neq \texttt{val}_m$,
- $\forall i \in [1, m], \forall j \in [\texttt{lmin}_i, \texttt{lmax}_i]$, a transition from $s_{i,j}$ to s labelled by condition $X_l \neq \texttt{val}_1 \wedge X_l \neq \texttt{val}_2 \wedge \cdots \wedge X_l \neq \texttt{val}_m$,
- $\forall i \in [1, m], \forall j \in [1, \texttt{lmax}_i - 1]$, a transition from $s_{i,j}$ to $s_{i,j+1}$ labelled by condition $X_l = \texttt{val}_i$,
- $\forall i \in [1, m], \forall j \in [\texttt{lmin}_i, \texttt{lmax}_i], \forall k \neq i \in [1, m]$, a transition from $s_{i,j}$ to $s_{k,1}$ labelled by condition $X_l = \texttt{val}_k$.

Figure 5.777 depicts the automaton associated with the STRETCH_PATH constraint of the **Example** slot. Transitions labels 0, 1, 2, 3 and 4 respectively correspond to the conditions $X_l \neq 1 \wedge X_l \neq 2 \wedge X_l \neq 3 \wedge X_l \neq 6$, $X_l = 1$, $X_l = 2$, $X_l = 3$, $X_l = 6$ (since values 1, 2, 3 and 6 respectively correspond to the values of the first, second, third and fourth item of the VALUES collection). The STRETCH_PATH constraint holds since the corresponding sequence of visited states, s s_{41} s_{42} s_{31} s_{11} s_{12} s_{13} s_{41} s_{42}, ends up in an accepting state (i.e., accepting states are denoted graphically by a double circle in the figure).

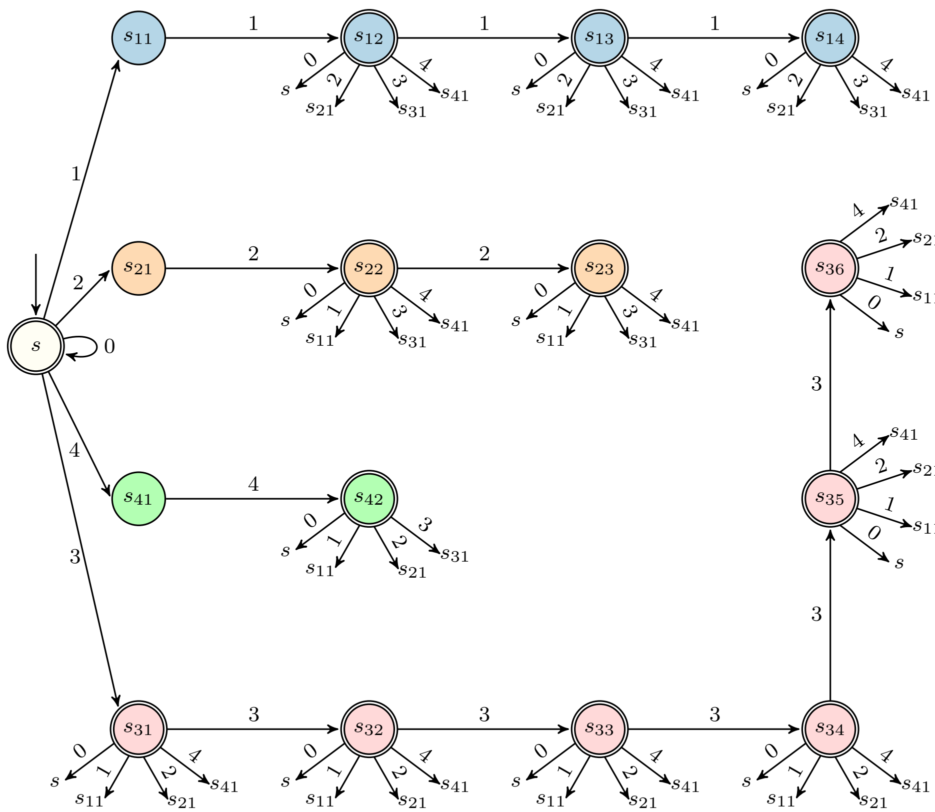


Figure 5.777: Automaton of the STRETCH_PATH constraint of the **Example** slot (states related to a same stretch have the same colour)

5.384 STRETCH_PATH_PARTITION

▶ ▷ ◁ ◀

DESCRIPTION LINKS

Origin Derived from STRETCH_PATH.

Constraint STRETCH_PATH_PARTITION(VARIABLES, PARTLIMITS)

Synonym STRETCH.

Type

VALUES : collection(val−int)

Arguments

VARIABLES : collection(var−dvar)
PARTLIMITS : collection(p − VALUES, lmin−int, lmax−int)

Restrictions

$|\texttt{VALUES}| \geq 1$
required(VALUES, val)
distinct(VALUES, val)
$|\texttt{VARIABLES}| > 0$
required(VARIABLES, var)
$|\texttt{PARTLIMITS}| > 0$
required(PARTLIMITS, [p, lmin, lmax])
$\texttt{PARTLIMITS.lmin} \geq 0$
$\texttt{PARTLIMITS.lmin} \leq \texttt{PARTLIMITS.lmax}$
$\texttt{PARTLIMITS.lmin} \leq |\texttt{VARIABLES}|$

Purpose

In order to define the meaning of the STRETCH_PATH_PARTITION constraint, we first introduce the notions of *stretch* and *span*. Let n be the number of variables of the collection VARIABLES. Let $X_i, \ldots, X_j$ $(1 \leq i \leq j \leq n)$ be consecutive variables of the collection of variables VARIABLES such that the following conditions apply:

- All variables $X_i, \ldots, X_j$ take their values in the same partition of the PARTLIMITS collection (i.e., $\exists l \in [1, |\texttt{PARTLIMITS}|]$ such that $\forall k \in [i, j] : X_k \in \texttt{PARTLIMITS}[l].p$),
- $i = 1$ or X_{i-1} is different from X_i,
- $j = n$ or X_{j+1} is different from X_j.

We call such a set of variables a *stretch*. The *span* of the stretch is equal to $j - i + 1$, while the *value* of the stretch is l. We now define the condition enforced by the STRETCH_PATH_PARTITION constraint.

Each item $\texttt{PARTLIMITS}[l] = (\texttt{p} - values, \texttt{lmin} - s, \texttt{lmax} - t)$ of the PARTLIMITS collection enforces the minimum value s as well as the maximum value t for the span of a stretch of value l over consecutive variables of the VARIABLES collection.

Note that:

1. Having an item $\texttt{PARTLIMITS}[l] = (\texttt{p} - values, \texttt{lmin} - s, \texttt{lmax} - t)$ with s strictly greater than 0 does not mean that values of $values$ should be assigned to one of the variables of collection VARIABLES. It rather means that, when a value of $values$ is used, all stretches of value l must have a span that belong to interval $[s, t]$.
2. A variable of the collection VARIABLES may be assigned a value that is not defined in the attribute p of the PARTLIMITS collection.

Example

$$\left(\begin{array}{l} \langle 1, 2, 0, 0, 2, 2, 2, 0 \rangle, \\ \left\langle \begin{array}{lll} \texttt{p} - \langle 1, 2 \rangle & \texttt{lmin} - 2 & \texttt{lmax} - 4, \\ \texttt{p} - \langle 3 \rangle & \texttt{lmin} - 0 & \texttt{lmax} - 2 \end{array} \right\rangle \end{array} \right)$$

The STRETCH_PATH_PARTITION constraint holds since the sequence 1 2 0 0 2 2 2 0 contains two stretches 1 2, and 2 2 2 respectively verifying the following conditions:

- The span of the first stretch 1 2 is located within interval $[2, 4]$ (i.e., the limit associated with item $\texttt{PARTLIMITS}[1]$).
- The span of the second stretch 2 2 2 is located within interval $[2, 4]$ (i.e., the limit associated with item $\texttt{PARTLIMITS}[1]$).

Typical

$|\texttt{VARIABLES}| > 1$
$\texttt{range}(\texttt{VARIABLES.var}) > 1$
$|\texttt{VARIABLES}| > |\texttt{PARTLIMITS}|$
$|\texttt{PARTLIMITS}| > 1$
$\texttt{sum}(\texttt{PARTLIMITS.lmin}) \leq |\texttt{VARIABLES}|$
$\texttt{PARTLIMITS.lmax} \leq |\texttt{VARIABLES}|$

Symmetries

- Items of VARIABLES can be reversed.
- Items of PARTLIMITS are permutable.
- Items of PARTLIMITS.p are permutable.
- All occurrences of two distinct tuples of values in VARIABLES.var or PARLIMITS.p.val can be swapped; all occurrences of a tuple of values in VARIABLES.var or PARLIMITS.p.val can be renamed to any unused tuple of values.

5.385 STRICT_LEX2

► ▷ ◁ ◀ DESCRIPTION LINKS

Origin [179]

Constraint STRICT_LEX2(MATRIX)

Type VECTOR : collection(var−dvar)

Argument MATRIX : collection(vec − VECTOR)

Restrictions
$|\texttt{VECTOR}| \geq 1$
required(VECTOR, var)
required(MATRIX, vec)
same_size(MATRIX, vec)

Purpose Given a matrix of domain variables, enforces that both adjacent rows, and adjacent columns are lexicographically ordered (adjacent rows and adjacent columns cannot be equal).

Example $(\langle \texttt{vec} - \langle 2, 2, 3\rangle, \texttt{vec} - \langle 2, 3, 1\rangle\rangle)$

The STRICT_LEX2 constraint holds since:

- The first row $\langle 2, 2, 3\rangle$ is lexicographically strictly less than the second row $\langle 2, 3, 1\rangle$.
- The first column $\langle 2, 2\rangle$ is lexicographically strictly less than the second column $\langle 2, 3\rangle$.
- The second column $\langle 2, 3\rangle$ is lexicographically strictly less than the third column $\langle 3, 1\rangle$.

Typical
$|\texttt{VECTOR}| > 1$
$|\texttt{MATRIX}| > 1$

Symmetry One and the same constant can be added to the var attribute of all items of MATRIX.vec.

Usage A *symmetry-breaking* constraint.

Reformulation The STRICT_LEX2 constraint can be expressed as a conjunction of two LEX_CHAIN_LESS constraints: A first LEX_CHAIN_LESS constraint on the MATRIX argument and a second LEX_CHAIN_LESS constraint on the transpose of the MATRIX argument.

Systems STRICT_LEX2 in **MiniZinc**.

5.388 STRONGLY_CONNECTED

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [6]

Constraint STRONGLY_CONNECTED(NODES)

Argument NODES : collection(index−int, succ−svar)

Restrictions
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES, index)

Purpose Consider a digraph G described by the NODES collection. Select a subset of arcs of G so that we have a single strongly connected component involving all vertices of G.

Example

$$\left(\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-\{2\},\\ \texttt{index}-2 & \texttt{succ}-\{3\},\\ \texttt{index}-3 & \texttt{succ}-\{2,5\},\\ \texttt{index}-4 & \texttt{succ}-\{1\},\\ \texttt{index}-5 & \texttt{succ}-\{4\}\end{array}\right\rangle\right)$$

The STRONGLY_CONNECTED constraint holds since the NODES collection depicts a graph involving a single strongly connected component (i.e., since we have a circuit visiting successively the vertices 1, 2, 3, 5, and 4).

Typical |NODES| > 2

Symmetry Items of NODES are permutable.

Algorithm The sketch of a filtering algorithm for the STRONGLY_CONNECTED constraint is given in [151, page 89].

See also
common keyword: LINK_SET_TO_BOOLEANS *(constraint involving set variables)*.
implied by: CONNECTED.
related: CIRCUIT *(one single strongly connected component in the final solution)*.

Keywords
constraint arguments: constraint involving set variables.
constraint type: graph constraint.
filtering: linear programming.
final graph structure: strongly connected component.

Arc input(s) NODES

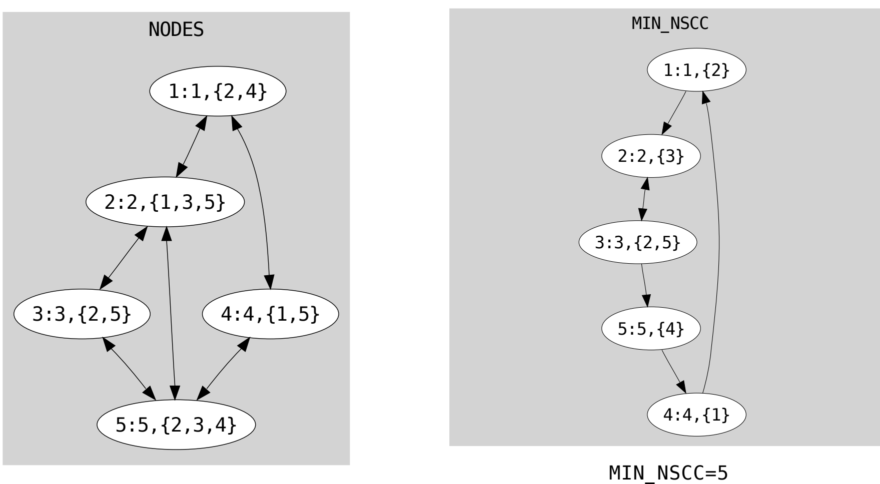
Arc generator *CLIQUE*$\mapsto$collection(nodes1, nodes2)

Arc arity 2

Arc constraint(s) IN_SET(nodes2.index, nodes1.succ)

Graph property(ies) **MIN_NSCC**$=$ |NODES|

Graph model Part (A) of Figure 5.784 shows the initial graph from which we start. It is derived from the set associated with each vertex. Each set describes the potential values of the succ attribute of a given vertex. Part (B) of Figure 5.784 gives the final graph associated with the **Example** slot. The STRONGLY_CONNECTED constraint holds since the final graph contains a single strongly connected component mentioning every vertex of the initial graph.



(A) **(B)**

Figure 5.784: Initial and final graph of the STRONGLY_CONNECTED set constraint

Signature Since the maximum number of vertices of the final graph is equal to |NODES| we can rewrite the graph property **MIN_NSCC** $=$ |NODES| to **MIN_NSCC** $\geq$ |NODES| and simplify $\underline{\textbf{MIN\_NSCC}}$ to $\overline{\textbf{MIN\_NSCC}}$.

5.389 SUBGRAPH_ISOMORPHISM

DESCRIPTION LINKS

Origin [288]

Constraint SUBGRAPH_ISOMORPHISM(NODES_PATTERN, NODES_TARGET, FUNCTION)

Arguments

```
NODES_PATTERN : collection(index-int, succ-sint)
NODES_TARGET  : collection(index-int, succ-svar)
FUNCTION      : collection(image-dvar)
```

Restrictions

```
required(NODES_PATTERN, [index, succ])
NODES_PATTERN.index ≥ 1
NODES_PATTERN.index ≤ |NODES_PATTERN|
distinct(NODES_PATTERN, index)
NODES_PATTERN.succ ≥ 1
NODES_PATTERN.succ ≤ |NODES_PATTERN|
required(NODES_TARGET, [index, succ])
NODES_TARGET.index ≥ 1
NODES_TARGET.index ≤ |NODES_TARGET|
distinct(NODES_TARGET, index)
NODES_TARGET.succ ≥ 1
NODES_TARGET.succ ≤ |NODES_TARGET|
required(FUNCTION, [image])
FUNCTION.image ≥ 1
FUNCTION.image ≤ |NODES_TARGET|
distinct(FUNCTION, image)
|FUNCTION| = |NODES_PATTERN|
```

Purpose

Given two directed graphs PATTERN and TARGET enforce a one to one correspondence, defined by the function FUNCTION, between the vertices of the graph PATTERN and the vertices of an induced subgraph of TARGET so that, if there is an arc from u to v in the graph PATTERN, then there is also an arc from the image of u to the image of v in the induced subgraph of TARGET. The vertices of both graphs are respectively defined by the two collections of vertices NODES_PATTERN and NODES_TARGET. Within collection NODES_PATTERN the set of successors of each node is fixed, while this is not the case for the collection NODES_TARGET. This stems from the fact that the TARGET graph is not fixed (i.e., the lower and upper bounds of the target graph are specified when we post the SUBGRAPH_ISOMORPHISM constraint, while the induced subgraph of a solution to the SUBGRAPH_ISOMORPHISM constraint corresponds to a graph for which the upper and lower bounds are identical).

Example

$$\left(\begin{array}{l}\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-\{2,4\},\\ \texttt{index}-2 & \texttt{succ}-\{1,3,4\},\\ \texttt{index}-3 & \texttt{succ}-\emptyset,\\ \texttt{index}-4 & \texttt{succ}-\emptyset\end{array}\right\rangle,\\ \left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-\emptyset,\\ \texttt{index}-2 & \texttt{succ}-\{3,4,5\},\\ \texttt{index}-3 & \texttt{succ}-\emptyset,\\ \texttt{index}-4 & \texttt{succ}-\{2,5\},\\ \texttt{index}-5 & \texttt{succ}-\emptyset\end{array}\right\rangle,\\ \langle 4,2,3,5\rangle\end{array}\right)$$

Figure 5.785 gives the pattern (see Part (A)) and target graph (see Part (B)) of the **Example** slot as well as the one to one correspondence (see Part (C)) between the pattern graph and the induced subgraph of the target graph. The SUBGRAPH_ISOMORPHISM constraint since:

- To the arc from vertex 1 to vertex 4 in the pattern graph corresponds the arc from vertex 4 to 5 in the induced subgraph of the target graph.
- To the arc from vertex 1 to vertex 2 in the pattern graph corresponds the arc from vertex 4 to 2 in the induced subgraph of the target graph.
- To the arc from vertex 2 to vertex 1 in the pattern graph corresponds the arc from vertex 2 to 4 in the induced subgraph of the target graph.
- To the arc from vertex 2 to vertex 4 in the pattern graph corresponds the arc from vertex 2 to 5 in the induced subgraph of the target graph.
- To the arc from vertex 2 to vertex 3 in the pattern graph corresponds the arc from vertex 2 to 3 in the induced subgraph of the target graph.

Typical

$|\texttt{NODES\_PATTERN}| > 1$
$|\texttt{NODES\_TARGET}| > 1$

Symmetries

- Items of NODES_PATTERN are permutable.
- Items of NODES_TARGET are permutable.

Usage

Within the context of constraint programming the constraint was used for finding symmetries [336, 338, 337].

Algorithm

[423, 352, 265, 456].

See also

related: GRAPH_ISOMORPHISM.

Keywords

constraint arguments: constraint involving set variables.

constraint type: predefined constraint, graph constraint.

symmetry: symmetry.

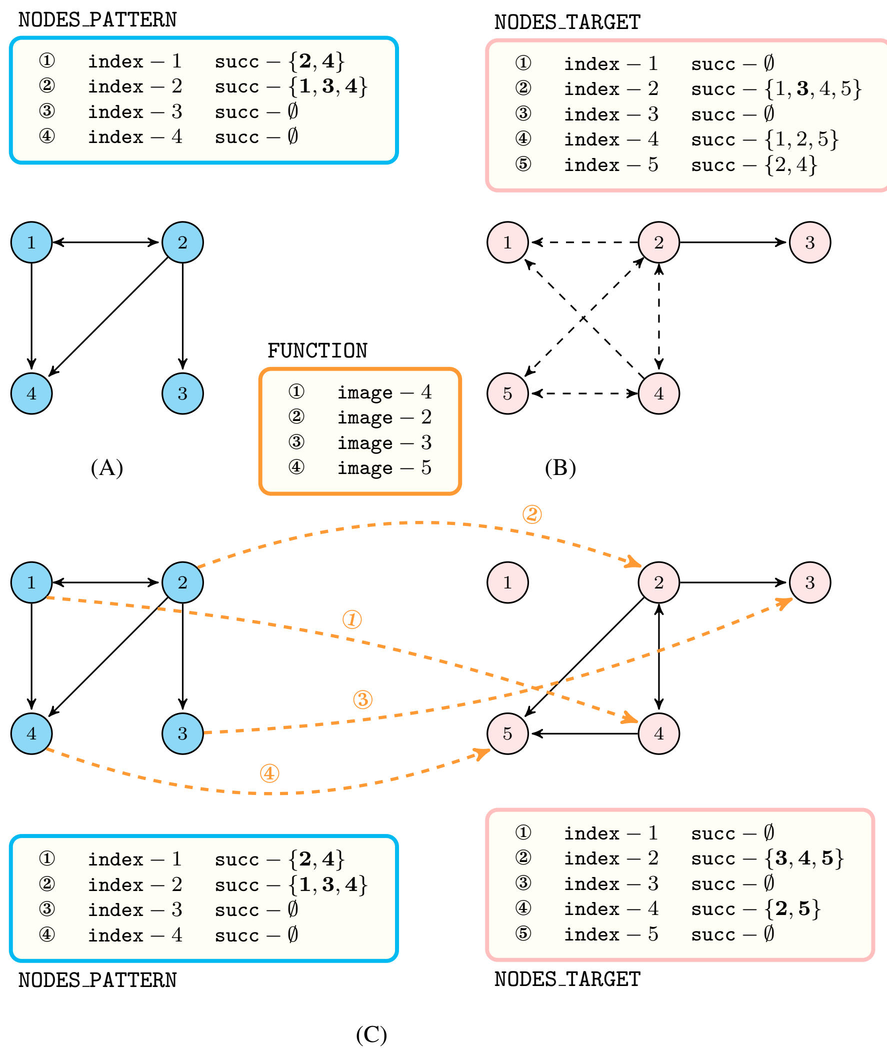


Figure 5.785: Illustration of the **Example** slot: (A) The pattern graph, (B) a possible initial target graph – plain arcs must belong to the induced subgraph, while dotted arcs may or may not belong to the induced subgraph – and (C) the correspondence, denoted by thick dashed arcs, between the vertices of the pattern graph and the vertices of the induced subgraph of the target graph. Within a set variable a bold value (respectively a plain value) represents a value that for sure belong (respectively that may belong) to the set.

5.390 SUM

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [455].

Constraint sum(INDEX, SETS, CONSTANTS, S)

Synonym SUM_PRED.

Arguments

INDEX	:	dvar
SETS	:	collection(ind−int, set−sint)
CONSTANTS	:	collection(cst−int)
S	:	dvar

Restrictions

$|\texttt{SETS}| \geq 1$
required(SETS, [ind, set])
distinct(SETS, ind)
$|\texttt{CONSTANTS}| \geq 1$
required(CONSTANTS, cst)

Purpose S is equal to the sum of the constants of CONSTANTS corresponding to the $\texttt{INDEX}^{th}$ set of the SETS collection.

Example

$$\left(\begin{array}{l} 8, \left\langle \begin{array}{ll} \texttt{ind}-8 & \texttt{set}-\{2,3\}, \\ \texttt{ind}-1 & \texttt{set}-\{3\}, \\ \texttt{ind}-3 & \texttt{set}-\{1,4,5\}, \\ \texttt{ind}-6 & \texttt{set}-\{2,4\} \end{array} \right\rangle, \\ \langle 4,9,1,3,1\rangle, 10 \end{array}\right)$$

The SUM constraint holds since its last argument S = 10 is equal to the sum of the 2^{th} and 3^{th} items of the collection $\langle 4,9,1,3,1\rangle$. As illustrated by Figure 5.786, this stems from the fact that its first argument INDEX = 8 corresponds to the value of the ind attribute of the first item of the SETS collection. Consequently the corresponding set $\{2,3\}$ is used for summing the 2^{th} and 3^{th} items of the CONSTANTS collection.

Typical

$|\texttt{SETS}| > 1$
$|\texttt{CONSTANTS}| > |\texttt{SETS}|$
range(CONSTANTS.cst) > 1

Symmetry Items of SETS are permutable.

Arg. properties Functional dependency: S determined by INDEX, SETS and CONSTANTS.

Usage In his article introducing the SUM constraint, Tallys H. Yunes mentions the *Sequence Dependent Cumulative Cost Problem* as the subproblem that originally motivates this constraint.

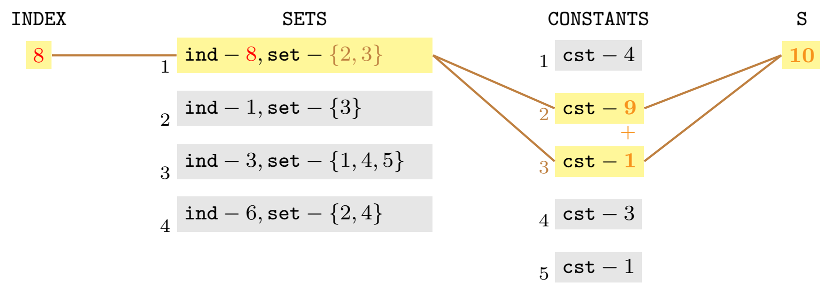

Figure 5.786: Illustration of the correspondence between the arguments of the SUM(INDEX, SETS, CONSTANTS, S) constraint in the context of the **Example** slot (from right to left, $\mathtt{S} = 10$ is equal to the sum of the constants 9 and 1 corresponding to the indices 2 and 3 of the set for which the ind attribute is equal to $\mathtt{INDEX} = 8$)

Remark The SUM constraint is called SUM_PRED in **MiniZinc** (http://www.minizinc.org/).

Algorithm The article [455] gives the convex hull relaxation of the SUM constraint.

Systems SUM_PRED in **MiniZinc**.

See also **common keyword:** ELEMENT *(data constraint)*, SUM_CTR, SUM_SET *(sum)*.

used in graph description: IN_SET.

Keywords **characteristic of a constraint:** convex hull relaxation, sum.

constraint type: data constraint.

filtering: linear programming.

modelling: functional dependency.

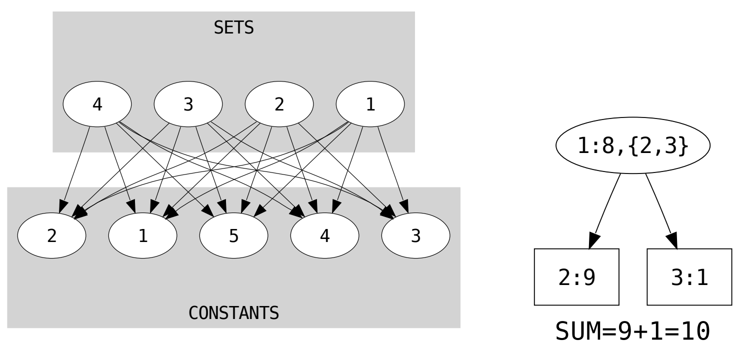
Arc input(s)	SETS CONSTANTS
Arc generator	*PRODUCT* $\mapsto$ collection(sets, constants)
Arc arity	2
Arc constraint(s)	• INDEX = sets.ind • IN_SET(constants.key, sets.set)
Graph property(ies)	**SUM**(CONSTANTS, cst) = S

Graph model According to the value assigned to INDEX the arc constraint selects for the final graph:

- The INDEXth item of the SETS collection,
- The items of the CONSTANTS collection for which the key correspond to the indices of the INDEXth set of the SETS collection.

Finally, since we use the **SUM** graph property on the cst attribute of the CONSTANTS collection, the last argument S of the SUM constraint is equal to the sum of the constants associated with the vertices of the final graph.

Parts (A) and (B) of Figure 5.787 respectively show the initial and final graph associated with the **Example** slot. Since we use the **SUM** graph property we show the vertices from which we compute S in a box.



(A) **(B)**

Figure 5.787: Initial and final graph of the SUM constraint

5.391 SUM_CTR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Arithmetic constraint.

Constraint SUM_CTR(VARIABLES, CTR, VAR)

Synonyms CONSTANT_SUM, SUM, LINEAR, SCALAR_PRODUCT.

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint the sum of a set of domain variables. More precisely, let S denote the sum of the variables of the VARIABLES collection (when the collection is empty the corresponding sum is equal to 0). Enforce the following constraint to hold: S CTR VAR.

Example $(\langle 1, 1, 4\rangle, =, 6)$

The SUM_CTR constraint holds since the condition $1 + 1 + 4 = 6$ is satisfied.

Typical

$|\text{VARIABLES}| > 1$
range(VARIABLES.var) > 1
CTR $\in [=, <, \geq, >, \leq]$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Contractible wrt. VARIABLES when CTR $\in [<, \leq]$ and minval(VARIABLES.var) ≥ 0.
- Contractible wrt. VARIABLES when CTR $\in [\geq, >]$ and maxval(VARIABLES.var) ≤ 0.
- Extensible wrt. VARIABLES when CTR $\in [\geq, >]$ and minval(VARIABLES.var) $\geq$ 0.
- Extensible wrt. VARIABLES when CTR $\in [<, \leq]$ and maxval(VARIABLES.var) $\leq$ 0.
- Aggregate: VARIABLES(union), CTR(id), VAR(+).

Remark J.-C. Régin *et al.* show in [365, 366] how to handle a SUM_CTR constraint subject of a set of difference constraints.

When CTR corresponds to $=$ this constraint is referenced under the names CONSTANT_SUM in KOALOG (http://www.koalog.com/php/index.php) and SUM in **JaCoP** (http://www.jacop.eu/).

Systems EQUATION in **Choco**, LINEAR in **Gecode**, SCALAR_PRODUCT in **SICStus**.

Used in BIN_PACKING, CUMULATIVE, CUMULATIVE_CONVEX, CUMULATIVE_WITH_LEVEL_OF_PRIORITY, CUMULATIVES, INDEXED_SUM, INTERVAL_AND_SUM, RELAXED_SLIDING_SUM, SLIDING_SUM, SLIDING_TIME_WINDOW_SUM.

See also **assignment dimension added:** INTERVAL_AND_SUM *(assignment dimension corresponding to intervals is added)*.

common keyword: ARITH_SLIDING *(arithmetic constraint)*, INCREASING_SUM *(sum)*, PRODUCT_CTR, RANGE_CTR *(arithmetic constraint)*, SUM, SUM_CUBES_CTR, SUM_POWERS4_CTR, SUM_POWERS5_CTR, SUM_POWERS6_CTR *(sum)*, SUM_SET *(arithmetic constraint)*, SUM_SQUARES_CTR *(sum)*.

generalisation: SCALAR_PRODUCT *(arithmetic constraint where all coefficients are not necessarly equal to* 1*)*.

implied by: ARITH_SLIDING.

system of constraints: SLIDING_SUM.

Keywords **characteristic of a constraint:** sum.

constraint type: arithmetic constraint.

heuristics: regret based heuristics, regret based heuristics in matrix problems.

Cond. implications

- SUM_CTR(VARIABLES, CTR, VAR)
  with VARIABLES.var ≥ 0
  and VARIABLES.var ≤ 1
  implies SUM_SQUARES_CTR(VARIABLES, CTR, VAR)
  when VARIABLES.var ≥ 0
  and VARIABLES.var ≤ 1.

- SUM_CTR(VARIABLES, CTR, VAR)
  with VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1
  implies SUM_CUBES_CTR(VARIABLES, CTR, VAR)
  when VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1.

- SUM_CTR(VARIABLES, CTR, VAR)
  with VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1
  implies SUM_POWERS5_CTR(VARIABLES, CTR, VAR)
  when VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1.

- SUM_CTR(VARIABLES, CTR, VAR)
  with CTR $\in [=]$
  and INCREASING(VARIABLES)
  implies INCREASING_SUM(VARIABLES, VAR).

Arc input(s)	VARIABLES
Arc generator	*SELF* $\mapsto$ collection(variables)
Arc arity	1
Arc constraint(s)	TRUE
Graph property(ies)	**SUM**(VARIABLES, var) CTR VAR

Graph model Since we want to keep all the vertices of the initial graph we use the *SELF* arc generator together with the TRUE arc constraint. This predefined arc constraint always holds.

Parts (A) and (B) of Figure 5.788 respectively show the initial and final graph associated with the **Example** slot. Since we use the TRUE arc constraint both graphs are identical.

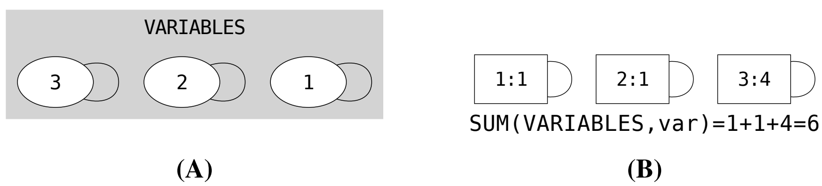


Figure 5.788: Initial and final graph of the SUM_CTR constraint

5.392 SUM_CUBES_CTR

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic constraint.

Constraint SUM_CUBES_CTR(VARIABLES, CTR, VAR)

Synonyms SUM_CUBES, SUM_OF_CUBES, SUM_OF_CUBES_CTR.

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint the sum of the cubes of a set of domain variables. More precisely, let S denote the sum of the cubes of the variables of the VARIABLES collection (when the collection is empty the corresponding sum is equal to 0). Enforce the following constraint to hold: S CTR VAR.

Example $(\langle 1, 2, 2\rangle, =, 17)$

The SUM_CUBES_CTR constraint holds since the condition $1^3 + 2^3 + 2^3 = 17$ is satisfied.

Typical

$|$VARIABLES$| > 1$
range(VARIABLES.var) > 1
CTR $\in [=, <, \geq, >, \leq]$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Contractible wrt. VARIABLES when CTR $\in [<, \leq]$ and minval(VARIABLES.var) ≥ 0.
- Contractible wrt. VARIABLES when CTR $\in [\geq, >]$ and maxval(VARIABLES.var) ≤ 0.
- Extensible wrt. VARIABLES when CTR $\in [\geq, >]$ and minval(VARIABLES.var) ≥ 0.
- Extensible wrt. VARIABLES when CTR $\in [<, \leq]$ and maxval(VARIABLES.var) ≤ 0.
- Aggregate: VARIABLES(union), CTR(id), VAR(+).

See also **common keyword:** SUM_CTR, SUM_POWERS4_CTR, SUM_POWERS5_CTR, SUM_POWERS6_CTR, SUM_SQUARES_CTR *(sum)*.

Keywords **characteristic of a constraint:** sum.

constraint type: predefined constraint, arithmetic constraint.

5.393 SUM_FREE

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin [439]

Constraint SUM_FREE(S)

Argument S : svar

Purpose Impose for all pairs of values (not necessarily distinct) i, j of the set S the fact that the sum $i + j$ is not an element of S.

Example $(\{1, 3, 5, 9\})$

The SUM_FREE$(\{1, 3, 5, 9\})$ constraint holds since:

- $1 + 1 = 2 \notin$ S, $1 + 3 = 4 \notin$ S, $1 + 5 = 6 \notin$ S, $1 + 9 = 10 \notin$ S.
- $3 + 3 = 6 \notin$ S, $3 + 5 = 8 \notin$ S, $3 + 9 = 12 \notin$ S.
- $5 + 5 = 10 \notin$ S, $5 + 9 = 14 \notin$ S.

Usage The SUM_FREE constraint was introduced by W.-J. van Hoeve and A. Sabharwal in order to model in a concise way Schur problems.

- On one hand, the first model has n domain variables x_i $(1 \leq i \leq n)$, where x_i corresponds to the subset in which element i occurs. The constraints $x_i = s \wedge x_j = s \Rightarrow x_{i+j} \neq s$ $(s \in [1, k], i, j \in [1, n], i \leq j, i + j \leq n)$ enforce that the k subsets are sum-free. We have $O(k \cdot n^2)$ such constraints.
- On the other hand, the model proposed by W.-J. van Hoeve and A. Sabharwal represents in an explicit way with a set variable S_i $(1 \leq i \leq n)$ each subset of the partition we are looking for. Now, to express the fact that these k subsets are sum-free they simply use k SUM_FREE constraints of the form SUM_FREE(S_i).

While the two models have the same behaviour when we focus on the number of backtracks the second model is much more efficient from a memory point of view.

Algorithm W.-J. van Hoeve and A. Sabharwal have proposed an algorithm that enforces bound-consistency for the SUM_FREE constraint in [439].

Keywords **constraint arguments:** unary constraint, constraint involving set variables.

constraint type: predefined constraint.

filtering: bound-consistency.

problems: Schur number.

5.394 SUM_OF_INCREMENTS

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin [95]

Constraint SUM_OF_INCREMENTS(VARIABLES, LIMIT)

Synonyms INCREMENTS_SUM, INCR_SUM, SUM_INCR, SUM_INCREMENTS.

Arguments

VARIABLES	:	collection(var−dvar)
LIMIT	:	dvar

Restrictions

required(VARIABLES, var)
VARIABLES.var ≥ 0
LIMIT ≥ 0

Purpose

Given a collection of variables VARIABLES which can only be assigned non negative values, and a variable LIMIT, enforce the condition $\texttt{VARIABLES}[1].\texttt{var} + \sum_{i=2}^{|\texttt{VARIABLES}|} \max(\texttt{VARIABLES}[i].\texttt{var} - \texttt{VARIABLES}[i-1].\texttt{var}, 0) \leq \texttt{LIMIT}$. $\texttt{VARIABLES}[1].\texttt{var}$ stands from the fact that we assume an additional implicit 0 before the first variable (i.e., $\texttt{VARIABLES}[1].\texttt{var} = \max(\texttt{VARIABLES}[1].\texttt{var} - 0, 0)$).

Example

$(\langle 4, 4, 3, 4, 6\rangle, 7)$

The SUM_OF_INCREMENTS constraint holds since we have that $4 + \max(4-4, 0) + \max(3-4, 0) + \max(4-3, 0) + \max(6-4, 0) \leq 7$.

Typical

$|\texttt{VARIABLES}| > 2$
range(VARIABLES.var) > 1
maxval(VARIABLES.var) > 0
LIMIT > 0
LIMIT $\leq$ |VARIABLES|*range(VARIABLES.var)/2

Symmetries

- One and the same constant can be added to VARIABLES.var and to LIMIT.
- Items of VARIABLES can be reversed.
- LIMIT can be increased.

Arg. properties

- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Usage The SUM_OF_INCREMENTS was initially motivated by the problem of decomposing a matrix of non-negative integers into a positive linear combination of matrices consisting of only zeros and ones, where the ones occur consecutively in each row.

Algorithm A $O(|\texttt{VARIABLES}|)$ bound-consistency filtering algorithm for the SUM_OF_INCREMENTS constraint is described in [95].

Reformulation The following reformulations are provided in [95]. Assuming $\texttt{VARIABLES}[0].\texttt{var}$ is defined as 0 (i.e., a zero is added before the first variable of the VARIABLES collection) we have:

- $\sum_{i=1}^{|\texttt{VARIABLES}|} S_i \leq \texttt{LIMIT}$ with $D_i = \texttt{VARIABLES}[i].\texttt{var} - \texttt{VARIABLES}[i-1].\texttt{var}$ and $S_i = \max(D_i, 0)$ $(1 \leq i \leq |\texttt{VARIABLES}|)$.

- $\sum_{i=1}^{|\texttt{VARIABLES}|} S_i \leq \texttt{LIMIT}$ with $\texttt{VARIABLES}[i].\texttt{var} - \texttt{VARIABLES}[i-1].\texttt{var} \leq S_i$ and $S_i \in [0, \overline{\texttt{LIMIT}}]$ $(1 \leq i \leq |\texttt{VARIABLES}|)$.

5.395 SUM_OF_WEIGHTS_OF_DISTINCT_VALUES

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [46]

Constraint SUM_OF_WEIGHTS_OF_DISTINCT_VALUES(VARIABLES, VALUES, COST)

Synonym SWDV.

Arguments

VARIABLES	:	collection(var−dvar)
VALUES	:	collection(val−int, weight−int)
COST	:	dvar

Restrictions

required(VARIABLES, var)
|VALUES| > 0
required(VALUES, [val, weight])
VALUES.weight ≥ 0
distinct(VALUES, val)
in_attr(VARIABLES, var, VALUES, val)
COST ≥ 0

Purpose

All variables of the VARIABLES collection take a value in the VALUES collection. In addition COST is the sum of the weight attributes associated with the distinct values taken by the variables of VARIABLES.

Example

$$\left(\begin{array}{l} \langle 1,6,1 \rangle, \\ \left\langle \begin{array}{ll} \mathtt{val}-1 & \mathtt{weight}-5, \\ \mathtt{val}-2 & \mathtt{weight}-3, \\ \mathtt{val}-6 & \mathtt{weight}-7 \end{array} \right\rangle, 12 \end{array} \right)$$

The SUM_OF_WEIGHTS_OF_DISTINCT_VALUES constraint holds since its last argument COST $= 12$ is equal to the sum $5 + 7$ of the weights of the values 1 and 6 that occur within the $\langle 1, 6, 1\rangle$ collection.

Typical

|VARIABLES| > 1
range(VARIABLES.var) > 1
|VALUES| > 1
range(VALUES.weight) > 1
maxval(VALUES.weight) > 0

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values of VARIABLES.var can be swapped.
- Items of VALUES are permutable.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.

Arg. properties Functional dependency: COST determined by VARIABLES and VALUES.

See also

constraint type: relaxation.

filtering: cost filtering constraint.

modelling: functional dependency.

problems: domination, weighted assignment, facilities location problem.

Arc input(s)	VARIABLES VALUES
Arc generator	$PRODUCT \mapsto$ collection(variables, values)
Arc arity	2
Arc constraint(s)	variables.var = values.val
Graph property(ies)	• **NSOURCE** = |VARIABLES| • **SUM**(VALUES, weight) = COST

Signature Since we use the $PRODUCT$ arc generator, the number of sources of the final graph cannot exceed the number of sources of the initial graph. Since the initial graph contains |VARIABLES| sources, this number is an upper bound of the number of sources of the final graph. Therefore we can rewrite **NSOURCE** = |VARIABLES| to **NSOURCE** $\geq$ |VARIABLES| and simplify $\underline{\overline{\textbf{NSOURCE}}}$ to $\overline{\textbf{NSOURCE}}$.

Parts (A) and (B) of Figure 5.789 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** graph property, the source vertices of the final graph are shown in a double circle. Since we also use the **SUM** graph property we show the vertices from which we compute the total cost in a box.

5.396 SUM_POWERS4_CTR

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin

Arithmetic constraint.

Constraint

SUM_POWERS4_CTR(VARIABLES, CTR, VAR)

Synonyms

SUM_POWERS4, SUM_OF_POWERS4, SUM_OF_POWERS4_CTR.

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose

Constraint the sum of the power of four of a set of domain variables. More precisely, let S denote the sum of the power of four of the variables of the VARIABLES collection (when the collection is empty the corresponding sum is equal to 0). Enforce the following constraint to hold: S CTR VAR.

Example

$(\langle 1, 1, 2\rangle, =, 18)$

The SUM_POWERS4_CTR constraint holds since the condition $1^4 + 1^4 + 2^4 = 18$ is satisfied.

Typical

$|$VARIABLES$| > 1$
range(VARIABLES.var) > 1
CTR $\in [=, <, \geq, >, \leq]$

Symmetry

Items of VARIABLES are permutable.

Arg. properties

- Contractible wrt. VARIABLES when CTR $\in [<, \leq]$.
- Extensible wrt. VARIABLES when CTR $\in [\geq, >]$.
- Aggregate: VARIABLES(union), CTR(id), VAR(+).

See also

common keyword: SUM_CTR, SUM_CUBES_CTR, SUM_POWERS5_CTR, SUM_POWERS6_CTR, SUM_SQUARES_CTR *(sum)*.

Keywords

characteristic of a constraint: sum.

constraint type: predefined constraint, arithmetic constraint.

5.397 SUM_POWERS5_CTR

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin Arithmetic constraint.

Constraint SUM_POWERS5_CTR(VARIABLES, CTR, VAR)

Synonyms SUM_POWERS5, SUM_OF_POWERS5, SUM_OF_POWERS5_CTR.

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint the sum of the power of five of a set of domain variables. More precisely, let S denote the sum of the power of five of the variables of the VARIABLES collection (when the collection is empty the corresponding sum is equal to 0). Enforce the following constraint to hold: S CTR VAR.

Example $(\langle 1, 1, 2\rangle, =, 34)$

The SUM_POWERS5_CTR constraint holds since the condition $1^5 + 1^5 + 2^5 = 34$ is satisfied.

Typical

|VARIABLES| > 1
range(VARIABLES.var) > 1
CTR $\in [=, <, \geq, >, \leq]$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Contractible wrt. VARIABLES when CTR $\in [<, \leq]$ and minval(VARIABLES.var) ≥ 0.
- Contractible wrt. VARIABLES when CTR $\in [\geq, >]$ and maxval(VARIABLES.var) ≤ 0.
- Extensible wrt. VARIABLES when CTR $\in [\geq, >]$ and minval(VARIABLES.var) ≥ 0.
- Extensible wrt. VARIABLES when CTR $\in [<, \leq]$ and maxval(VARIABLES.var) ≤ 0.
- Aggregate: VARIABLES(union), CTR(id), VAR(+).

5.399 SUM_SET

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin

H. Cambazard

Constraint

SUM_SET(SV, VALUES, CTR, VAR)

Arguments

SV	:	svar
VALUES	:	collection(val−int, coef−int)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VALUES, [val, coef])
distinct(VALUES, val)
VALUES.coef ≥ 0
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose

Let SUM denote the sum of the coef attributes of the VALUES collection for which the corresponding values val occur in the set SV. Enforce the following constraint to hold: SUM CTR VAR.

Example

$$\left(\begin{array}{l}\{2,3,6\}, \\ \left\langle\begin{array}{ll}\texttt{val}-2 & \texttt{coef}-7, \\ \texttt{val}-9 & \texttt{coef}-1, \\ \texttt{val}-5 & \texttt{coef}-7, \\ \texttt{val}-6 & \texttt{coef}-2\end{array}\right\rangle, =, 9\end{array}\right)$$

The SUM_SET constraint holds since the sum of the coef attributes $7 + 2$ for which the corresponding val attribute belongs to the first argument SV $= \{2, 3, 6\}$ is equal (i.e., since CTR is set to $=$) to its last argument VAR $= 9$.

Typical

$|\texttt{VALUES}| > 1$
VALUES.coef > 0
CTR $\in [=, <, \geq, >, \leq]$

Symmetry

Items of VALUES are permutable.

Systems

WEIGHTS in **Gecode**.

5.400 SUM_SQUARES_CTR

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic constraint.

Constraint SUM_SQUARES_CTR(VARIABLES, CTR, VAR)

Synonyms SUM_SQUARES, SUM_OF_SQUARES, SUM_OF_SQUARES_CTR.

Arguments

VARIABLES	:	collection(var−dvar)
CTR	:	atom
VAR	:	dvar

Restrictions

required(VARIABLES, var)
CTR $\in [=, \neq, <, \geq, >, \leq]$

Purpose Constraint the sum of the squares of a set of domain variables. More precisely, let S denote the sum of the squares of the variables of the VARIABLES collection (when the collection is empty the corresponding sum is equal to 0). Enforce the following constraint to hold: S CTR VAR.

Example $(\langle 1, 1, 4\rangle, =, 18)$

The SUM_SQUARES_CTR constraint holds since the condition $1^2 + 1^2 + 4^2 = 18$ is satisfied.

Typical

$|\texttt{VARIABLES}| > 1$
range(VARIABLES.var) > 1
CTR $\in [=, <, \geq, >, \leq]$

Symmetry Items of VARIABLES are permutable.

Arg. properties

- Contractible wrt. VARIABLES when CTR $\in [<, \leq]$.
- Extensible wrt. VARIABLES when CTR $\in [\geq, >]$.
- Aggregate: VARIABLES(union), CTR(id), VAR(+).

See also **common keyword:** SUM_CTR, SUM_CUBES_CTR, SUM_POWERS4_CTR, SUM_POWERS5_CTR, SUM_POWERS6_CTR *(sum)*.

Keywords **characteristic of a constraint:** sum.

constraint type: predefined constraint, arithmetic constraint.

Cond. implications

- SUM_SQUARES_CTR(VARIABLES, CTR, VAR)
  with VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1
  implies SUM_POWERS4_CTR(VARIABLES, CTR, VAR)
  when VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1.

- SUM_SQUARES_CTR(VARIABLES, CTR, VAR)
  with VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1
  implies SUM_POWERS6_CTR(VARIABLES, CTR, VAR)
  when VARIABLES.var ≥ -1
  and VARIABLES.var ≤ 1.

5.401 SYMMETRIC

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [151]

Constraint SYMMETRIC(NODES)

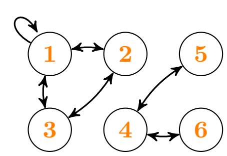
Argument NODES : collection(index−int, succ−svar)

Restrictions
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)

Purpose Consider a digraph G described by the NODES collection. Select a subset of arcs of G so that the corresponding graph is symmetric (i.e., if there is an arc from i to j, there is also an arc from j to i).

Example

$$\left(\left\langle\begin{array}{ll} \texttt{index}-1 & \texttt{succ}-\{1,2,3\}, \\ \texttt{index}-2 & \texttt{succ}-\{1,3\}, \\ \texttt{index}-3 & \texttt{succ}-\{1,2\}, \\ \texttt{index}-4 & \texttt{succ}-\{5,6\}, \\ \texttt{index}-5 & \texttt{succ}-\{4\}, \\ \texttt{index}-6 & \texttt{succ}-\{4\} \end{array}\right\rangle\right)$$



The SYMMETRIC constraint holds since the NODES collection depicts a symmetric graph.

Typical |NODES| > 2

Symmetry Items of NODES are permutable.

Algorithm The filtering algorithm for the SYMMETRIC constraint is given in [151, page 87]. It removes (respectively imposes) the arcs (i, j) for which the arc (j, i) is not present (respectively is present). It has an overall complexity of $O(n+m)$ where n and m respectively denote the number of vertices and the number of arcs of the initial graph.

See also **common keyword:** CONNECTED *(symmetric)*.

used in graph description: IN_SET.

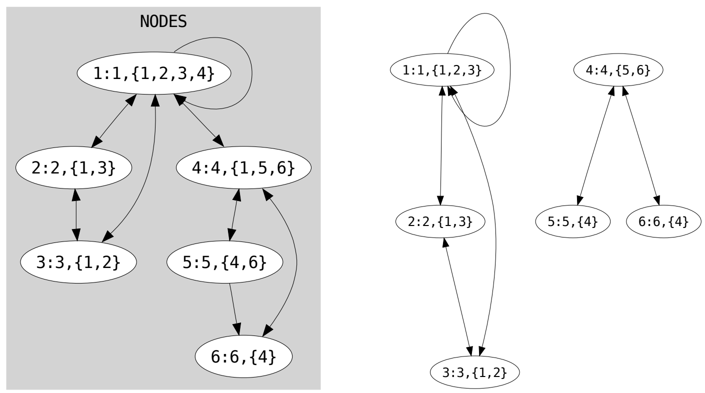
Keywords **constraint arguments:** constraint involving set variables.

constraint type: graph constraint.

final graph structure: symmetric.

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	IN_SET(nodes2.index, nodes1.succ)
Graph class	SYMMETRIC

Graph model Part (A) of Figure 5.791 shows the initial graph from which we start. It is derived from the set associated with each vertex. Each set describes the potential values of the succ attribute of a given vertex. Part (B) of Figure 5.791 gives the final graph associated with the **Example** slot.



(A) **(B)**

Figure 5.791: Initial and final graph of the SYMMETRIC set constraint

5.402 SYMMETRIC_ALLDIFFERENT

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [356]

Constraint SYMMETRIC_ALLDIFFERENT(NODES)

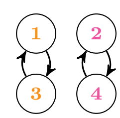
Synonyms SYMMETRIC_ALLDIFF, SYMMETRIC_ALLDISTINCT, SYMM_ALLDIFFERENT, SYMM_ALLDIFF, SYMM_ALLDISTINCT, ONE_FACTOR, TWO_CYCLE.

Argument NODES : collection(index−int, succ−dvar)

Restrictions
$|\texttt{NODES}| \bmod 2 = 0$
required(NODES, [index, succ])
$\texttt{NODES.index} \geq 1$
$\texttt{NODES.index} \leq |\texttt{NODES}|$
distinct(NODES, index)
$\texttt{NODES.succ} \geq 1$
$\texttt{NODES.succ} \leq |\texttt{NODES}|$

Purpose All variables associated with the succ attribute of the NODES collection should be pairwise distinct. In addition enforce the following condition: if variable NODES$[i]$.succ takes value j with $j \neq i$ then variable NODES$[j]$.succ takes value i. This can be interpreted as a graph-covering problem where one has to cover a digraph G with circuits of length two in such a way that each vertex of G belongs to a single circuit.

Example
$$\left(\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-3,\\ \texttt{index}-2 & \texttt{succ}-4,\\ \texttt{index}-3 & \texttt{succ}-1,\\ \texttt{index}-4 & \texttt{succ}-2\end{array}\right\rangle\right)$$



The SYMMETRIC_ALLDIFFERENT constraint holds since:

- NODES[1].succ $= 3 \Leftrightarrow$ NODES[3].succ $= 1$,
- NODES[2].succ $= 4 \Leftrightarrow$ NODES[4].succ $= 2$.

All solutions Figure 5.792 gives all solutions to the following non ground instance of the SYMMETRIC_ALLDIFFERENT constraint: $\texttt{S}_1 \in [1,4]$, $\texttt{S}_2 \in [1,3]$, $\texttt{S}_3 \in [1,4]$, $\texttt{S}_4 \in [1,3]$, SYMMETRIC_ALLDIFFERENT($\langle 1\,\texttt{S}_1, 2\,\texttt{S}_2, 3\,\texttt{S}_3, 4\,\texttt{S}_4\rangle$).

Typical $|\texttt{NODES}| \geq 4$

Symmetry Items of NODES are permutable.

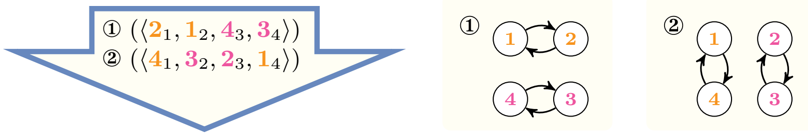


Figure 5.792: All solutions corresponding to the non ground example of the SYMMETRIC_ALLDIFFERENT constraint of the **All solutions** slot; in the left-hand side the `index` attributes are displayed as indices of the `succ` attribute, while in the right-hand side they are directly displayed within each node.

Usage As it was reported in [356, page 420], this constraint is useful to express matches between persons or between teams. The SYMMETRIC_ALLDIFFERENTconstraint also appears implicitly in the *cycle cover problem* and corresponds to the four conditions given in section 1 *Modeling the Cycle Cover Problem* of [319].

Remark This constraint is referenced under the name ONE_FACTOR in [222] as well as in [420]. From a modelling point of view this constraint can be expressed with the CYCLE constraint [47] where one imposes the additional condition that each cycle has only two nodes.

Algorithm A filtering algorithm for the SYMMETRIC_ALLDIFFERENT constraint was proposed by J.-C. Régin in [356]. It achieves arc-consistency and its running time is dominated by the complexity of finding all edges that do not belong to any maximum cardinality matching in an undirected n-vertex, m-edge graph, i.e., $O(m \cdot n)$.

For the soft case of the SYMMETRIC_ALLDIFFERENT constraint where the cost is the minimum number of variables to assign differently in order to get back to a solution, a filtering algorithm achieving arc-consistency is described in [140, 139]. It has a complexity of $O(p \cdot m)$, where p is the number of maximal extreme sets in the value graph associated with the constraint and m is the number of edges. It iterates over extreme sets and not over vertices as in the algorithm due to J.-C. Régin.

Reformulation The SYMMETRIC_ALLDIFFERENT(NODES) constraint can be expressed in term of a conjunction of $|\texttt{NODES}|^2$ reified constraints of the form $\texttt{NODES}[i].\texttt{succ} = j \Leftrightarrow \texttt{NODES}[j].\texttt{succ} = i$ $(1 \leq i, j \leq |\texttt{NODES}|)$. The SYMMETRIC_ALLDIFFERENT constraint can also be reformulated as an INVERSE constraint as shown below:

$$\text{SYMMETRIC\_ALLDIFFERENT}\left(\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-s_1,\\ \texttt{index}-2 & \texttt{succ}-s_2,\\ \vdots & \vdots\\ \texttt{index}-n & \texttt{succ}-s_n\end{array}\right\rangle\right)$$

$$\text{INVERSE}\left(\left\langle\begin{array}{lll}\texttt{index}-1 & \texttt{succ}-s_1 & \texttt{pred}-s_1,\\ \texttt{index}-2 & \texttt{succ}-s_2 & \texttt{pred}-s_2,\\ \vdots & \vdots & \vdots\\ \texttt{index}-n & \texttt{succ}-s_n & \texttt{pred}-s_n\end{array}\right\rangle\right)$$

A third reformulation using one ALLDIFFERENT constraint and n ELEMENT constraints is as follows. ALLDIFFERENT$(\langle s_1, s_2, \ldots, s_n\rangle)$, $\forall i \in [1, n] : s_i \neq i$, ELEMENT$(s_i, \langle s_1, s_2, \ldots, s_n\rangle, i)$. Figure 5.793 illustrates this third reformulation of the SYMMETRIC_ALLDIFFERENT constraint.

Cond. implications

- SYMMETRIC_ALLDIFFERENT(NODES)
  implies BALANCE_CYCLE(BALANCE, NODES)
  when BALANCE $= 0$.
- SYMMETRIC_ALLDIFFERENT(NODES)
  implies CYCLE(NCYCLE, NODES)
  when $2 *$ NCYCLE $= |$NODES$|$.
- SYMMETRIC_ALLDIFFERENT(NODES)
  implies PERMUTATION(VARIABLES : NODES).

Arc input(s)	NODES
Arc generator	$CLIQUE(\neq) \mapsto$collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	• nodes1.succ = nodes2.index • nodes2.succ = nodes1.index
Graph property(ies)	**NARC**= |NODES|

Graph model In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices.

Parts (A) and (B) of Figure 5.794 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

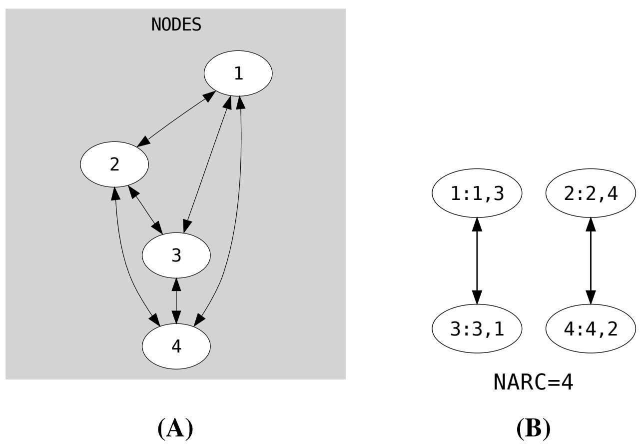

Figure 5.794: Initial and final graph of the SYMMETRIC_ALLDIFFERENT constraint

Signature Since all the index attributes of the NODES collection are distinct, and because of the first condition nodes1.succ = nodes2.index of the arc constraint, each vertex of the final graph has at most one successor. Therefore the maximum number of arcs of the final graph is equal to the maximum number of vertices |NODES| of the final graph. So we can rewrite $\mathbf{NARC}$ = |NODES| to $\mathbf{NARC} \geq$ |NODES| and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.403 SYMMETRIC_ALLDIFFERENT_EXCEPT_0

► ▷ ◁ ◄ DESCRIPTION LINKS

Origin Derived from SYMMETRIC_ALLDIFFERENT

Constraint SYMMETRIC_ALLDIFFERENT_EXCEPT_0(NODES)

Synonyms SYMMETRIC_ALLDIFF_EXCEPT_0, SYMMETRIC_ALLDISTINCT_EXCEPT_0, SYMM_ALLDIFFERENT_EXCEPT_0, SYMM_ALLDIFF_EXCEPT_0, SYMM_ALLDISTINCT_EXCEPT_0.

Argument NODES : collection(index−int, succ−dvar)

Restrictions

required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.succ ≥ 0
NODES.succ $\leq$ |NODES|

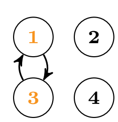
Purpose

Enforce the following three conditions:

1. $\forall i \in [1, |\texttt{NODES}|]$, $\forall j \in [1, |\texttt{NODES}|]$, $(j \neq i)$: $\texttt{NODES}[i].\texttt{succ} = 0 \vee \texttt{NODES}[j].\texttt{succ} = 0 \vee \texttt{NODES}[i].\texttt{succ} \neq \texttt{NODES}[j].\texttt{succ}$.
2. $\forall i \in [1, |\texttt{NODES}|] : \texttt{NODES}[i].\texttt{succ} \neq i$.
3. $\texttt{NODES}[i].\texttt{succ} = j \wedge j \neq i \wedge j \neq 0 \Leftrightarrow \texttt{NODES}[j].\texttt{succ} = i \wedge i \neq j \wedge i \neq 0$.

Example

$$\left(\left\langle\begin{array}{ll} \texttt{index}-1 & \texttt{succ}-3, \\ \texttt{index}-2 & \texttt{succ}-0, \\ \texttt{index}-3 & \texttt{succ}-1, \\ \texttt{index}-4 & \texttt{succ}-0 \end{array}\right\rangle\right)$$



The SYMMETRIC_ALLDIFFERENT_EXCEPT_0 constraint holds since:

- $\texttt{NODES}[1].\texttt{succ} = 3 \Leftrightarrow \texttt{NODES}[3].\texttt{succ} = 1$,
- $\texttt{NODES}[2].\texttt{succ} = 0$ and value 2 is not assigned to any variable.
- $\texttt{NODES}[4].\texttt{succ} = 0$ and value 4 is not assigned to any variable.

Given 3 successor variables that have to be assigned a value in interval $[0, 3]$, the solutions to the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 $(\langle \texttt{index}-1\ \texttt{succ}-s_1, \texttt{index}-2\ \texttt{succ}-s_2, \texttt{index}-3\ \texttt{succ}-s_3\rangle)$ constraint are $\langle 1\ 0, 2\ 0, 3\ 0\rangle$, $\langle 1\ 0, 2\ 3, 3\ 2\rangle$, $\langle 1\ 2, 2\ 1, 3\ 0\rangle$, and $\langle 1\ 3, 2\ 0, 3\ 1\rangle$.

Given 4 successor variables that have to be assigned a value in interval $[0, 3]$, the solutions to the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 $(\langle \texttt{index}-1\ \texttt{succ}-s_1, \texttt{index}-2\ \texttt{succ}-$

s_2, index $-$ 3 succ $-$ s_3, index $-$ 4 succ $-$ s_4⟩) constraint are $\langle 1\ 0, 2\ 0, 3\ 0, 4\ 0\rangle$, $\langle 1\ 0, 2\ 0, 3\ 4, 4\ 3\rangle$, $\langle 1\ 0, 2\ 3, 3\ 2, 4\ 0\rangle$, $\langle 1\ 0, 2\ 4, 3\ 0, 4\ 2\rangle$, $\langle 1\ 2, 2\ 1, 3\ 0, 4\ 0\rangle$, $\langle 1\ 2, 2\ 1, 3\ 4, 4\ 3\rangle$, $\langle 1\ 3, 2\ 0, 3\ 1, 4\ 0\rangle$, $\langle 1\ 3, 2\ 4, 3\ 1, 4\ 2\rangle$, $\langle 1\ 4, 2\ 0, 3\ 0, 4\ 1\rangle$, $\langle 1\ 4, 2\ 3, 3\ 2, 4\ 1\rangle$.

All solutions

Figure 5.795 gives all solutions to the following non ground instance of the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 constraint: $\mathtt{S}_1 \in [0,5]$, $\mathtt{S}_2 \in [1,3]$, $\mathtt{S}_3 \in [1,4]$, $\mathtt{S}_4 \in [0,3]$, $\mathtt{S}_5 \in [0,2]$, SYMMETRIC_ALLDIFFERENT_EXCEPT_0($\langle 1\ \mathtt{S}_1, 2\ \mathtt{S}_2, 3\ \mathtt{S}_3, 4\ \mathtt{S}_4, 5\ \mathtt{S}_5\rangle$).

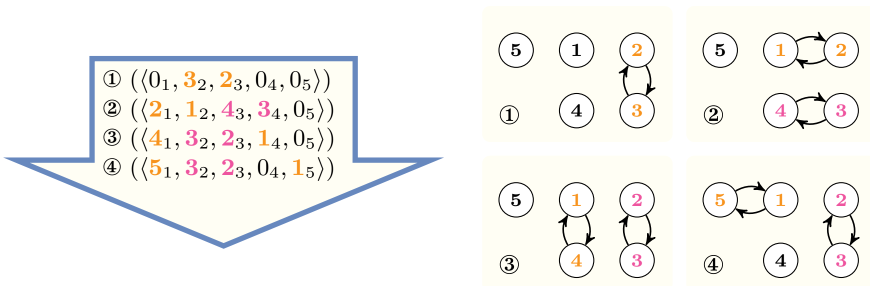


Figure 5.795: All solutions corresponding to the non ground example of the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 constraint of the **All solutions** slot; in the left-hand side the index attributes are displayed as indices of the succ attribute, while in the right-hand side they are directly displayed within each node.

Typical

$|\mathtt{NODES}| \geq 4$
minval(NODES.succ) $= 0$
maxval(NODES.succ) > 0

Symmetry

Items of NODES are permutable.

Usage

Within the context of sport scheduling, NODES$[i]$.succ $= j$ (with $i, j \in [1, |\mathtt{NODES}|]$, $i \neq j$) is interpreted as the fact that team i plays against team j, while NODES$[i]$.succ $= 0$ (with $i \in [1, |\mathtt{NODES}|]$) is interpreted as the fact that team i does not play at all.

Algorithm

An arc-consistency filtering algorithm for the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 constraint is described in [140, 139]. The algorithm is based on the following facts:

- First, one can map solutions to the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 constraint to perfect (g, f)-matchings in a non-bipartite graph derived from the domain of the variables of the constraint where $g(x) = 0$, $f(x) = 1$ for vertices x which have 0 in their domains, and $g(x) = f(x) = 1$ for all the remaining vertices. A *perfect* (g, f)*-matching* $\mathcal{M}$ of a graph is a subset of edges such that every vertex x is incident with the number of edges in $\mathcal{M}$ between $g(x)$ and $f(x)$.
- Second, Gallai-Edmonds decomposition [190, 159] allows us to find out all edges that do not belong to any perfect (g, f)-matchings, and therefore prune the corresponding variables.

Reformulation Let n denotes the number nodes of the NODES collection, and let s_i (with $i \in [1, n]$) denotes NODES$[i]$.succ. The SYMMETRIC_ALLDIFFERENT_EXCEPT_0(NODES) constraint can be expressed in term of a conjunction of one ALLDIFFERENT_EXCEPT_0 constraint and n ELEMENT constraints as follows. ALLDIFFERENT_EXCEPT_0$(\langle s_1, s_2, \ldots, s_n\rangle)$, $\forall i \in [1, n] : s_i \neq i$, $t_i = s_i + 1$, ELEMENT$(t_i, \langle i, s_1, s_2, \ldots, s_n\rangle, i)$. Note the introduction of the intermediate variables t_i (with $i \in [1, n]$) motivated by the need to have an index starting at 1 rather than 0 in the ELEMENT constraint. Figure 5.796 illustrates this reformulation of the SYMMETRIC_ALLDIFFERENT_EXCEPT_0 constraint.

5.404 SYMMETRIC_ALLDIFFERENT_LOOP

DESCRIPTION LINKS GRAPH

Origin

Derived from SYMMETRIC_ALLDIFFERENT

Constraint

SYMMETRIC_ALLDIFFERENT_LOOP(NODES)

Synonyms

SYMMETRIC_ALLDIFF_LOOP, SYMMETRIC_ALLDISTINCT_LOOP, SYMM_ALLDIFFERENT_LOOP, SYMM_ALLDIFF_LOOP, SYMM_ALLDISTINCT_LOOP.

Argument

NODES : collection(index−int, succ−dvar)

Restrictions

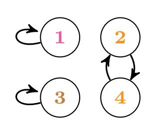
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ $\leq$ |NODES|

Purpose

All variables associated with the succ attribute of the NODES collection should be pairwise distinct. In addition enforce the following condition: if variable NODES$[i]$.succ is assigned value j then variable NODES$[j]$.succ is assigned value i. Note that i and j are not necessarily distinct. This can be interpreted as a graph-covering problem where one has to cover a digraph G with circuits of length two or one in such a way that each vertex of G belongs to a single circuit.

Example

$$\left(\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-1,\\ \texttt{index}-2 & \texttt{succ}-4,\\ \texttt{index}-3 & \texttt{succ}-3,\\ \texttt{index}-4 & \texttt{succ}-2\end{array}\right\rangle\right)$$



The SYMMETRIC_ALLDIFFERENT_LOOP constraint holds since:

- We have two loops respectively corresponding to NODES[1].succ $=$ 1 and NODES[3].succ $= 3$.
- We have one circuit of length 2 corresponding to NODES[2].succ $= 4 \Leftrightarrow$ NODES[4].succ $= 2$.

Figure 5.797 provides a second example involving a SYMMETRIC_ALLDIFFERENT_LOOP constraint.

All solutions

Figure 5.798 gives all solutions to the following non ground instance of the SYMMETRIC_ALLDIFFERENT_LOOP constraint: $\mathtt{S}_1 \in [2,5]$, $\mathtt{S}_2 \in [1,3]$, $\mathtt{S}_3 \in [1,4]$, $\mathtt{S}_4 \in [2,4]$, $\mathtt{S}_5 \in [1,5]$, SYMMETRIC_ALLDIFFERENT_LOOP($\langle 1\ \mathtt{S}_1, 2\ \mathtt{S}_2, 3\ \mathtt{S}_3, 4\ \mathtt{S}_4, 5\ \mathtt{S}_5\rangle$).

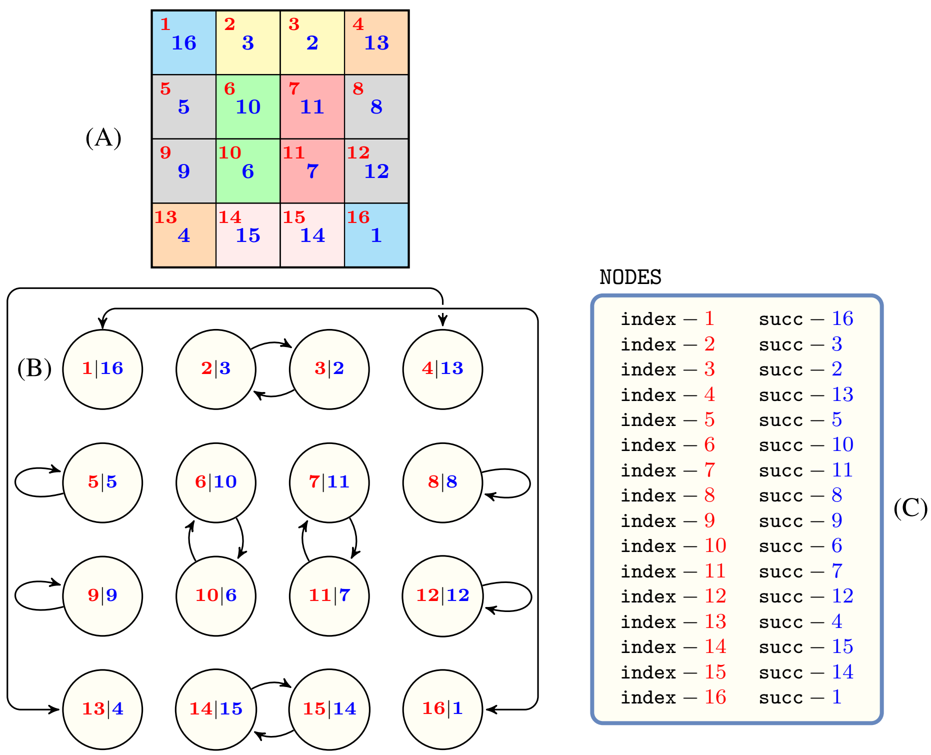


Figure 5.797: (A) Magic square Duerer where cells that belong to a same cycle are coloured identically by a colour different from grey; each cell has an *index* in its upper left corner (in red) and a *value* (in blue). (B) Corresponding graph where there is an arc from node i to node j if and only if the value of cell i is equal to the index of cell j. (C) Collection of nodes passed to the SYMMETRIC_ALLDIFFERENT_LOOP constraint: the four self-loops of the graph correspond to the four grey cells of the magic square such that the value of the cell (in blue) is equal to the index of the cell (in red).

Typical $|\mathtt{NODES}| \geq 4$

Symmetry Items of NODES are permutable.

Algorithm An arc-consistency filtering algorithm for the SYMMETRIC_ALLDIFFERENT_LOOP constraint is described in [140, 139]. The algorithm is based on the following ideas:

- First, one can map solutions to the SYMMETRIC_ALLDIFFERENT_LOOP constraint to perfect (g, f)-matchings in a non-bipartite graph derived from the domain of the variables of the constraint where $g(x) = 0$, $f(x) = 1$ for vertices x which have a self-loop, and $g(x) = f(x) = 1$ for all the remaining vertices. A *perfect* (g, f)-*matching* $\mathcal{M}$ of a graph is a subset of edges such that every vertex x is incident with the number of edges in $\mathcal{M}$ between $g(x)$ and $f(x)$.

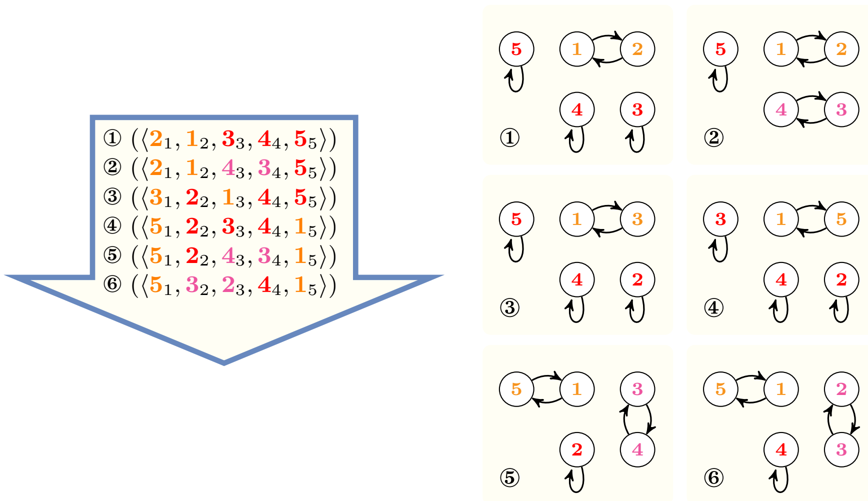

Figure 5.798: All solutions corresponding to the non ground example of the SYMMETRIC_ALLDIFFERENT_LOOP constraint of the **All solutions** slot; in the left-hand side the `index` attributes are displayed as indices of the `succ` attribute and self loops are coloured in red, while in the right-hand side the `index` attributes are directly displayed within each node.

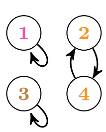
- Second, Gallai-Edmonds decomposition [190, 159] allows us to find out all edges that do not belong any perfect (g, f)-matchings, and therefore prune the corresponding variables.

Reformulation

Let n denotes the number nodes of the `NODES` collection, and let s_i (with $i \in [1, n]$) denotes `NODES`$[i]$`.succ`. The SYMMETRIC_ALLDIFFERENT_LOOP(`NODES`) constraint can be expressed in term of a conjunction of one ALLDIFFERENT constraint and n ELEMENT constraints. ALLDIFFERENT$(\langle s_1, s_2, \ldots, s_n\rangle)$, $\forall i \in [1, n]$: ELEMENT$(s_i, \langle s_1, s_2, \ldots, s_n\rangle, i)$. Figure 5.799 illustrates this reformulation of the SYMMETRIC_ALLDIFFERENT_LOOP constraint.

(A)



(B)

ALLDIFFERENT$(\langle 1, 4, 3, 2\rangle)$	*two vertices do not point to the same vertex*
ELEMENT$(1, \langle 1, 4, 3, 2\rangle, 1)$	*successor of vertex 1 is vertex 1, a self-loop*
ELEMENT$(4, \langle 1, 4, 3, 2\rangle, 2)$	*successor of vertex 2, vertex 4, goes back to 2*
ELEMENT$(3, \langle 1, 4, 3, 2\rangle, 3)$	*successor of vertex 3 is vertex 3, a self-loop*
ELEMENT$(2, \langle 1, 4, 3, 2\rangle, 4)$	*successor of vertex 4, vertex 2, goes back to 4*

Figure 5.799: Illustrating the reformulation of the SYMMETRIC_ALLDIFFERENT_LOOP$(\langle 1\ 1, 2\ 4, 3\ 3, 4\ 2\rangle)$ constraint with a set of ELEMENT constraints: (A) the figure of the **Example** slot, and (B) the corresponding constraints

Counting

See also

implied by: SYMMETRIC_ALLDIFFERENT.

implies: TWIN.

implies (items to collection): LEX_ALLDIFFERENT.

Keywords

characteristic of a constraint: all different, disequality.

combinatorial object: permutation, involution, matching.

constraint type: graph constraint, graph partitioning constraint.

final graph structure: circuit.

modelling: cycle.

Cond. implications

SYMMETRIC_ALLDIFFERENT_LOOP(NODES)
implies PERMUTATION(VARIABLES : NODES).

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	• nodes1.succ = nodes2.index • nodes2.succ = nodes1.index
Graph property(ies)	$\mathbf{NARC} = \vert\mathtt{NODES}\vert$

Graph model In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices.

Parts (A) and (B) of Figure 5.800 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

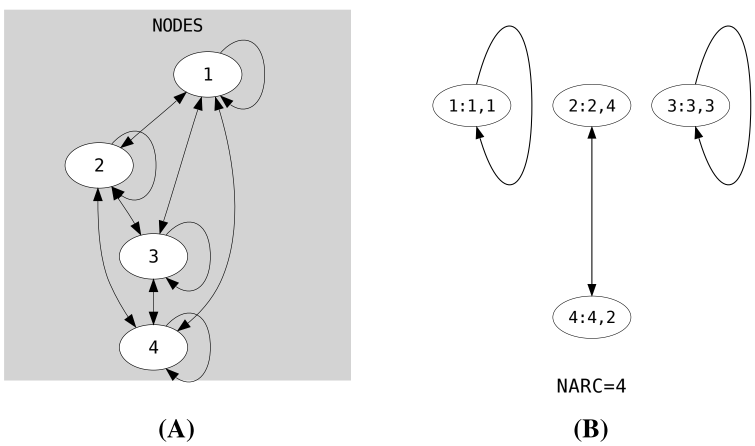

Figure 5.800: Initial and final graph of the SYMMETRIC_ALLDIFFERENT_LOOP constraint

Signature Since all the index attributes of the NODES collection are distinct, and because of the first condition nodes1.succ = nodes2.index of the arc constraint, each vertex of the final graph has at most one successor. Therefore the maximum number of arcs of the final graph is equal to the maximum number of vertices |NODES| of the final graph. So we can rewrite $\mathbf{NARC} = |\mathtt{NODES}|$ to $\mathbf{NARC} \geq |\mathtt{NODES}|$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.405 SYMMETRIC_CARDINALITY

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from GLOBAL_CARDINALITY by W. Kocjan.

Constraint SYMMETRIC_CARDINALITY(VARS, VALS)

Arguments

$$\begin{array}{lll}\texttt{VARS} & : & \texttt{collection}(\texttt{idvar}-\texttt{int}, \texttt{var}-\texttt{svar}, \texttt{l}-\texttt{int}, \texttt{u}-\texttt{int}) \\ \texttt{VALS} & : & \texttt{collection}(\texttt{idval}-\texttt{int}, \texttt{val}-\texttt{svar}, \texttt{l}-\texttt{int}, \texttt{u}-\texttt{int})\end{array}$$

Restrictions

$\texttt{required}(\texttt{VARS}, [\texttt{idvar}, \texttt{var}, \texttt{l}, \texttt{u}])$
$|\texttt{VARS}| \geq 1$
$\texttt{VARS.idvar} \geq 1$
$\texttt{VARS.idvar} \leq |\texttt{VARS}|$
$\texttt{distinct}(\texttt{VARS}, \texttt{idvar})$
$\texttt{VARS.l} \geq 0$
$\texttt{VARS.l} \leq \texttt{VARS.u}$
$\texttt{VARS.u} \leq |\texttt{VALS}|$
$\texttt{required}(\texttt{VALS}, [\texttt{idval}, \texttt{val}, \texttt{l}, \texttt{u}])$
$|\texttt{VALS}| \geq 1$
$\texttt{VALS.idval} \geq 1$
$\texttt{VALS.idval} \leq |\texttt{VALS}|$
$\texttt{distinct}(\texttt{VALS}, \texttt{idval})$
$\texttt{VALS.l} \geq 0$
$\texttt{VALS.l} \leq \texttt{VALS.u}$
$\texttt{VALS.u} \leq |\texttt{VARS}|$

Purpose Put in relation two sets: for each element of one set gives the corresponding elements of the other set to which it is associated. In addition, it constraints the number of elements associated with each element to be in a given interval.

Example

$$\left(\begin{array}{l}\left\langle\begin{array}{llll}\texttt{idvar}-1 & \texttt{var}-\{3\} & \texttt{l}-0 & \texttt{u}-1, \\ \texttt{idvar}-2 & \texttt{var}-\{1\} & \texttt{l}-1 & \texttt{u}-2, \\ \texttt{idvar}-3 & \texttt{var}-\{1,2\} & \texttt{l}-1 & \texttt{u}-2, \\ \texttt{idvar}-4 & \texttt{var}-\{1,3\} & \texttt{l}-2 & \texttt{u}-3\end{array}\right\rangle, \\ \left\langle\begin{array}{llll}\texttt{idval}-1 & \texttt{val}-\{2,3,4\} & \texttt{l}-3 & \texttt{u}-4, \\ \texttt{idval}-2 & \texttt{val}-\{3\} & \texttt{l}-1 & \texttt{u}-1, \\ \texttt{idval}-3 & \texttt{val}-\{1,4\} & \texttt{l}-1 & \texttt{u}-2, \\ \texttt{idval}-4 & \texttt{val}-\emptyset & \texttt{l}-0 & \texttt{u}-1\end{array}\right\rangle\end{array}\right)$$

The SYMMETRIC_CARDINALITY constraint holds since:

- $3 \in \texttt{VARS}[1].\texttt{var} \Leftrightarrow 1 \in \texttt{VALS}[3].\texttt{val}$,
- $1 \in \texttt{VARS}[2].\texttt{var} \Leftrightarrow 2 \in \texttt{VALS}[1].\texttt{val}$,
- $1 \in \texttt{VARS}[3].\texttt{var} \Leftrightarrow 3 \in \texttt{VALS}[1].\texttt{val}$,

- $2 \in$ VARS[3].var $\Leftrightarrow 3 \in$ VALS[2].val,
- $1 \in$ VARS[4].var $\Leftrightarrow 4 \in$ VALS[1].val,
- $3 \in$ VARS[4].var $\Leftrightarrow 4 \in$ VALS[3].val,
- The number of elements of VARS[1].var $= \{3\}$ belongs to interval $[0, 1]$,
- The number of elements of VARS[2].var $= \{1\}$ belongs to interval $[1, 2]$,
- The number of elements of VARS[3].var $= \{1, 2\}$ belongs to interval $[1, 2]$,
- The number of elements of VARS[4].var $= \{1, 3\}$ belongs to interval $[2, 3]$,
- The number of elements of VALS[1].val $= \{2, 3, 4\}$ belongs to interval $[3, 4]$,
- The number of elements of VALS[2].val $= \{3\}$ belongs to interval $[1, 1]$,
- The number of elements of VALS[3].val $= \{1, 4\}$ belongs to interval $[1, 2]$,
- The number of elements of VALS[4].val $= \emptyset$ belongs to interval $[0, 1]$.

Typical

|VARS| > 1
|VALS| > 1

Symmetries

- Items of VARS are permutable.
- Items of VALS are permutable.

Usage

The most simple example of applying SYMMETRIC_GCC is a variant of personnel assignment problem, where one person can be assigned to perform between n and m $(n \leq m)$ jobs, and every job requires between p and q $(p \leq q)$ persons. In addition every job requires different kind of skills. The previous problem can be modelled as follows:

- For each person we create an item of the VARS collection,
- For each job we create an item of the VALS collection,
- There is an arc between a person and the particular job if this person is qualified to perform it.

Remark

The SYMMETRIC_GCC constraint generalises the GLOBAL_CARDINALITY constraint by allowing a variable to take more than one value.

Algorithm

A first flow-based arc-consistency algorithm for the SYMMETRIC_CARDINALITY constraint is described in [252]. A second arc-consistency filtering algorithm exploiting matching theory [157] is described in [138, 139].

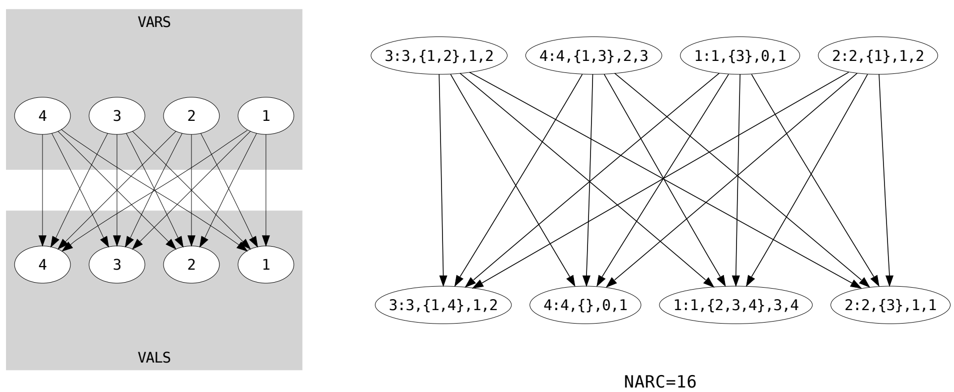
Arc constraint(s)	• IN_SET(vars.idvar, vals.val) $\Leftrightarrow$ IN_SET(vals.idval, vars.var) • vars.l $\leq$ card_set(vars.var) • vars.u $\geq$ card_set(vars.var) • vals.l $\leq$ card_set(vals.val) • vals.u $\geq$ card_set(vals.val)
Graph property(ies)	**NARC** $= \|$VARS$\| * \|$VALS$\|$

Graph model The graph model used for the SYMMETRIC_CARDINALITY is similar to the one used in the DOMAIN_CONSTRAINT or in the LINK_SET_TO_BOOLEANS constraints: we use an equivalence in the arc constraint and ask all arc constraints to hold.

Parts (A) and (B) of Figure 5.801 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, all the arcs of the final graph are stressed in bold.



(A) **(B)**

Figure 5.801: Initial and final graph of the SYMMETRIC_CARDINALITY constraint

Signature Since we use the $PRODUCT$ arc generator on the collections VARS and VALS, the number of arcs of the initial graph is equal to $|$VARS$| \cdot |$VALS$|$. Therefore the maximum number of arcs of the final graph is also equal to $|$VARS$| \cdot |$VALS$|$ and we can rewrite $\mathbf{NARC} = |$VARS$| \cdot |$VALS$|$ to $\mathbf{NARC} \geq |$VARS$| \cdot |$VALS$|$. So we can simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.406 SYMMETRIC_GCC

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from GLOBAL_CARDINALITY by W. Kocjan.

Constraint SYMMETRIC_GCC(VARS, VALS)

Synonym SGCC.

Arguments

$$\begin{array}{lll} \mathtt{VARS} & : & \mathtt{collection}(\mathtt{idvar}-\mathtt{int}, \mathtt{var}-\mathtt{svar}, \mathtt{nocc}-\mathtt{dvar}) \\ \mathtt{VALS} & : & \mathtt{collection}(\mathtt{idval}-\mathtt{int}, \mathtt{val}-\mathtt{svar}, \mathtt{nocc}-\mathtt{dvar}) \end{array}$$

Restrictions

$\mathtt{required}(\mathtt{VARS}, [\mathtt{idvar}, \mathtt{var}, \mathtt{nocc}])$
$|\mathtt{VARS}| \geq 1$
$\mathtt{VARS.idvar} \geq 1$
$\mathtt{VARS.idvar} \leq |\mathtt{VARS}|$
$\mathtt{distinct}(\mathtt{VARS}, \mathtt{idvar})$
$\mathtt{VARS.nocc} \geq 0$
$\mathtt{VARS.nocc} \leq |\mathtt{VALS}|$
$\mathtt{required}(\mathtt{VALS}, [\mathtt{idval}, \mathtt{val}, \mathtt{nocc}])$
$|\mathtt{VALS}| \geq 1$
$\mathtt{VALS.idval} \geq 1$
$\mathtt{VALS.idval} \leq |\mathtt{VALS}|$
$\mathtt{distinct}(\mathtt{VALS}, \mathtt{idval})$
$\mathtt{VALS.nocc} \geq 0$
$\mathtt{VALS.nocc} \leq |\mathtt{VARS}|$

Purpose Put in relation two sets: for each element of one set gives the corresponding elements of the other set to which it is associated. In addition, enforce a cardinality constraint on the number of occurrences of each value.

Example

$$\left(\begin{array}{l} \left\langle\begin{array}{lll} \mathtt{idvar}-1 & \mathtt{var}-\{3\} & \mathtt{nocc}-1, \\ \mathtt{idvar}-2 & \mathtt{var}-\{1\} & \mathtt{nocc}-1, \\ \mathtt{idvar}-3 & \mathtt{var}-\{1,2\} & \mathtt{nocc}-2, \\ \mathtt{idvar}-4 & \mathtt{var}-\{1,3\} & \mathtt{nocc}-2 \end{array}\right\rangle, \\ \left\langle\begin{array}{lll} \mathtt{idval}-1 & \mathtt{val}-\{2,3,4\} & \mathtt{nocc}-3, \\ \mathtt{idval}-2 & \mathtt{val}-\{3\} & \mathtt{nocc}-1, \\ \mathtt{idval}-3 & \mathtt{val}-\{1,4\} & \mathtt{nocc}-2, \\ \mathtt{idval}-4 & \mathtt{val}-\emptyset & \mathtt{nocc}-0 \end{array}\right\rangle \end{array}\right)$$

The SYMMETRIC_GCC constraint holds since:

- $3 \in \mathtt{VARS}[1].\mathtt{var} \Leftrightarrow 1 \in \mathtt{VALS}[3].\mathtt{val}$,
- $1 \in \mathtt{VARS}[2].\mathtt{var} \Leftrightarrow 2 \in \mathtt{VALS}[1].\mathtt{val}$,
- $1 \in \mathtt{VARS}[3].\mathtt{var} \Leftrightarrow 3 \in \mathtt{VALS}[1].\mathtt{val}$,

- $2 \in$ VARS[3].var $\Leftrightarrow 3 \in$ VALS[2].val,
- $1 \in$ VARS[4].var $\Leftrightarrow 4 \in$ VALS[1].val,
- $3 \in$ VARS[4].var $\Leftrightarrow 4 \in$ VALS[3].val,
- The number of elements of VARS[1].var $= \{3\}$ is equal to 1,
- The number of elements of VARS[2].var $= \{1\}$ is equal to 1,
- The number of elements of VARS[3].var $= \{1, 2\}$ is equal to 2,
- The number of elements of VARS[4].var $= \{1, 3\}$ is equal to 2,
- The number of elements of VALS[1].val $= \{2, 3, 4\}$ is equal to 3,
- The number of elements of VALS[2].val $= \{3\}$ is equal to 1,
- The number of elements of VALS[3].val $= \{1, 4\}$ is equal to 2,
- The number of elements of VALS[4].val $= \emptyset$ is equal to 0.

Typical

|VARS| > 1
|VALS| > 1

Symmetries

- Items of VARS are permutable.
- Items of VALS are permutable.

Usage

The most simple example of applying SYMMETRIC_GCC is a variant of personnel assignment problem, where one person can be assigned to perform between n and m $(n \leq m)$ jobs, and every job requires between p and q $(p \leq q)$ persons. In addition every job requires different kind of skills. The previous problem can be modelled as follows:

- For each person we create an item of the VARS collection,
- For each job we create an item of the VALS collection,
- There is an arc between a person and the particular job if this person is qualified to perform it.

Remark

The SYMMETRIC_GCC constraint generalises the GLOBAL_CARDINALITY constraint by allowing a variable to take more than one value. It corresponds to a variant of the SYMMETRIC_CARDINALITY constraint described in [252] where the occurrence variables of the VARS and VALS collections are replaced by fixed intervals.

Arc input(s)	VARS VALS
Arc generator	$PRODUCT$ $\mapsto$ collection(vars, vals)
Arc arity	2
Arc constraint(s)	• IN_SET(vars.idvar, vals.val) $\Leftrightarrow$ IN_SET(vals.idval, vars.var) • vars.nocc = card_set(vars.var) • vals.nocc = card_set(vals.val)
Graph property(ies)	**NARC** = |VARS| $*$ |VALS|

Graph model The graph model used for the SYMMETRIC_GCC is similar to the one used in the DOMAIN_CONSTRAINT or in the LINK_SET_TO_BOOLEANS constraints: we use an equivalence in the arc constraint and ask all arc constraints to hold.

Parts (A) and (B) of Figure 5.802 respectively show the initial and final graph. Since we use the **NARC** graph property, all the arcs of the final graph are stressed in bold.

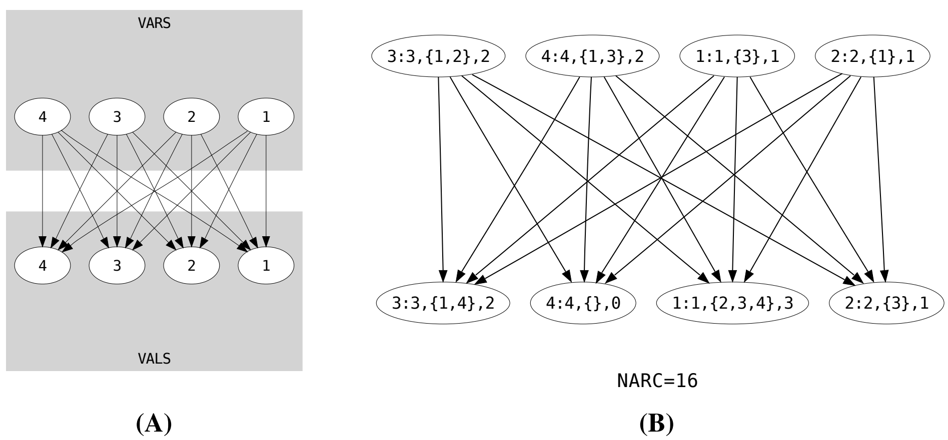

Figure 5.802: Initial and final graph of the SYMMETRIC_GCC constraint

Signature Since we use the $PRODUCT$ arc generator on the collections VARS and VALS, the number of arcs of the initial graph is equal to $|\mathtt{VARS}| \cdot |\mathtt{VALS}|$. Therefore the maximum number of arcs of the final graph is also equal to $|\mathtt{VARS}| \cdot |\mathtt{VALS}|$ and we can rewrite $\mathbf{NARC} = |\mathtt{VARS}| \cdot |\mathtt{VALS}|$ to $\mathbf{NARC} \geq |\mathtt{VARS}| \cdot |\mathtt{VALS}|$. So we can simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

5.407 TASKS_INTERSECTION

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin

Inspired by video summarization.

Constraint

TASKS_INTERSECTION(INTERSECTION, TASKS1, TASKS2)

Synonyms

INTERSECTION_BETWEEN_SEQUENCES_OF_TASKS, INTERSECTION_BETWEEN_INTERVALS, INTERSECTION_BETWEEN_TASKS_CHAINS.

Arguments

INTERSECTION	:	dvar
TASKS1	:	collection(origin−dvar, duration−dvar, end−dvar)
TASKS2	:	collection(origin−dvar, duration−dvar, end−dvar)

Restrictions

INTERSECTION ≥ 0
require_at_least(2, TASKS1, [origin, duration, end])
require_at_least(2, TASKS2, [origin, duration, end])
TASKS1.duration ≥ 0
TASKS2.duration ≥ 0
TASKS1.origin $\leq$ TASKS1.end
TASKS2.origin $\leq$ TASKS2.end
INTERSECTION $\leq$sum(TASKS1.duration)
INTERSECTION $\leq$sum(TASKS2.duration)

Purpose

INTERSECTION is the intersection between two collections of ordered tasks TASKS1 and TASKS2:

1. $\forall s \in [1, |\texttt{TASKS1}|] : \texttt{TASKS1}[s].\texttt{end} = \texttt{TASKS1}[s].\texttt{origin} + \texttt{TASKS1}[s].\texttt{duration}$,
2. $\forall t \in [1, |\texttt{TASKS2}|] : \texttt{TASKS2}[t].\texttt{end} = \texttt{TASKS2}[t].\texttt{origin} + \texttt{TASKS2}[t].\texttt{duration}$,
3. $\forall s \in [1, |\texttt{TASKS1}| - 1] : \texttt{TASKS1}[s].\texttt{end} \leq \texttt{TASKS1}[s+1].\texttt{origin}$,
4. $\forall t \in [1, |\texttt{TASKS2}| - 1] : \texttt{TASKS2}[t].\texttt{end} \leq \texttt{TASKS2}[t+1].\texttt{origin}$,
5. $\texttt{INTERSECTION} = \sum_{\substack{s \in [1,|\texttt{TASKS1}|] \\ t \in [1,|\texttt{TASKS2}|]}} \max(\beta_{s,t} - \alpha_{s,t}, 0)$ with

$$\alpha_{s,t} = \max\begin{pmatrix} \texttt{TASKS1}[s].\texttt{origin}, \\ \texttt{TASKS2}[t].\texttt{origin} \end{pmatrix}, \quad \beta_{s,t} = \min\begin{pmatrix} \texttt{TASKS1}[s].\texttt{end}, \\ \texttt{TASKS2}[t].\texttt{end} \end{pmatrix}.$$

Example

$$\left(\begin{array}{l} 3, \left\langle \begin{array}{lll} \texttt{origin}-2 & \texttt{duration}-2 & \texttt{end}-4, \\ \texttt{origin}-7 & \texttt{duration}-2 & \texttt{end}-9, \\ \texttt{origin}-9 & \texttt{duration}-0 & \texttt{end}-9 \end{array} \right\rangle, \\ \left\langle \begin{array}{lll} \texttt{origin}-1 & \texttt{duration}-3 & \texttt{end}-4, \\ \texttt{origin}-5 & \texttt{duration}-1 & \texttt{end}-6, \\ \texttt{origin}-8 & \texttt{duration}-2 & \texttt{end}-10 \end{array} \right\rangle \end{array}\right)$$

As illustrated by Figure 5.803, the constraint holds since:

- The first task of TASKS1 is included within the first task of TASKS2 and therefore contributes from its total duration 2 to the overall intersection.
- While the second task of TASKS1 does not intersect the first and second tasks of TASKS2, it has a non empty intersection of 1 with the third task of TASKS2.
- The third task of TASKS1 does not contribute to the overall intersection since its duration is equal to zero.

The overall intersection 3 is equal to $2 + 1 + 0$.

TASKS1

①	o − 2	d − 2	e − 4
②	o − 7	d − 2	e − 9
③	o − 9	d − 0	e − 9

(o for origin, d for duration, e for end)

TASKS2

(a)	o − 1	d − 3	e − 4
(b)	o − 5	d − 1	e − 6
(c)	o − 8	d − 2	e − 10

(o for origin, d for duration, e for end)

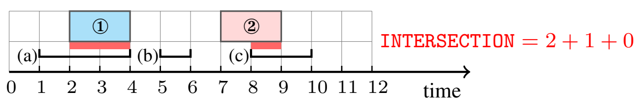

Figure 5.803: The TASKS_INTERSECTION solution to the **Example** slot

All solutions Figure 5.804 gives all solutions to the following non ground instance of the TASKS_INTERSECTION constraint: $\mathtt{O}_1 \in [0,1]$, $\mathtt{D}_1 \in [0,6]$, $\mathtt{E}_1 \in [3,5]$, $\mathtt{O}_2 \in [0,6]$, $\mathtt{D}_2 \in [1,3]$, $\mathtt{E}_2 \in [0,9]$, TASKS_INTERSECTION(**2**, $\langle \mathtt{O}_1\ \mathtt{D}_1\ \mathtt{E}_1,\ \mathtt{O}_2\ \mathtt{D}_2\ \mathtt{E}_2\rangle$, $\langle$**1 3 4**, **5 1 6**, **8 2 10**$\rangle$).

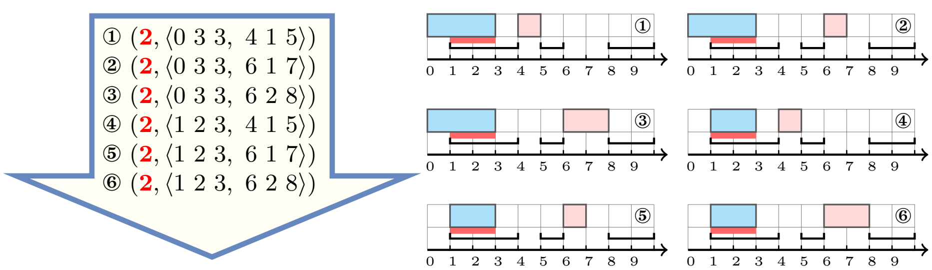

Figure 5.804: All solutions corresponding to the non ground example of the TASKS_INTERSECTION constraint of the **All solutions** slot

Typical

$\mathtt{INTERSECTION} > 0$
$|\mathtt{TASKS1}| > 1$
$|\mathtt{TASKS2}| > 1$
range(TASKS1.duration) > 1
range(TASKS2.duration) > 1

Arg. properties Functional dependency: INTERSECTION determined by TASKS1 and TASKS2.

Keywords

constraint type: predefined constraint, scheduling constraint.

filtering: minimum task duration.

modelling: zero-duration task.

5.408 TEMPORAL_PATH

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin ILOG

Constraint TEMPORAL_PATH(NPATH, NODES)

Arguments

$$\begin{array}{lll} \texttt{NPATH} & : & \texttt{dvar} \\ \texttt{NODES} & : & \texttt{collection}\left(\begin{array}{l} \texttt{index}-\texttt{int}, \\ \texttt{succ}-\texttt{dvar}, \\ \texttt{start}-\texttt{dvar}, \\ \texttt{end}-\texttt{dvar} \end{array}\right) \end{array}$$

Restrictions

$\texttt{NPATH} \geq 1$
$\texttt{NPATH} \leq |\texttt{NODES}|$
$\texttt{required}(\texttt{NODES}, [\texttt{index}, \texttt{succ}, \texttt{start}, \texttt{end}])$
$|\texttt{NODES}| > 0$
$\texttt{NODES.index} \geq 1$
$\texttt{NODES.index} \leq |\texttt{NODES}|$
$\texttt{distinct}(\texttt{NODES}, \texttt{index})$
$\texttt{NODES.succ} \geq 1$
$\texttt{NODES.succ} \leq |\texttt{NODES}|$
$\texttt{NODES.start} \leq \texttt{NODES.end}$

Purpose

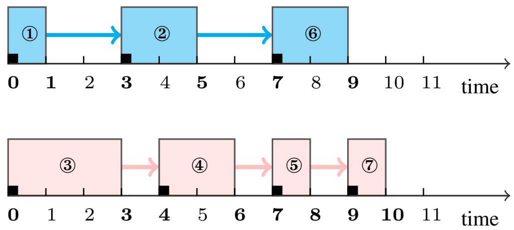
Let G be the digraph described by the NODES collection. Partition G with a set of disjoint paths such that each vertex of the graph belongs to a single path. In addition, for all pairs of consecutive vertices of a path we have a precedence constraint that enforces the end associated with the first vertex to be less than or equal to the start related to the second vertex.

Example

$$\left(2, \left\langle \begin{array}{llll} \texttt{index}-1 & \texttt{succ}-2 & \texttt{start}-0 & \texttt{end}-1, \\ \texttt{index}-2 & \texttt{succ}-6 & \texttt{start}-3 & \texttt{end}-5, \\ \texttt{index}-3 & \texttt{succ}-4 & \texttt{start}-0 & \texttt{end}-3, \\ \texttt{index}-4 & \texttt{succ}-5 & \texttt{start}-4 & \texttt{end}-6, \\ \texttt{index}-5 & \texttt{succ}-7 & \texttt{start}-7 & \texttt{end}-8, \\ \texttt{index}-6 & \texttt{succ}-6 & \texttt{start}-7 & \texttt{end}-9, \\ \texttt{index}-7 & \texttt{succ}-7 & \texttt{start}-9 & \texttt{end}-10 \end{array} \right\rangle \right)$$

The TEMPORAL_PATH constraint holds since:

- The items of the NODES collection represent the two (NPATH $= 2$) paths $1 \rightarrow 2 \rightarrow 6$ and $3 \rightarrow 4 \rightarrow 5 \rightarrow 7$.
- As illustrated by Figure 5.805, all precedences between adjacent vertices of a same path hold: each item i ($1 \leq i \leq 7$) of the NODES collection is represented by a rectangle starting and ending at instants NODES$[i]$.start and NODES$[i]$.end; the number within each rectangle designates the index of the corresponding item within the NODES collection.



①	index − 1	succ − 2	start − 0	end − 1
②	index − 2	succ − 6	start − 3	end − 5
③	index − 3	succ − 4	start − 0	end − 3
④	index − 4	succ − 5	start − 4	end − 6
⑤	index − 5	succ − 7	start − 7	end − 8
⑥	index − 6	succ − 6	start − 7	end − 9
⑦	index − 7	succ − 7	start − 9	end − 10

NODES

Figure 5.805: The two paths of the **Example** slot represented as two sequences of tasks

Typical

NPATH $<$ |NODES|
|NODES| >1
NODES.start $<$ NODES.end

Symmetries

- Items of NODES are permutable.
- One and the same constant can be added to the start and end attributes of all items of NODES.

Arg. properties

Functional dependency: NPATH determined by NODES.

Remark

This constraint is related to the PATH constraint of **Ilog Solver**. It can also be directly expressed with the CYCLE [47] constraint of **CHIP** by using the *diff nodes* and the origin parameters. A generic model based on linear programming that handles paths, trees and cycles is presented in [255].

Reformulation

The TEMPORAL_PATH(NPATH, NODES) constraint can be expressed in term of a conjunction of one PATH constraint, |NODES| ELEMENT constraints, and |NODES| inequalities constraints:

- We pass to the PATH constraint the number of path variable NPATH as well as the items of the NODES collection form which we remove the start and end attributes.
- To the i-th ($1 \leq i \leq$ |NODES|) item of the NODES collection, we create a variable $Start_{succ_i}$ and an ELEMENT(NODES[i].succ, $\langle T_{i,1}, T_{i,2}, \ldots, T_{i,\text{NODES}}\rangle$, $Start_{succ_i}$) constraint, where $T_{i,j}$ = NODES[i].start if $i \neq j$ and $T_{i,i}$ = NODES[i].end otherwise.

- Finaly to the i-th $(1 \leq i \leq |\texttt{NODES}|)$ item of the NODES collection, we also create an inequality constraint $\texttt{NODES}[i].\texttt{end} \leq Start_{succ_i}$. Note that, since $T_{i,i}$ was initialised to $\texttt{NODES}[i].\texttt{end}$, the inequality $\texttt{NODES}[i].\texttt{end} \leq T_{i,j}$ holds when $i = j$.

With respect to the **Example** slot we get the following conjunction of constraints:

PATH$(2, \langle \texttt{index}-1\ \texttt{succ}-2, \texttt{index}-2\ \texttt{succ}-6, \texttt{index}-3\ \texttt{succ}-4,$
$\texttt{index}-4\ \texttt{succ}-5, \texttt{index}-5\ \texttt{succ}-7, \texttt{index}-6\ \texttt{succ}-6,$
$\texttt{index}-7\ \texttt{succ}-7\rangle),$
ELEMENT$(2, \langle 1,3,0,4,7,7,9\rangle, 3),$
ELEMENT$(6, \langle 1,5,0,4,7,7,9\rangle, 7),$
ELEMENT$(4, \langle 1,5,3,4,7,7,9\rangle, 4),$
ELEMENT$(5, \langle 1,5,3,6,7,7,9\rangle, 7),$
ELEMENT$(7, \langle 1,5,3,6,8,7,9\rangle, 9),$
ELEMENT$(6, \langle 1,5,3,6,8,9,9\rangle, 9),$
ELEMENT$(7, \langle 1,5,3,6,8,9,10\rangle, 10),$
$1 \leq 3, 5 \leq 7, 3 \leq 4, 6 \leq 7, 8 \leq 9, 9 \leq 9, 10 \leq 10.$

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	• nodes1.succ $=$ nodes2.index • nodes1.succ $=$ nodes1.index $\vee$ nodes1.end $\leq$ nodes2.start • nodes1.start $\leq$ nodes1.end • nodes2.start $\leq$ nodes2.end
Graph property(ies)	• **MAX_ID** ≤ 1 • **NCC** $=$ NPATH • **NVERTEX** $=$ |NODES|

Graph model The arc constraint is a conjunction of four conditions that respectively correspond to:

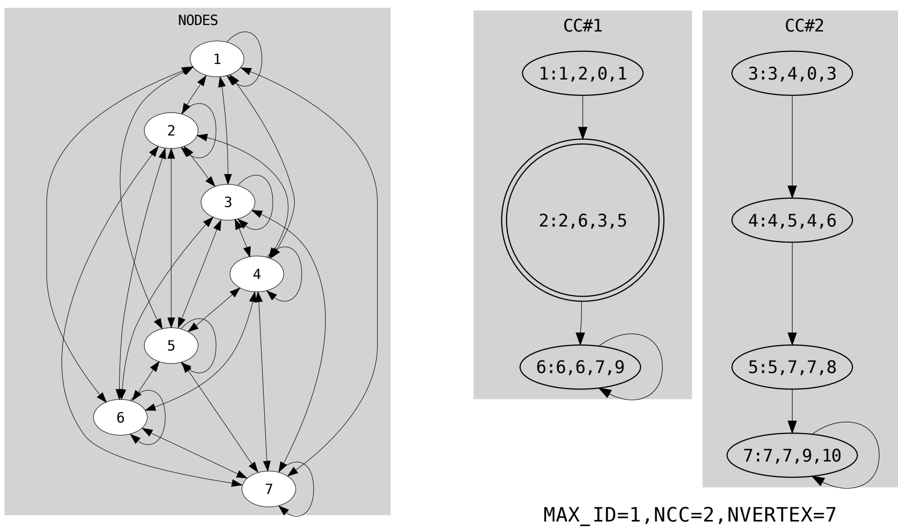
- A constraint that links the successor variable of a first vertex to the index attribute of a second vertex,
- A precedence constraint that applies on one vertex and its distinct successor,
- One precedence constraint between the start and the end of the vertex that corresponds to the departure of an arc,
- One precedence constraint between the start and the end of the vertex that corresponds to the arrival of an arc.

We use the following three graph properties in order to enforce the partitioning of the graph in distinct paths:

- The first property **MAX_ID** ≤ 1 enforces that each vertex has no more than one predecessor (**MAX_ID** does not consider loops),
- The second property **NCC** $=$ NPATH ensures that we have the required number of paths,
- The third property **NVERTEX** $=$ |NODES| enforces that, for each vertex, the start is not located after the end.

Parts (A) and (B) of Figure 5.806 respectively show the initial and final graph associated with the **Example** slot. Since we use the **MAX_ID**, the **NCC** and the **NVERTEX** graph properties we display the following information on the final graph:

- We show with a double circle a vertex that has the maximum number of predecessors.
- We show the two connected components corresponding to the two paths.
- We put in bold the vertices.



(A) **(B)**

Figure 5.806: Initial and final graph of the TEMPORAL_PATH constraint

5.409 TOUR

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin

[6]

Constraint

TOUR(NODES)

Synonyms

ATOUR, CYCLE.

Argument

NODES : collection(index−int, succ−svar)

Restrictions

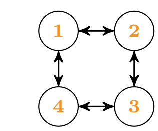
|NODES| ≥ 3
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES, index)

Purpose

Enforce to cover an undirected graph G described by the NODES collection with a Hamiltonian cycle.

Example

$$\left(\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-\{2,4\},\\ \texttt{index}-2 & \texttt{succ}-\{1,3\},\\ \texttt{index}-3 & \texttt{succ}-\{2,4\},\\ \texttt{index}-4 & \texttt{succ}-\{1,3\}\end{array}\right\rangle\right)$$



The TOUR constraint holds since its NODES argument depicts the following Hamiltonian cycle visiting successively the vertices 1, 2, 3 and 4.

Symmetry

Items of NODES are permutable.

Algorithm

When the number of vertices is odd (i.e., |NODES| is odd) a necessary condition is that the graph is not bipartite. Other necessary conditions for filtering the TOUR constraint are given in [140, 139].

See also

common keyword: CIRCUIT *(graph partitioning constraint,Hamiltonian)*, CYCLE *(graph constraint)*, LINK_SET_TO_BOOLEANS *(constraint involving set variables)*.

used in graph description: IN_SET.

Keywords

characteristic of a constraint: undirected graph.

combinatorial object: matching.

constraint arguments: constraint involving set variables.

problems: Hamiltonian.

Arc input(s)	NODES
Arc generator	$CLIQUE(\neq) \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	IN_SET(nodes2.index, nodes1.succ) $\Leftrightarrow$ IN_SET(nodes1.index, nodes2.succ)
Graph property(ies)	**NARC**$= \|$NODES$\| * \|$NODES$\| - \|$NODES$\|$

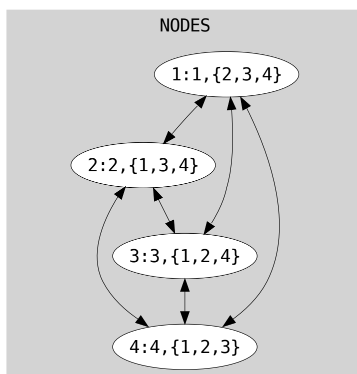
Arc input(s)	NODES
Arc generator	$CLIQUE(\neq) \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	IN_SET(nodes2.index, nodes1.succ)
Graph property(ies)	• **MIN_NSCC**$= \|$NODES$\|$ • **MIN_ID**$= 2$ • **MAX_ID**$= 2$ • **MIN_OD**$= 2$ • **MAX_OD**$= 2$

Graph model The first graph property enforces the subsequent condition: If we have an arc from the i^{th} vertex to the j^{th} vertex then we have also an arc from the j^{th} vertex to the i^{th} vertex. The second graph property enforces the following constraints:

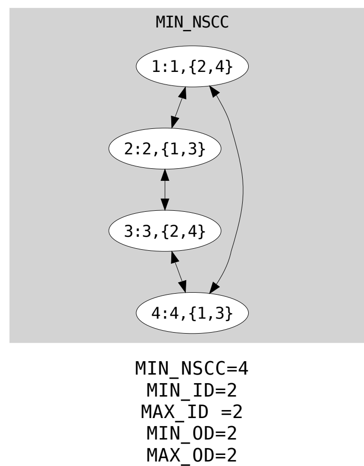
- We have one strongly connected component containing |NODES| vertices,
- Each vertex has exactly two predecessors and two successors.

Part (A) of Figure 5.807 shows the initial graph from which we start. It is derived from the set associated with each vertex. Each set describes the potential values of the succ attribute of a given vertex. Part (B) of Figure 5.807 gives the final graph associated with the **Example** slot. The TOUR constraint holds since the final graph corresponds to a Hamiltonian cycle.

Signature Since the maximum number of vertices of the final graph is equal to |NODES|, we can rewrite the graph property **MIN_NSCC** $=$ |NODES| to **MIN_NSCC** $\geq$ |NODES| and simplify $\underline{\textbf{MIN\_NSCC}}$ to $\overline{\textbf{MIN\_NSCC}}$.



(A)



(B)

Figure 5.807: Initial and final graph of the TOUR set constraint

5.410 TRACK

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin [285]

Constraint TRACK(NTRAIL, TASKS)

Arguments

NTRAIL : int
TASKS : collection(trail−int, origin−dvar, end−dvar)

Restrictions

$\mathtt{NTRAIL} > 0$
$\mathtt{NTRAIL} \leq |\mathtt{TASKS}|$
$|\mathtt{TASKS}| > 0$
required(TASKS, [trail, origin, end])
$\mathtt{TASKS.origin} \leq \mathtt{TASKS.end}$

Purpose

The TRACK constraint forces that, at each point in time overlapped by at least one task, the number of distinct values of the trail attribute of the set of tasks that overlap that point, is equal to NTRAIL.

Example

$$\left(2, \left\langle \begin{array}{lll} \mathtt{trail}-1 & \mathtt{origin}-1 & \mathtt{end}-2, \\ \mathtt{trail}-2 & \mathtt{origin}-1 & \mathtt{end}-2, \\ \mathtt{trail}-1 & \mathtt{origin}-2 & \mathtt{end}-4, \\ \mathtt{trail}-2 & \mathtt{origin}-2 & \mathtt{end}-3, \\ \mathtt{trail}-2 & \mathtt{origin}-3 & \mathtt{end}-4 \end{array} \right\rangle \right)$$

Figure 5.808 represents the tasks of the example: to the i^{th} task of the TASKS collection corresponds a rectangle labelled by i. The TRACK constraint holds since:

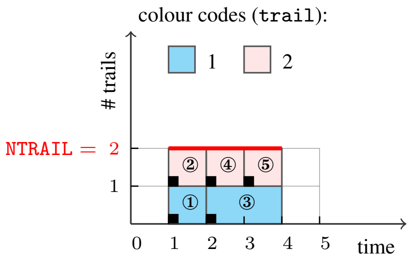
- The first and second tasks both overlap instant 1 and have a respective trail of 1 and 2. This makes two distinct values for the trail attribute at instant 1.
- The third and fourth tasks both overlap instant 2 and have a respective trail of 1 and 2. This makes two distinct values for the trail attribute at instant 2.
- The third and fifth tasks both overlap instant 3 and have a respective trail of 1 and 2. This makes two distinct values for the trail attribute at instant 3.

Typical

$\mathtt{NTRAIL} < |\mathtt{TASKS}|$
$|\mathtt{TASKS}| > 1$
$\mathrm{range}(\mathtt{TASKS.trail}) > 1$
$\mathtt{TASKS.origin} < \mathtt{TASKS.end}$

Symmetries

- Items of TASKS are permutable.
- All occurrences of two distinct values of TASKS.trail can be swapped; all occurrences of a value of TASKS.trail can be renamed to any unused value.
- One and the same constant can be added to the origin and end attributes of all items of TASKS.



TASKS

①	trail − 1	origin − 1	end − 2
②	trail − 2	origin − 1	end − 2
③	trail − 1	origin − 2	end − 4
④	trail − 2	origin − 2	end − 3
⑤	trail − 2	origin − 3	end − 4

Figure 5.808: The tasks associated with the example of the **Example** slot, at each instant we have two distinct values for the trail attribute (NTRAIL $= 2$)

Reformulation The TRACK constraint can be expressed in term of a set of reified constraints and of $2 \cdot |\texttt{TASKS}|$ NVALUE constraints:

1. For each pair of tasks $\texttt{TASKS}[i], \texttt{TASKS}[j]$ $(i, j \in [1, |\texttt{TASKS}|])$ of the TASKS collection we create a variable $T_{ij}^{\texttt{origin}}$ which is set to the trail attribute of task $\texttt{TASKS}[j]$ if task $\texttt{TASKS}[j]$ overlaps the origin attribute of task $\texttt{TASKS}[i]$, and to the trail attribute of task $\texttt{TASKS}[i]$ otherwise:
   - If $i = j$:
     - $T_{ij}^{\texttt{origin}} = \texttt{TASKS}[i].\texttt{trail}$.
   - If $i \neq j$:
     - $T_{ij}^{\texttt{origin}} = \texttt{TASKS}[i].\texttt{trail} \vee T_{ij}^{\texttt{origin}} = \texttt{TASKS}[j].\texttt{trail}$.
     - $((\texttt{TASKS}[j].\texttt{origin} \leq \texttt{TASKS}[i].\texttt{origin} \wedge$
       $\texttt{TASKS}[j].\texttt{end} > \texttt{TASKS}[i].\texttt{origin}) \wedge (T_{ij}^{\texttt{origin}} = \texttt{TASKS}[j].\texttt{trail})) \vee$
       $((\texttt{TASKS}[j].\texttt{origin} > \texttt{TASKS}[i].\texttt{origin} \vee$
       $\texttt{TASKS}[j].\texttt{end} \leq \texttt{TASKS}[i].\texttt{origin}) \wedge (T_{ij}^{\texttt{origin}} = \texttt{TASKS}[i].\texttt{trail}))$
2. For each task $\texttt{TASKS}[i]$ $(i \in [1, |\texttt{TASKS}|])$ we impose the number of distinct trails associated with the tasks that overlap the origin of task $\texttt{TASKS}[i]$ ($\texttt{TASKS}[i]$ overlaps its own origin) to be equal to NTRAIL:
   NVALUE$(\texttt{NTRAIL}, \langle T_{i1}^{\texttt{origin}}, T_{i2}^{\texttt{origin}}, \ldots, T_{i|\texttt{TASKS}|}^{\texttt{origin}} \rangle)$.
3. For each pair of tasks $\texttt{TASKS}[i], \texttt{TASKS}[j]$ $(i, j \in [1, |\texttt{TASKS}|])$ of the TASKS collection we create a variable $T_{ij}^{\texttt{end}}$ which is set to the trail attribute of task $\texttt{TASKS}[j]$ if task $\texttt{TASKS}[j]$ overlaps the end attribute of task $\texttt{TASKS}[i]$, and to the trail attribute of task $\texttt{TASKS}[i]$ otherwise:
   - If $i = j$:
     - $T_{ij}^{\texttt{end}} = \texttt{TASKS}[i].\texttt{trail}$.
   - If $i \neq j$:
     - $T_{ij}^{\texttt{end}} = \texttt{TASKS}[i].\texttt{trail} \vee T_{ij}^{\texttt{end}} = \texttt{TASKS}[j].\texttt{trail}$.
     - $((\texttt{TASKS}[j].\texttt{origin} \leq \texttt{TASKS}[i].\texttt{end} - 1 \wedge$
       $\texttt{TASKS}[j].\texttt{end} > \texttt{TASKS}[i].\texttt{end} - 1) \wedge (T_{ij}^{\texttt{end}} = \texttt{TASKS}[j].\texttt{trail})) \vee$
       $((\texttt{TASKS}[j].\texttt{origin} > \texttt{TASKS}[i].\texttt{end} - 1 \vee$
       $\texttt{TASKS}[j].\texttt{end} \leq \texttt{TASKS}[i].\texttt{end} - 1) \wedge (T_{ij}^{\texttt{end}} = \texttt{TASKS}[i].\texttt{trail}))$
4. For each task $\texttt{TASKS}[i]$ $(i \in [1, |\texttt{TASKS}|])$ we impose the number of distinct trails associated with the tasks that overlap the end of task $\texttt{TASKS}[i]$ ($\texttt{TASKS}[i]$ overlaps its

own end) to be equal to NTRAIL:
NVALUE(NTRAIL, $\langle T_{i1}^{\texttt{end}}, T_{i2}^{\texttt{end}}, \ldots, T_{i|\texttt{TASKS}|}^{\texttt{end}}\rangle$).

With respect to the **Example** slot we get the following conjunction of NVALUE constraints:

- The NVALUE$(2, \langle 1, 2, 1, 1, 1\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the origin of the first task (i.e., instant 1) that has a trail of 1.
- The NVALUE$(2, \langle 1, 2, 2, 2, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the origin of the second task (i.e., instant 1) that has a trail of 2.
- The NVALUE$(2, \langle 1, 1, 1, 2, 1\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the origin of the third task (i.e., instant 2) that has a trail of 1.
- The NVALUE$(2, \langle 2, 2, 1, 2, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the origin of the fourth task (i.e., instant 2) that has a trail of 2.
- The NVALUE$(2, \langle 2, 2, 1, 2, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the origin of the fifth task (i.e., instant 3) that has a trail of 2.
- The NVALUE$(2, \langle 1, 2, 1, 1, 1\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the last instant of the first task (i.e., instant 1) that has a trail of 1.
- The NVALUE$(2, \langle 1, 2, 2, 2, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the last instant of the second task (i.e., instant 1) that has a trail of 2.
- The NVALUE$(2, \langle 1, 1, 1, 1, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the last instant of the third task (i.e., instant 3) that has a trail of 1.
- The NVALUE$(2, \langle 2, 2, 1, 2, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the last instant of the fourth task (i.e., instant 2) that has a trail of 2.
- The NVALUE$(2, \langle 2, 2, 1, 2, 2\rangle)$ constraint corresponding to the `trail` attributes of the tasks that overlap the last instant of the fifth task (i.e., instant 3) that has a trail of 2.

Constraint(s) on sets NVALUE(NTRAIL, variables)

Graph model Parts (A) and (B) of Figure 5.809 respectively show the initial and final graph of the second graph constraint of the **Example** slot.

Signature Consider the first graph constraint. Since we use the $SELF$ arc generator on the TASKS collection, the maximum number of arcs of the final graph is equal to |TASKS|. Therefore we can rewrite **NARC** $=$ |TASKS| to **NARC** $\geq$ |TASKS| and simplify $\underline{\mathbf{NARC}}$ to $\overline{\mathbf{NARC}}$.

5.411 TREE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin N. Beldiceanu

Constraint TREE(NTREES, NODES)

Arguments

NTREES : dvar
NODES : collection(index−int, succ−dvar)

Restrictions

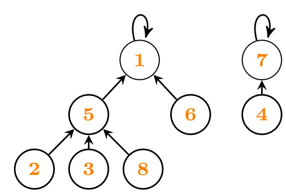
NTREES ≥ 1
NTREES $\leq$ |NODES|
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ $\leq$ |NODES|

Purpose

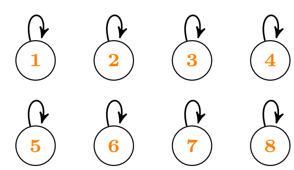
Given a digraph G described by the NODES collection, cover G by a set of NTREES trees in such a way that each vertex of G belongs to one distinct tree. The edges of the trees are directed from their leaves to their respective roots.

Example

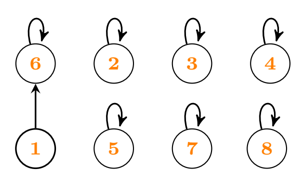
$$\left(2,\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-1,\\ \texttt{index}-2 & \texttt{succ}-5,\\ \texttt{index}-3 & \texttt{succ}-5,\\ \texttt{index}-4 & \texttt{succ}-7,\\ \texttt{index}-5 & \texttt{succ}-1,\\ \texttt{index}-6 & \texttt{succ}-1,\\ \texttt{index}-7 & \texttt{succ}-7,\\ \texttt{index}-8 & \texttt{succ}-5\end{array}\right\rangle\right)$$



$$\left(8,\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-1,\\ \texttt{index}-2 & \texttt{succ}-2,\\ \texttt{index}-3 & \texttt{succ}-3,\\ \texttt{index}-4 & \texttt{succ}-4,\\ \texttt{index}-5 & \texttt{succ}-5,\\ \texttt{index}-6 & \texttt{succ}-6,\\ \texttt{index}-7 & \texttt{succ}-7,\\ \texttt{index}-8 & \texttt{succ}-8\end{array}\right\rangle\right)$$



$$\left(7,\left\langle\begin{array}{ll}\texttt{index}-1 & \texttt{succ}-6,\\ \texttt{index}-2 & \texttt{succ}-2,\\ \texttt{index}-3 & \texttt{succ}-3,\\ \texttt{index}-4 & \texttt{succ}-4,\\ \texttt{index}-5 & \texttt{succ}-5,\\ \texttt{index}-6 & \texttt{succ}-6,\\ \texttt{index}-7 & \texttt{succ}-7,\\ \texttt{index}-8 & \texttt{succ}-8\end{array}\right\rangle\right)$$



The first TREE constraint holds since the graph associated with the items of the NODES collection corresponds to two trees (i.e., NTREES $= 2$): each tree respectively involves the vertices $\{1, 2, 3, 5, 6, 8\}$ and $\{4, 7\}$. They are depicted by Figure 5.810.

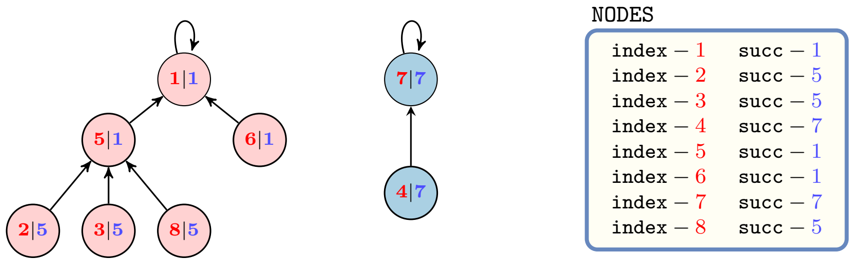


Figure 5.810: The two trees corresponding to the first example of the **Example** slot; each vertex contains the information index|succ where succ is the index of its father in the tree (by convention the father of the root is the root itself).

All solutions

Figure 5.811 gives all solutions to the following non ground instance of the TREE constraint: NTREES $\in [3, 4]$, $\mathtt{S}_1 \in [1, 2]$, $\mathtt{S}_2 \in [1, 3]$, $\mathtt{S}_3 \in [1, 4]$, $\mathtt{S}_4 \in [2, 4]$, TREE(NTREES, $\langle 1\ \mathtt{S}_1, 2\ \mathtt{S}_2, 3\ \mathtt{S}_3, 4\ \mathtt{S}_4\rangle$).

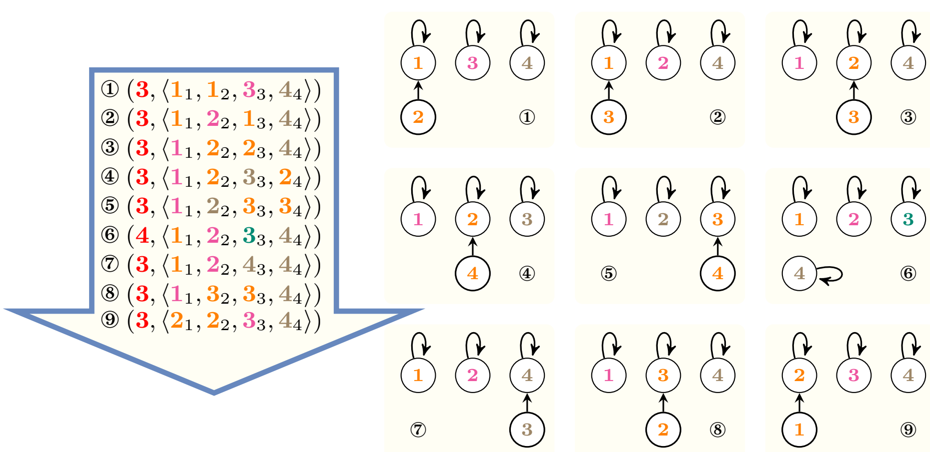

Figure 5.811: All solutions corresponding to the non ground example of the TREE constraint of the **All solutions** slot, where all vertices of a same tree are coloured by the same colour; in the left-hand side the index attributes are displayed as indices of the succ attribute, while in the right-hand side they are directly displayed within each node.

Typical

NTREES $<$ |NODES|
|NODES| > 2

Symmetry Items of NODES are permutable.

Arg. properties Functional dependency: NTREES determined by NODES.

Remark Given a complete digraph of n vertices as well as an unrestricted number of trees NTREES, the total number of solutions to the corresponding TREE constraint corresponds to the sequence A000272 of the On-Line Encyclopaedia of Integer Sequences [403].

In the context of an undirected weighted graph, extension of the TREE constraint to the *minimum spanning tree* constraint is described in [152, 360, 363].

Algorithm An arc-consistency filtering algorithm for the TREE constraint is described in [48]. This algorithm is based on a necessary and sufficient condition that we now depict.

To any TREE constraint we associate the digraph $G = (V, E)$, where:

- To each item NODES$[i]$ of the NODES collection corresponds a vertex v_i of G.
- For every pair of items (NODES$[i]$, NODES$[j]$) of the NODES collection, where i and j are not necessarily distinct, there is an arc from v_i to v_j in E if and only if j is a potential value of NODES$[i]$.succ.

A strongly connected component C of G is called a *sink component* if all the successors of all vertices of C belong to C. Let MINTREES and MAXTREES respectively denote the number of sink components of G and the number of vertices of G with a loop.

The TREE constraint has a solution if and only if:

- Each sink component of G contains at least one vertex with a loop,
- The domain of NTREES has at least one value within interval [MINTREES, MAXTREES].

Inspired by the idea of using dominators used in [234] for getting a linear time algorithm for computing strong articulation points of a digraph G, the worst case complexity of the algorithm proposed in [48] was also enhanced in a similar way by J.-G. Fages and X. Lorca [167].

Reformulation The TREE constraint can be expressed in term of (1) a set of $|\text{NODES}|^2$ reified constraints for avoiding circuit between more than one node and of (2) $|\text{NODES}|$ reified constraints and of one sum constraint for counting the trees:

1. For each vertex NODES$[i]$ ($i \in [1, |\text{NODES}|]$) of the NODES collection we create a variable r_i that takes its value within interval $[1, |\text{NODES}|]$. This variable represents the *rank* of vertex NODES$[i]$ within a solution. It is used to prevent the creation of circuit involving more than one vertex as explained now. For each pair of vertices NODES$[i]$, NODES$[j]$ ($i, j \in [1, |\text{NODES}|]$) of the NODES collection we create a reified constraint of the form NODES$[i]$.succ $=$ NODES$[j]$.index $\wedge\ i \neq j \Rightarrow r_i > r_j$. The purpose of this constraint is to express the fact that, if there is an arc from vertex NODES$[i]$ to another vertex NODES$[j]$, then r_i should be strictly greater than r_j.
2. For each vertex NODES$[i]$ ($i \in [1, |\text{NODES}|]$) of the NODES collection we create a 0-1 variable b_i and state the following reified constraint NODES$[i]$.succ $=$ NODES$[i]$.index $\Leftrightarrow b_i$ in order to force variable b_i to be set to value 1 if and only if there is a loop on vertex NODES$[i]$. Finally we create a constraint NTREES $= b_1 + b_2 + \cdots + b_{|\text{NODES}|}$ for stating the fact that the number of trees is equal to the number of loops of the graph.

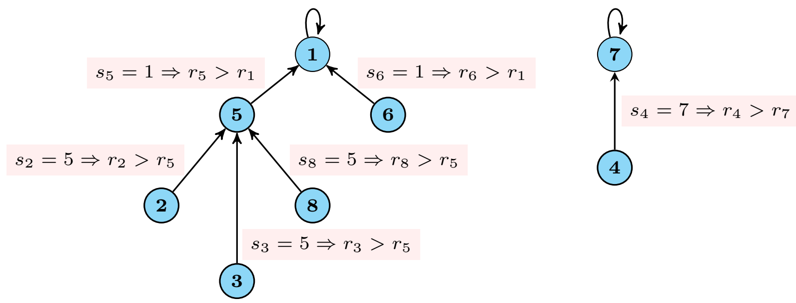

Figure 5.812: Illustrating the reformulation of the TREE constraint with rank variables for preventing the creation of circuits involving more than one vertex: the two trees corresponding to the first example of the **Example** slot with the link between the successor variables $s_1, s_2, \ldots, s_8$ and the rank variables $r_1, r_2, \ldots, r_8$

Figure 5.812 illustrates this reformulation on the first example of the **Example** slot.

Arc input(s)	NODES
Arc generator	$CLIQUE \mapsto$ collection(nodes1, nodes2)
Arc arity	2
Arc constraint(s)	nodes1.succ = nodes2.index
Graph property(ies)	• **MAX_NSCC** ≤ 1 • **NCC** = NTREES

Graph model We use the graph property **MAX_NSCC** ≤ 1 in order to specify the fact that the size of the largest strongly connected component should not exceed one. In fact each root of a tree is a strongly connected component with a single vertex. The second graph property **NCC** = NTREES enforces the number of trees to be equal to the number of connected components.

Parts (A) and (B) of Figure 5.813 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **NCC** graph property, we display the two connected components of the final graph. Each of them corresponds to a tree. The TREE constraint holds since all strongly connected components of the final graph have no more than one vertex and since NTREES = **NCC** = 2.

Figure 5.813: Initial and final graph of the TREE constraint

5.412 TREE_RANGE

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Derived from TREE.

Constraint TREE_RANGE(NTREES, R, NODES)

Arguments

NTREES	:	dvar
R	:	dvar
NODES	:	collection(index−int, succ−dvar)

Restrictions

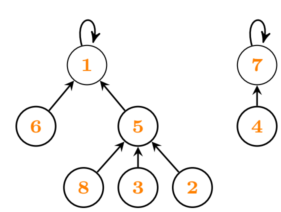
NTREES ≥ 0
R ≥ 0
R $<$ |NODES|
|NODES| > 0
required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index $\leq$ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ $\leq$ |NODES|

Purpose

Cover the digraph G described by the NODES collection with NTREES trees in such a way that each vertex of G belongs to one distinct tree. R is the difference between the longest and the shortest paths (from a leaf to a root) of the final graph.

Example

$$\left(2, 1, \left\langle \begin{array}{ll} \texttt{index}-1 & \texttt{succ}-1, \\ \texttt{index}-2 & \texttt{succ}-5, \\ \texttt{index}-3 & \texttt{succ}-5, \\ \texttt{index}-4 & \texttt{succ}-7, \\ \texttt{index}-5 & \texttt{succ}-1, \\ \texttt{index}-6 & \texttt{succ}-1, \\ \texttt{index}-7 & \texttt{succ}-7, \\ \texttt{index}-8 & \texttt{succ}-5 \end{array} \right\rangle \right)$$



The TREE_RANGE constraint holds since the graph associated with the items of the NODES collection corresponds to two trees (i.e., NTREES $= 2$): each tree respectively involves the vertices $\{1, 2, 3, 5, 6, 8\}$ and $\{4, 7\}$. Furthermore R $= 1$ is set to the difference between the longest path (for example, $2 \rightarrow 5 \rightarrow 1$) and the shortest path (for example, $4 \rightarrow 7$) from a leaf to a root. Figure 5.814 provides the two trees associated with the example.

All solutions

Figure 5.815 gives all solutions to the following non ground instance of the TREE_RANGE constraint: NTREES $\in [3, 4]$, R $= 2$, $\texttt{S}_1 \in [1, 2]$, $\texttt{S}_2 \in [1, 3]$, $\texttt{S}_3 \in [1, 4]$, $\texttt{S}_4 \in [2, 3]$, $\texttt{S}_5 \in [3, 4]$, $\texttt{S}_6 \in [4, 5]$, TREE_RANGE(NTREES, R, $\langle \texttt{S}_1, \texttt{S}_2, \texttt{S}_3, \texttt{S}_4, \texttt{S}_5, \texttt{S}_6 \rangle$).

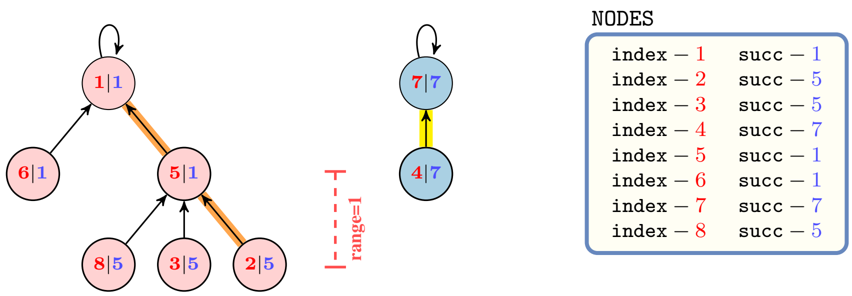


Figure 5.814: The two trees corresponding to the **Example** slot; each vertex contains the information index|succ where succ is the index of its father in the tree (by convention the father of the root is the root itself); the longest and shortest paths from a leaf to a root are respectively shown by thick orange and yellow line segments and have a length of 2 and 1; consequently the range is equal to 1.

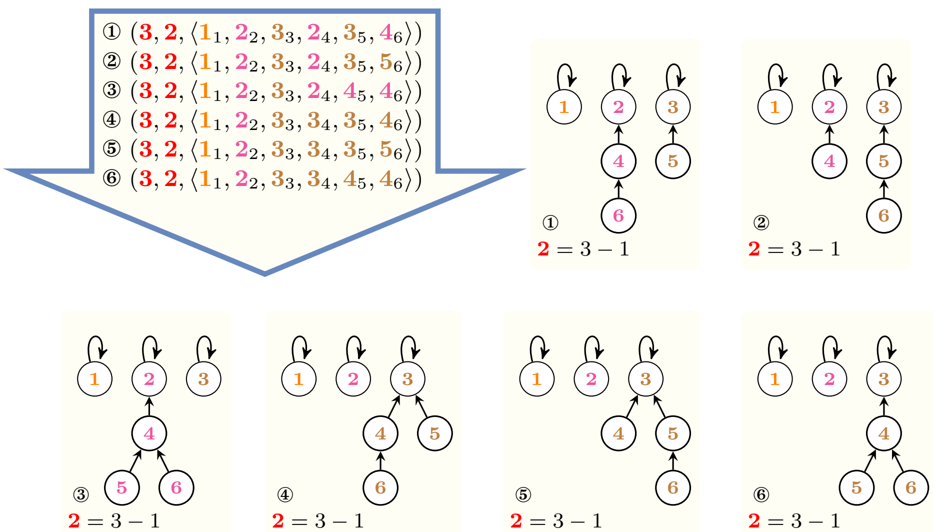

Figure 5.815: All solutions corresponding to the non ground example of the TREE_RANGE constraint of the **All solutions** slot, where all vertices of a same tree are coloured by the same colour; in the left-hand side the index attributes are displayed as indices of the succ attribute, while in the right-hand side they are directly displayed within each node; the bottom left part of each subfigure shows how the R argument (in red) is related to the longest and to the smallest paths from any leaf to the corresponding root.

Typical

NTREES $<$ |NODES|
|NODES| > 2

Symmetry Items of NODES are permutable.

Arg. properties

- Functional dependency: NTREES determined by NODES.
- Functional dependency: R determined by NODES.

Reformulation By introducing a *distance variable* D_i, an *occurrence variable* O_i and a *leave variable* L_i $(1 \leq i \leq |\texttt{NODES}|)$ for each item i of the NODES collection, where:

- D_i represents the number of vertices from i to the root of the corresponding tree,
- O_i gives the number of occurrences of value i within variables $\texttt{NODES}[1].\texttt{succ}, \texttt{NODES}[2].\texttt{succ}, \ldots, \texttt{NODES}[n].\texttt{succ}$,
- L_i is set to 1 if item i corresponds to a leave (i.e., $O_i > 0$) and 0 otherwise,

the TREE_RANGE(NTREES, R, NODES) constraint can be expressed in term of a conjunction of one TREE constraint, |NODES| ELEMENT constraints, |NODES| linear constraints, one GLOBAL_CARDINALITY constraint, |NODES| reified constraints, one OPEN_MINIMUM, one MAXIMUM and one linear constraint, where:

- The TREE constraint models the fact that we have a forest of NTREES trees.
- Each ELEMENT constraint provides the link between the attribute succ of the i-th item and the distance variable $D_{\texttt{NODES}[i].\texttt{succ}}$ associated with item $\texttt{NODES}[i].\texttt{succ}$.
- Each linear constraint associated with the i-th item states that the difference between the distance variable D_i and the distance variable $D_{\texttt{NODES}[i].\texttt{succ}}$ is equal to 1.
- The GLOBAL_CARDINALITY constraint provides the number of occurrences O_i of value i $(1 \leq i \leq |\texttt{NODES}|)$ within variables $\texttt{NODES}[1].\texttt{succ}, \texttt{NODES}[2].\texttt{succ}, \ldots, \texttt{NODES}[|\texttt{NODES}|].\texttt{succ}$. Note that, when O_i is equal to 0, the corresponding i-th item is a leave of one of the NTREES trees.
- Each reified constraint of the form $L_i \Leftrightarrow O_i > 0$ makes the link between the i-th occurrence variable O_i and the i-th leave variable L_i.
- The OPEN_MINIMUM constraint computes the minimum distance MIN from the leaves to the corresponding roots. The leave variable L_i is used in order to select only the distance variables corresponding to leaves.
- The MAXIMUM constraint computes the maximum distance MAX from the vertices to the roots. Since the maximum is achieved by a leave we do not need to focus just on the leaves as it was the case for the minimum distance MIN.
- The linear constraint $\texttt{MAX} - \texttt{MIN} = \texttt{R}$ links together argument R to the minimum and maximum distances.

With respect to the **Example** slot we get the following conjunction of constraints:

$$\begin{array}{l}
\text{TREE}(2, \langle \texttt{index}-1\ \texttt{succ}-1,\ \texttt{index}-2\ \texttt{succ}-5, \\
\quad \texttt{index}-3\ \texttt{succ}-5,\ \texttt{index}-4\ \texttt{succ}-7, \\
\quad \texttt{index}-5\ \texttt{succ}-1,\ \texttt{index}-6\ \texttt{succ}-1, \\
\quad \texttt{index}-7\ \texttt{succ}-7,\ \texttt{index}-8\ \texttt{succ}-5\rangle), \\
\text{DOMAIN}(\langle D_1, D_2, D_3, D_4, D_5, D_6, D_7, D_8\rangle, 0, 8), \\

(A) **(B)**

Figure 5.816: Initial and final graph of the TREE_RANGE constraint

5.413 TREE_RESOURCE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from TREE.

Constraint TREE_RESOURCE(RESOURCE, TASK)

Arguments

$$\begin{array}{lll} \text{RESOURCE} & : & \text{collection}(\text{id}-\text{int}, \text{nb\_task}-\text{dvar}) \\ \text{TASK} & : & \text{collection}(\text{id}-\text{int}, \text{father}-\text{dvar}, \text{resource}-\text{dvar}) \end{array}$$

Restrictions

$|\text{RESOURCE}| > 0$
$\text{required}(\text{RESOURCE}, [\text{id}, \text{nb\_task}])$
$\text{RESOURCE.id} \geq 1$
$\text{RESOURCE.id} \leq |\text{RESOURCE}|$
$\text{distinct}(\text{RESOURCE}, \text{id})$
$\text{RESOURCE.nb\_task} \geq 0$
$\text{RESOURCE.nb\_task} \leq |\text{TASK}|$
$\text{required}(\text{TASK}, [\text{id}, \text{father}, \text{resource}])$
$\text{TASK.id} > |\text{RESOURCE}|$
$\text{TASK.id} \leq |\text{RESOURCE}| + |\text{TASK}|$
$\text{distinct}(\text{TASK}, \text{id})$
$\text{TASK.father} \geq 1$
$\text{TASK.father} \leq |\text{RESOURCE}| + |\text{TASK}|$
$\text{TASK.resource} \geq 1$
$\text{TASK.resource} \leq |\text{RESOURCE}|$

Purpose

Cover a digraph G in such a way that each vertex belongs to one distinct tree. Each tree is made up from one *resource* vertex and several *task* vertices. The resource vertices correspond to the roots of the different trees. For each resource a domain variable nb_task indicates how many task-vertices belong to the corresponding tree. For each task a domain variable resource gives the identifier of the resource that can handle the task.

Example

$$\left(\begin{array}{l} \left\langle\begin{array}{ll} \text{id}-1 & \text{nb\_task}-4, \\ \text{id}-2 & \text{nb\_task}-0, \\ \text{id}-3 & \text{nb\_task}-1 \end{array}\right\rangle, \\ \left\langle\begin{array}{lll} \text{id}-4 & \text{father}-8 & \text{resource}-1, \\ \text{id}-5 & \text{father}-3 & \text{resource}-3, \\ \text{id}-6 & \text{father}-8 & \text{resource}-1, \\ \text{id}-7 & \text{father}-1 & \text{resource}-1, \\ \text{id}-8 & \text{father}-1 & \text{resource}-1 \end{array}\right\rangle \end{array}\right)$$

The TREE_RESOURCE constraint holds since the graph associated with the items of the RESOURCE and the TASK collections corresponds to 3 trees (i.e., $|\text{RESOURCE}| = 3$): each tree respectively involves the vertices $\{1, 4, 6, 7, 8\}$, $\{2\}$ and $\{3, 5\}$. They are depicted by Figure 5.817, where *resource* and *task* vertices are respectively coloured in blue and pink.

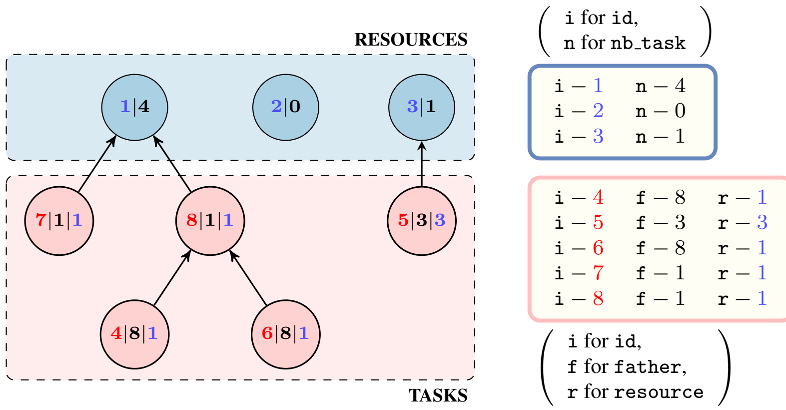

Figure 5.817: The three trees corresponding to the **Example** slot; each resource vertex (in blue) contains the information id|nb_task where nb_task is the number of tasks in the tree, while each task vertex (in pink) contains the information id|father|resource where father is the index of its father in the tree and resource is the index of the corresponding root task in the tree.

Typical

$|\mathtt{RESOURCE}| > 0$
$|\mathtt{TASK}| > |\mathtt{RESOURCE}|$

Symmetries

- Items of RESOURCE are permutable.
- Items of TASK are permutable.

Reformulation

The TREE_RESOURCE(RESOURCE, TASK) constraint can be expressed in term of a conjunction of one TREE constraint, |TASK| ELEMENT constraints and one GLOBAL_CARDINALITY constraint:

- The TREE constraint expresses the fact that we have a well formed tree.
- The ELEMENT constraint is used for expressing the link between the father attribute of an item of the TASK collection and its corresponding resource attribute.
- The GLOBAL_CARDINALITY constraint is used to link the resource attribute of the items of the TASK collection with the nb_task attribute of the items of the RESOURCE collection.

With respect to the **Example** slot we get the following conjunction of constraints:

TREE$(3, \langle$index $-\ 1$ succ $-\ 1,$
index $-\ 2$ succ $-\ 2,$
index $-\ 3$ succ $-\ 3,$
index $-\ 4$ succ $-\ 8,$
index $-\ 5$ succ $-\ 3,$
index $-\ 6$ succ $-\ 8,$
index $-\ 7$ succ $-\ 1,$
index $-\ 8$ succ $-\ 1\rangle),$
ELEMENT$(8, \langle 1, 2, 3, 1, 3, 1, 1, 1\rangle, 1),$

$\text{ELEMENT}(3, \langle 1, 2, 3, 1, 3, 1, 1, 1\rangle, 3)$,
$\text{ELEMENT}(8, \langle 1, 2, 3, 1, 3, 1, 1, 1\rangle, 1)$,
$\text{ELEMENT}(1, \langle 1, 2, 3, 1, 3, 1, 1, 1\rangle, 1)$,
$\text{ELEMENT}(1, \langle 1, 2, 3, 1, 3, 1, 1, 1\rangle, 1)$,
$\text{GLOBAL\_CARDINALITY}(\langle 1, 3, 1, 1, 1\rangle,$
$\langle \texttt{val} - 1\ \texttt{noccurrence} - 4,$
$\texttt{val} - 2\ \texttt{noccurrence} - 0,$
$\texttt{val} - 3\ \texttt{noccurrence} - 1\rangle)$.

See also **root concept:** TREE.

used in reformulation: ELEMENT, GLOBAL_CARDINALITY, TREE.

Keywords **characteristic of a constraint:** derived collection.

constraint type: graph constraint, resource constraint, graph partitioning constraint.

final graph structure: tree, connected component.

Derived Collection

$$\texttt{col}\left(\begin{array}{l}\texttt{RESOURCE\_TASK}-\texttt{collection}\left(\begin{array}{l}\texttt{index}-\texttt{int},\\ \texttt{succ}-\texttt{dvar},\\ \texttt{name}-\texttt{dvar}\end{array}\right),\\ \left[\begin{array}{l}\texttt{item}\left(\begin{array}{l}\texttt{index}-\texttt{RESOURCE.id},\\ \texttt{succ}-\texttt{RESOURCE.id},\\ \texttt{name}-\texttt{RESOURCE.id}\end{array}\right),\\ \texttt{item}\left(\begin{array}{l}\texttt{index}-\texttt{TASK.id},\\ \texttt{succ}-\texttt{TASK.father},\\ \texttt{name}-\texttt{TASK.resource}\end{array}\right)\end{array}\right]\end{array}\right)$$

Arc input(s) RESOURCE_TASK

Arc generator $CLIQUE \mapsto \texttt{collection}(\texttt{resource\_task1}, \texttt{resource\_task2})$

Arc arity 2

Arc constraint(s)
- $\texttt{resource\_task1.succ} = \texttt{resource\_task2.index}$
- $\texttt{resource\_task1.name} = \texttt{resource\_task2.name}$

Graph property(ies)
- $\mathbf{MAX\_NSCC} \leq 1$
- $\mathbf{NCC} = |\texttt{RESOURCE}|$
- $\mathbf{NVERTEX} = |\texttt{RESOURCE}| + |\texttt{TASK}|$

For all items of RESOURCE:

Arc input(s) RESOURCE_TASK

Arc generator $CLIQUE \mapsto \texttt{collection}(\texttt{resource\_task1}, \texttt{resource\_task2})$

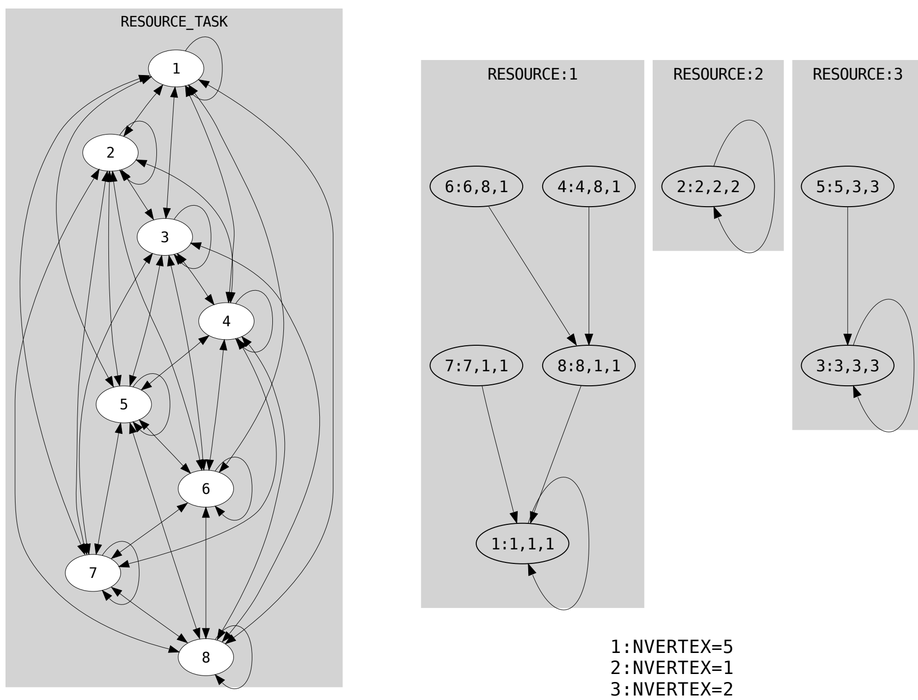
Arc arity 2

Arc constraint(s)
- $\texttt{resource\_task1.succ} = \texttt{resource\_task2.index}$
- $\texttt{resource\_task1.name} = \texttt{resource\_task2.name}$
- $\texttt{resource\_task1.name} = \texttt{RESOURCE.id}$

Graph property(ies) $\mathbf{NVERTEX} = \texttt{RESOURCE.nb\_task} + 1$

Graph model For the second graph constraint, part (A) of Figure 5.818 shows the initial graphs associated with resources 1, 2 and 3 of the **Example** slot. For the second graph constraint, part (B) of Figure 5.818 shows the corresponding final graphs associated with resources 1, 2 and 3. Since we use the **NVERTEX** graph property, the vertices of the final graphs are stressed in bold. To each resource corresponds a tree of respectively 4, 0 and 1 task-vertices.

Signature Since the initial graph of the first graph constraint contains $|\texttt{RESOURCE}| + |\texttt{TASK}|$ vertices, the corresponding final graph cannot have more than $|\texttt{RESOURCE}| + |\texttt{TASK}|$ vertices. Therefore we can rewrite the graph property $\mathbf{NVERTEX} = |\texttt{RESOURCE}| + |\texttt{TASK}|$ to $\mathbf{NVERTEX} \geq |\texttt{RESOURCE}| + |\texttt{TASK}|$ and simplify $\underline{\mathbf{NVERTEX}}$ to $\overline{\mathbf{NVERTEX}}$.



(A) **(B)**

Figure 5.818: Initial and final graph of the TREE_RESOURCE constraint

5.414 TWIN

▶ ▷ ◁ ◀ DESCRIPTION LINKS

Origin

Pairs of variables related by hiden ELEMENT constraints sharing the same table.

Constraint

TWIN(PAIRS)

Argument

PAIRS : collection(x−dvar, y−dvar)

Restrictions

required(PAIRS, x)
required(PAIRS, y)
$|\text{PAIRS}| > 0$

Purpose

Enforce the condition $\text{PAIRS}[i].\text{x} = u \wedge \text{PAIRS}[i].\text{y} = v \ (i \in [1, |\text{PAIRS}|]) \Rightarrow \forall j \in [1, |\text{PAIRS}|] : \text{PAIRS}[j].\text{x} = u \Leftrightarrow \text{PAIRS}[j].\text{y} = v$.

Example

$$\left(\left\langle\begin{array}{ll} \text{x}-1 & \text{y}-8, \\ \text{x}-9 & \text{y}-6, \\ \text{x}-1 & \text{y}-8, \\ \text{x}-5 & \text{y}-0, \\ \text{x}-6 & \text{y}-7, \\ \text{x}-9 & \text{y}-6 \end{array}\right\rangle\right)$$

The TWIN constraint holds since 1 is paired with 8, 9 is paired with 6, 5 is paired with 0, 6 is paired with 7.

Typical

$|\text{PAIRS}| > 1$
$|\text{PAIRS}| >$ nval(PAIRS.x)
$|\text{PAIRS}| >$ nval(PAIRS.y)
nval(PAIRS.x) > 1
nval(PAIRS.y) > 1
nval(PAIRS.x) = nval(PAIRS.y)
nval(PAIRS.x) $< |\text{PAIRS}|$
nval(PAIRS.y) $< |\text{PAIRS}|$

Arg. properties

Contractible wrt. PAIRS.

implied by: CIRCUIT, DERANGEMENT, PROPER_CIRCUIT, SYMMETRIC_ALLDIFFERENT_LOOP.

related: ELEMENT *(pairs linked by an element with the same table)*.

Keywords

characteristic of a constraint: pair.

constraint type: predefined constraint.

5.415 TWO_LAYER_EDGE_CROSSING

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Inspired by [212].

Constraint

$$\text{TWO\_LAYER\_EDGE\_CROSSING}\begin{pmatrix}\texttt{NCROSS},\\ \texttt{VERTICES\_LAYER1},\\ \texttt{VERTICES\_LAYER2},\\ \texttt{EDGES}\end{pmatrix}$$

Arguments

NCROSS	:	dvar
VERTICES_LAYER1	:	collection(id−int, pos−dvar)
VERTICES_LAYER2	:	collection(id−int, pos−dvar)
EDGES	:	collection(id−int, vertex1−int, vertex2−int)

Restrictions

NCROSS ≥ 0
required(VERTICES_LAYER1, [id, pos])
VERTICES_LAYER1.id ≥ 1
VERTICES_LAYER1.id $\leq$ |VERTICES_LAYER1|
distinct(VERTICES_LAYER1, id)
distinct(VERTICES_LAYER1, pos)
required(VERTICES_LAYER2, [id, pos])
VERTICES_LAYER2.id ≥ 1
VERTICES_LAYER2.id $\leq$ |VERTICES_LAYER2|
distinct(VERTICES_LAYER2, id)
distinct(VERTICES_LAYER2, pos)
required(EDGES, [id, vertex1, vertex2])
EDGES.id ≥ 1
EDGES.id $\leq$ |EDGES|
distinct(EDGES, id)
EDGES.vertex1 ≥ 1
EDGES.vertex1 $\leq$ |VERTICES_LAYER1|
EDGES.vertex2 ≥ 1
EDGES.vertex2 $\leq$ |VERTICES_LAYER2|

Purpose NCROSS is the number of line segments intersections.

Example

$$\left(\begin{array}{l} 2, \langle \texttt{id}-1\ \texttt{pos}-1, \texttt{id}-2\ \texttt{pos}-2\rangle, \\ \langle \texttt{id}-1\ \texttt{pos}-3, \texttt{id}-2\ \texttt{pos}-1, \texttt{id}-3\ \texttt{pos}-2\rangle, \\ \left\langle\begin{array}{lll} \texttt{id}-1 & \texttt{vertex1}-2 & \texttt{vertex2}-2, \\ \texttt{id}-2 & \texttt{vertex1}-2 & \texttt{vertex2}-3, \\ \texttt{id}-3 & \texttt{vertex1}-1 & \texttt{vertex2}-1 \end{array}\right\rangle \end{array}\right)$$

Figure 5.819 provides a picture of the example, where one can see the two line segments intersections. Each line segment of Figure 5.819 is labelled with its identifier and corresponds to an item of the EDGES collection. The two vertices on top of Figure 5.819 correspond to the items of the VERTICES_LAYER1 collection, while the three other vertices are associated with the items of VERTICES_LAYER2.

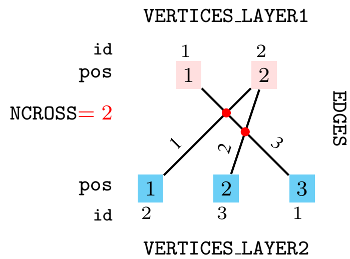

Figure 5.819: Intersection between line segments joining two layers of the **Example** slot for the constraint TWO_LAYER_EDGE_CROSSING(NCROSS, VERTICES_LAYER1, VERTICES_LAYER2, EDGES)

Typical

$|\mathtt{VERTICES\_LAYER1}| > 1$
$|\mathtt{VERTICES\_LAYER2}| > 1$
$|\mathtt{EDGES}| \geq |\mathtt{VERTICES\_LAYER1}|$
$|\mathtt{EDGES}| \geq |\mathtt{VERTICES\_LAYER2}|$

Symmetries

- Arguments are permutable w.r.t. permutation (NCROSS) (VERTICES_LAYER1, VERTICES_LAYER2) (EDGES).
- Items of VERTICES_LAYER1 are permutable.
- Items of VERTICES_LAYER2 are permutable.

Arg. properties

Functional dependency: NCROSS determined by VERTICES_LAYER1, VERTICES_LAYER2 and EDGES.

Remark

The two-layer edge crossing minimisation problem was proved to be NP-hard in [195].

See also

common keyword: CROSSING, GRAPH_CROSSING *(line segments intersection)*.

Keywords

characteristic of a constraint: derived collection.

constraint arguments: pure functional dependency.

geometry: geometrical constraint, line segments intersection.

miscellaneous: obscure.

modelling: functional dependency.

Derived Collection

$$\texttt{col}\left(\begin{array}{l}\texttt{EDGES\_EXTREMITIES}-\texttt{collection}(\texttt{layer1}-\texttt{dvar},\texttt{layer2}-\texttt{dvar}),\\ \left[\texttt{item}\left(\begin{array}{l}\texttt{layer1}-\texttt{EDGES.vertex1}(\texttt{VERTICES\_LAYER1},\texttt{pos},\texttt{id}),\\ \texttt{layer2}-\texttt{EDGES.vertex2}(\texttt{VERTICES\_LAYER2},\texttt{pos},\texttt{id})\end{array}\right)\right]\end{array}\right)$$

Arc input(s) EDGES_EXTREMITIES

Arc generator $CLIQUE(<)\mapsto\texttt{collection}(\texttt{edges\_extremities1},\texttt{edges\_extremities2})$

Arc arity 2

Arc constraint(s)

$$\bigvee\left(\begin{array}{l}\bigwedge\left(\begin{array}{l}\texttt{edges\_extremities1.layer1}<\texttt{edges\_extremities2.layer1},\\ \texttt{edges\_extremities1.layer2}>\texttt{edges\_extremities2.layer2}\end{array}\right),\\ \bigwedge\left(\begin{array}{l}\texttt{edges\_extremities1.layer1}>\texttt{edges\_extremities2.layer1},\\ \texttt{edges\_extremities1.layer2}<\texttt{edges\_extremities2.layer2}\end{array}\right)\end{array}\right)$$

Graph property(ies) $\mathbf{NARC}=\texttt{NCROSS}$

Graph model As usual for the two-layer edge crossing problem [212], [24], positions of the vertices on each layer are represented as a permutation of the vertices. We generate a derived collection that, for each edge, contains the position of its extremities on both layers. In the arc generator we use the restriction $<$ in order to generate a single arc for each pair of segments. This is required, since otherwise we would count more than once a line segments intersection.

Parts (A) and (B) of Figure 5.820 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

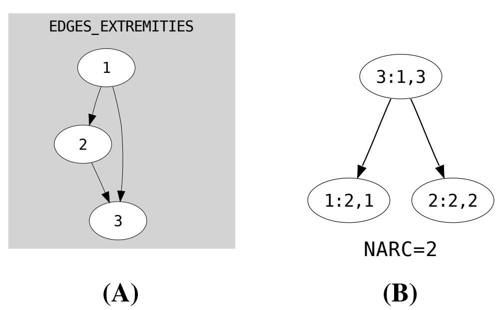

Figure 5.820: Initial and final graph of the TWO_LAYER_EDGE_CROSSING constraint

5.416 TWO_ORTH_ARE_IN_CONTACT

DESCRIPTION LINKS GRAPH AUTOMATON

Origin [369], used for defining ORTHS_ARE_CONNECTED.

Constraint TWO_ORTH_ARE_IN_CONTACT(ORTHOTOPE1, ORTHOTOPE2)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Arguments

ORTHOTOPE1 : ORTHOTOPE
ORTHOTOPE2 : ORTHOTOPE

Restrictions

|ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz > 0
ORTHOTOPE.ori ≤ ORTHOTOPE.end
|ORTHOTOPE1| = |ORTHOTOPE2|
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE1)
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE2)

Purpose

Enforce the following conditions on two orthotopes O_1 and O_2:

- For all dimensions i, except one dimension, the projections of O_1 and O_2 onto i have a non-empty intersection.
- For all dimensions i, the distance between the projections of O_1 and O_2 onto i is equal to 0.

Example

$$\left(\begin{array}{l}\langle \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4, \texttt{ori}-5\ \texttt{siz}-2\ \texttt{end}-7\rangle,\\ \langle \texttt{ori}-3\ \texttt{siz}-2\ \texttt{end}-5, \texttt{ori}-2\ \texttt{siz}-3\ \texttt{end}-5\rangle\end{array}\right)$$

Figure 5.821 shows the two rectangles of the example. The TWO_ORTH_ARE_IN_CONTACT constraint holds since the two rectangles are in contact: the contact is depicted by a pink line-segment.

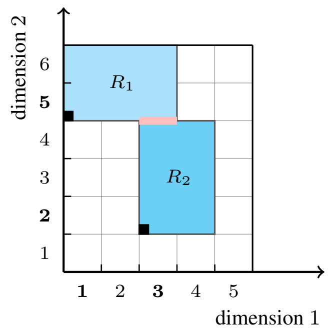
Typical |ORTHOTOPE| > 1

Symmetries

- Arguments are permutable w.r.t. permutation (ORTHOTOPE1, ORTHOTOPE2).
- Items of ORTHOTOPE1 and ORTHOTOPE2 are permutable (*same permutation used*).

Used in ORTHS_ARE_CONNECTED.

See also **implies:** TWO_ORTH_DO_NOT_OVERLAP.



R_1:	$\langle \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4, \texttt{ori}-5\ \texttt{siz}-2\ \texttt{end}-7\rangle$
R_2:	$\langle \texttt{ori}-3\ \texttt{siz}-2\ \texttt{end}-5, \texttt{ori}-2\ \texttt{siz}-3\ \texttt{end}-5\rangle$

`ORTHOTOPES` (rectangles)

Figure 5.821: The two rectangles that are in contact of the **Example** slot where the contact is shown in pink

Keywords

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: logic.

filtering: arc-consistency.

geometry: geometrical constraint, touch, contact, non-overlapping, orthotope.

Arc input(s) ORTHOTOPE1 ORTHOTOPE2

Arc generator $PRODUCT(=) \mapsto$ collection(orthotope1, orthotope2)

Arc arity 2

Arc constraint(s)
- orthotope1.end > orthotope2.ori
- orthotope2.end > orthotope1.ori

Graph property(ies) $\mathbf{NARC} = |\mathtt{ORTHOTOPE1}| - 1$

Arc input(s) ORTHOTOPE1 ORTHOTOPE2

Arc generator $PRODUCT(=) \mapsto$ collection(orthotope1, orthotope2)

Arc arity 2

Arc constraint(s) $\mathtt{max}\left(0, \begin{array}{l}\mathtt{max}(\mathtt{orthotope1.ori}, \mathtt{orthotope2.ori}) - \\ \mathtt{min}(\mathtt{orthotope1.end}, \mathtt{orthotope2.end})\end{array}\right) = 0$

Graph property(ies) $\mathbf{NARC} = |\mathtt{ORTHOTOPE1}|$

Graph model Parts (A) and (B) of Figure 5.822 respectively show the initial and final graph associated with the first graph constraint of the **Example** slot. Since we use the **NARC** graph property, the unique arc of the final graph is stressed in bold. It corresponds to the fact that the projection onto dimension 1 of the two rectangles of the example overlap.

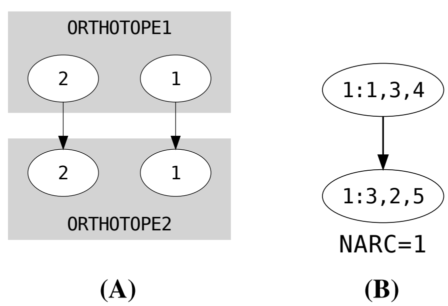


Figure 5.822: Initial and final graph of the TWO_ORTH_ARE_IN_CONTACT constraint

Signature Consider the second graph constraint. Since we use the arc generator $PRODUCT(=)$ on the collections ORTHOTOPE1 and ORTHOTOPE2, and because of the restriction $|\mathtt{ORTHOTOPE1}| = |\mathtt{ORTHOTOPE2}|$, the maximum number of arcs of the corresponding final graph is equal to $|\mathtt{ORTHOTOPE1}|$. Therefore we can rewrite the graph property $\mathbf{NARC} = |\mathtt{ORTHOTOPE1}|$ to $\mathbf{NARC} \geq |\mathtt{ORTHOTOPE1}|$ and simplify $\underline{\overline{\mathbf{NARC}}}$ to $\overline{\mathbf{NARC}}$.

Automaton Figure 5.823 depicts the automaton associated with the TWO_ORTH_ARE_IN_CONTACT constraint. Let $\mathtt{ORI1}_i$, $\mathtt{SIZ1}_i$ and $\mathtt{END1}_i$ respectively be the `ori`, the `siz` and the `end` attributes of the i^{th} item of the `ORTHOTOPE1` collection. Let $\mathtt{ORI2}_i$, $\mathtt{SIZ2}_i$ and $\mathtt{END2}_i$ respectively be the `ori`, the `siz` and the `end` attributes of the i^{th} item of the `ORTHOTOPE2` collection. To each sextuple $(\mathtt{ORI1}_i, \mathtt{SIZ1}_i, \mathtt{END1}_i, \mathtt{ORI2}_i, \mathtt{SIZ2}_i, \mathtt{END2}_i)$ corresponds a signature variable S_i, which takes its value in $\{0, 1, 2\}$, as well as the following signature constraint:

$$((\mathtt{SIZ1}_i > 0) \wedge (\mathtt{SIZ2}_i > 0) \wedge (\mathtt{END1}_i > \mathtt{ORI2}_i) \wedge (\mathtt{END2}_i > \mathtt{ORI1}_i)) \Leftrightarrow S_i = 0$$

$$((\mathtt{SIZ1}_i > 0) \wedge (\mathtt{SIZ2}_i > 0) \wedge (\mathtt{END1}_i = \mathtt{ORI2}_i \vee \mathtt{END2}_i = \mathtt{ORI1}_i)) \Leftrightarrow S_i = 1.$$

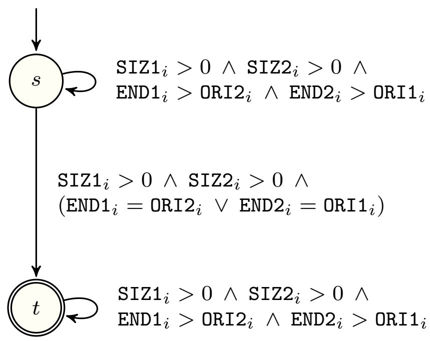

Figure 5.823: Automaton of the TWO_ORTH_ARE_IN_CONTACT constraint

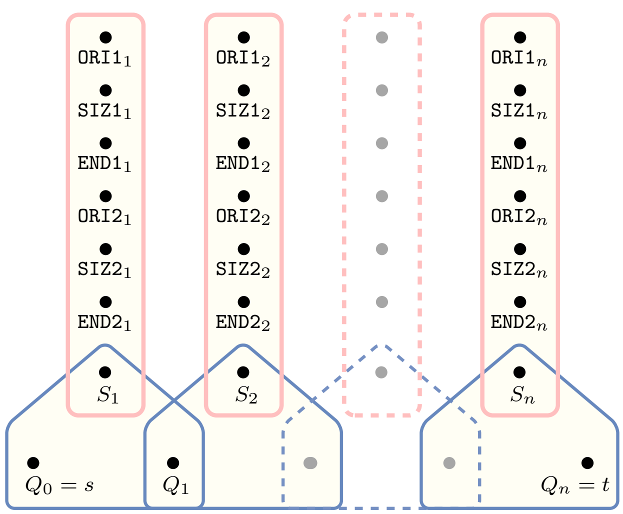

Figure 5.824: Hypergraph of the reformulation corresponding to the automaton of the TWO_ORTH_ARE_IN_CONTACT constraint

5.417 TWO_ORTH_COLUMN

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Used for defining DIFFN_COLUMN.

Constraint TWO_ORTH_COLUMN(ORTHOTOPE1, ORTHOTOPE2, DIM)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Arguments

ORTHOTOPE1	:	ORTHOTOPE
ORTHOTOPE2	:	ORTHOTOPE
DIM	:	int

Restrictions

|ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori ≤ ORTHOTOPE.end
|ORTHOTOPE1| = |ORTHOTOPE2|
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE1)
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE2)
DIM > 0
DIM ≤ |ORTHOTOPE1|

Purpose Let P_1 and P_2 respectively denote the projections of ORTHOTOPE1 and ORTHOTOPE2 onto dimension DIM. If P_1 and P_2 overlap then the size of their intersection is equal to the size of ORTHOTOPE1 in dimension DIM, as well as to the size of ORTHOTOPE2 in dimension DIM.

Example

$$\left(\begin{array}{l}\langle \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4, \texttt{ori}-1\ \texttt{siz}-1\ \texttt{end}-2\rangle,\\ \langle \texttt{ori}-4\ \texttt{siz}-2\ \texttt{end}-6, \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4\rangle, 1\end{array}\right)$$

Typical |ORTHOTOPE| > 1

Symmetry Arguments are permutable w.r.t. permutation (ORTHOTOPE1, ORTHOTOPE2) (DIM).

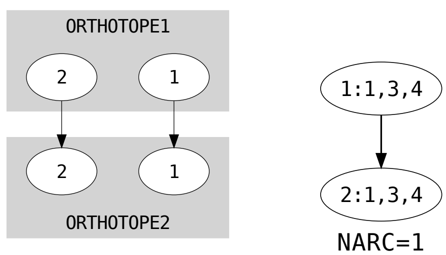
Used in DIFFN_COLUMN.

See also **implies:** TWO_ORTH_INCLUDE.

related: DIFFN *(an extension of the* DIFFN *constraint).*

Keywords **constraint type:** logic.

geometry: geometrical constraint, positioning constraint, orthotope, guillotine cut.



(A) **(B)**

Arc input(s) ORTHOTOPE1 ORTHOTOPE2

Arc generator $PRODUCT(=) \mapsto$ collection(orthotope1, orthotope2)

Arc arity 2

Arc constraint(s)

$$\bigwedge\left(\begin{array}{l}\texttt{orthotope1.key} = \texttt{DIM},\\ \texttt{orthotope1.ori} < \texttt{orthotope2.end},\\ \texttt{orthotope2.ori} < \texttt{orthotope1.end},\\ \texttt{orthotope1.siz} > 0,\\ \texttt{orthotope2.siz} > 0\end{array}\right) \Rightarrow \bigwedge\left(\begin{array}{l}\dfrac{\begin{array}{l}\texttt{min}(\texttt{orthotope1.end}, \texttt{orthotope2.end}) -\\ \texttt{max}(\texttt{orthotope1.ori}, \texttt{orthotope2.ori})\end{array}}{\texttt{orthotope1.siz}} = ,\\ \texttt{orthotope1.siz} = \texttt{orthotope2.siz}\end{array}\right)$$

Graph property(ies) **NARC** $= 1$

5.418 TWO_ORTH_DO_NOT_OVERLAP

DESCRIPTION LINKS GRAPH AUTOMATON

Origin Used for defining DIFFN.

Constraint TWO_ORTH_DO_NOT_OVERLAP(ORTHOTOPE1, ORTHOTOPE2)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Arguments

ORTHOTOPE1 : ORTHOTOPE
ORTHOTOPE2 : ORTHOTOPE

Restrictions

|ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori ≤ ORTHOTOPE.end
|ORTHOTOPE1| = |ORTHOTOPE2|
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE1)
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE2)

Purpose For two orthotopes O_1 and O_2 enforce that there exists at least one dimension i such that the projections on i of O_1 and O_2 do not overlap.

Example

$$\left(\begin{array}{l}\langle \texttt{ori}-2\ \texttt{siz}-2\ \texttt{end}-4, \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4\rangle, \\ \langle \texttt{ori}-4\ \texttt{siz}-4\ \texttt{end}-8, \texttt{ori}-3\ \texttt{siz}-3\ \texttt{end}-6\rangle\end{array}\right)$$

Figure 5.826 represents the respective position of the two rectangles of the example. The coordinates of the leftmost lowest corner of each rectangle are stressed in bold. The TWO_ORTH_DO_NOT_OVERLAP constraint holds since the two rectangles do not overlap.

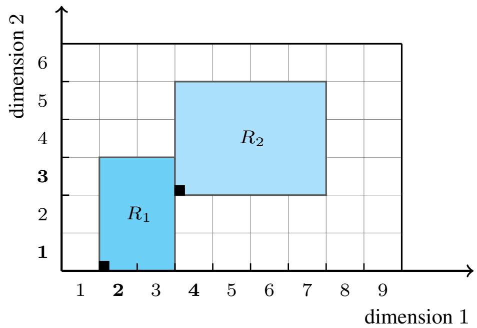
Typical |ORTHOTOPE| > 1

Symmetries

- Arguments are permutable w.r.t. permutation (ORTHOTOPE1, ORTHOTOPE2).
- Items of ORTHOTOPE1 and ORTHOTOPE2 are permutable (*same permutation used*).
- ORTHOTOPE1.siz can be decreased to any value ≥ 0.
- ORTHOTOPE2.siz can be decreased to any value ≥ 0.

Used in DIFFN.

See also **implied by:** TWO_ORTH_ARE_IN_CONTACT.



R_1: $\langle \texttt{ori}-2\ \texttt{siz}-2\ \texttt{end}-4, \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4\rangle$

`ORTHOTOPES` (rectangles)

Figure 5.826: The two non overlapping rectangles of the **Example** slot

Keywords

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: logic.

filtering: arc-consistency, constructive disjunction.

final graph structure: bipartite, no loop.

geometry: geometrical constraint, non-overlapping, orthotope.

Arc input(s)	ORTHOTOPE1 ORTHOTOPE2
Arc generator	$SYMMETRIC\_PRODUCT(=) \mapsto$ collection(orthotope1, orthotope2)
Arc arity	2
Arc constraint(s)	orthotope1.end $\leq$ orthotope2.ori $\vee$ orthotope1.siz $= 0$
Graph property(ies)	**NARC** ≥ 1
Graph class	• BIPARTITE • NO_LOOP

Graph model We build an initial graph where each arc corresponds to the fact that, either the projection of an orthotope on a given dimension is empty, either it is located before the projection in the same dimension of the other orthotope. Finally we ask that at least one arc constraint remains in the final graph.

Parts (A) and (B) of Figure 5.827 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the unique arc of the final graph is stressed in bold. It corresponds to the fact that the projection in dimension 1 of the first orthotope is located before the projection in dimension 1 of the second orthotope. Therefore the two orthotopes do not overlap.

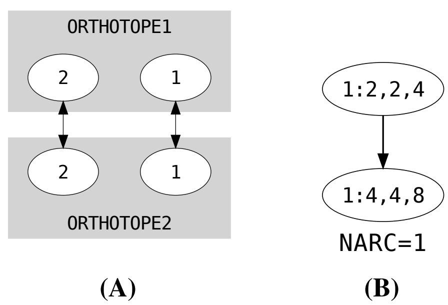

Figure 5.827: Initial and final graph of the TWO_ORTH_DO_NOT_OVERLAP constraint

Automaton Figure 5.828 depicts the automaton associated with the TWO_ORTH_DO_NOT_OVERLAP constraint. Let $\mathtt{ORI1}_i$, $\mathtt{SIZ1}_i$ and $\mathtt{END1}_i$ respectively be the ori, the siz and the end attributes of the i^{th} item of the ORTHOTOPE1 collection. Let $\mathtt{ORI2}_i$, $\mathtt{SIZ2}_i$ and $\mathtt{END2}_i$ respectively be the ori, the siz and the end attributes of the i^{th} item of the ORTHOTOPE2 collection. To each sextuple $(\mathtt{ORI1}_i, \mathtt{SIZ1}_i, \mathtt{END1}_i, \mathtt{ORI2}_i, \mathtt{SIZ2}_i, \mathtt{END2}_i)$ corresponds a 0-1 signature variable S_i as well as the following signature constraint: $((\mathtt{SIZ1}_i > 0) \wedge (\mathtt{SIZ2}_i > 0) \wedge (\mathtt{END1}_i > \mathtt{ORI2}_i) \wedge (\mathtt{END2}_i > \mathtt{ORI1}_i)) \Leftrightarrow S_i$.

5.419 TWO_ORTH_INCLUDE

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Used for defining DIFFN_INCLUDE.

Constraint TWO_ORTH_INCLUDE(ORTHOTOPE1, ORTHOTOPE2, DIM)

Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

Arguments

ORTHOTOPE1	:	ORTHOTOPE
ORTHOTOPE2	:	ORTHOTOPE
DIM	:	int

Restrictions

|ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori ≤ ORTHOTOPE.end
|ORTHOTOPE1| = |ORTHOTOPE2|
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE1)
ORTH_LINK_ORI_SIZ_END(ORTHOTOPE2)
DIM > 0
DIM ≤ |ORTHOTOPE1|

Purpose Let P_1 and P_2 respectively denote the projections of ORTHOTOPE1 and ORTHOTOPE2 onto dimension DIM. If P_1 and P_2 overlap then, either P_1 is included in P_2, either P_2 is included in P_1.

Example

$$\left(\begin{array}{l}\langle \texttt{ori}-1\ \texttt{siz}-3\ \texttt{end}-4, \texttt{ori}-1\ \texttt{siz}-1\ \texttt{end}-2\rangle, \\ \langle \texttt{ori}-1\ \texttt{siz}-2\ \texttt{end}-3, \texttt{ori}-2\ \texttt{siz}-3\ \texttt{end}-5\rangle, 1\end{array}\right)$$

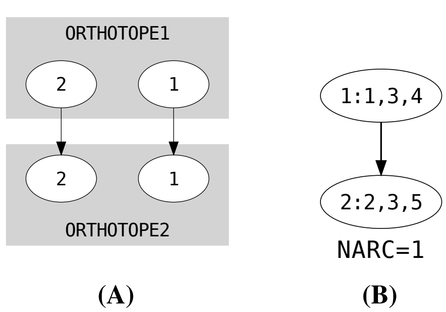

Figure 5.830: Initial and final graph of the TWO_ORTH_INCLUDE constraint

Typical $|\texttt{ORTHOTOPE}| > 1$

Symmetry Arguments are permutable w.r.t. permutation (ORTHOTOPE1, ORTHOTOPE2) (DIM).

Used in DIFFN_INCLUDE.

5.420 USED_BY

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH AUTOMATON

Origin N. Beldiceanu

Constraint USED_BY(VARIABLES1, VARIABLES2)

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)

Restrictions

$|\texttt{VARIABLES1}| \geq |\texttt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose All the values of the variables of collection VARIABLES2 are used by the variables of collection VARIABLES1.

Example $(\langle 1,9,1,5,2,1\rangle, \langle 1,1,2,5\rangle)$

The USED_BY constraint holds since, for each value occurring within the collection VARIABLES2 $= \langle 1,1,2,5\rangle$, its number of occurrences within VARIABLES1 $= \langle 1,9,1,5,2,1\rangle$ is greater than or equal to its number of occurrences within VARIABLES2:

- Value 1 occurs 3 times within $\langle 1,9,1,5,2,1\rangle$ and 2 times within $\langle 1,1,2,5\rangle$.
- Value 2 occurs 1 times within $\langle 1,9,1,5,2,1\rangle$ and 1 times within $\langle 1,1,2,5\rangle$.
- Value 5 occurs 1 times within $\langle 1,9,1,5,2,1\rangle$ and 1 times within $\langle 1,1,2,5\rangle$.

All solutions Figure 5.831 gives all solutions to the following non ground instance of the USED_BY constraint: $\texttt{U}_1 \in \{1,5\}$, $\texttt{U}_2 \in [1,2]$, $\texttt{U}_3 \in [1,2]$, $\texttt{V}_1 \in [0,2]$, $\texttt{V}_2 \in [2,4]$, USED_BY$(\langle \texttt{U}_1,\texttt{U}_2,\texttt{U}_3\rangle, \langle \texttt{V}_1,\texttt{V}_2\rangle)$.

Typical

$|\texttt{VARIABLES1}| > 1$
range(VARIABLES1.var) > 1
$|\texttt{VARIABLES2}| > 1$
range(VARIABLES2.var) > 1

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

① $(\langle 1, 1, 2\rangle, \langle 1, 2\rangle)$
② $(\langle 1, 2, 1\rangle, \langle 1, 2\rangle)$
③ $(\langle 1, 2, 2\rangle, \langle 1, 2\rangle)$
④ $(\langle 1, 2, 2\rangle, \langle 2, 2\rangle)$
⑤ $(\langle 5, 1, 2\rangle, \langle 1, 2\rangle)$
⑥ $(\langle 5, 2, 1\rangle, \langle 1, 2\rangle)$
⑦ $(\langle 5, 2, 2\rangle, \langle 2, 2\rangle)$

Figure 5.831: All solutions corresponding to the non ground example of the USED_BY constraint of the **All solutions** slot where identical values are coloured in the same way in both collections

Arg. properties

- Contractible wrt. VARIABLES2.
- Extensible wrt. VARIABLES1.
- Aggregate: VARIABLES1(union), VARIABLES2(union).

Algorithm

As described in [53] we can pad VARIABLES2 with dummy variables such that its cardinality will be equal to that cardinality of VARIABLES1. The domain of a dummy variable contains all of the values. Then, we have a SAME constraint between the two sets. Direct arc-consistency and bound-consistency algorithms based on a flow model are also proposed in [53, 55, 242]. The leftmost part of Figure 3.31 illustrates this flow model.

More recently [138, 139] presents a second filtering algorithm also achieving arc-consistency based on a mapping of the solutions to the USED_BY constraint to var-perfect matchings[17] in a bipartite intersection graph derived from the domain of the variables of the constraint in the following way. To each variable of the VARIABLES1 and VARIABLES2 collection corresponds a vertex of the intersection graph. There is an edge between a vertex associated with a variable of the VARIABLES1 collection and a vertex associated with a variable of the VARIABLES2 collection if and only if the corresponding variables have at least one value in common in their domains.

Reformulation

The USED_BY$(\langle \texttt{var}-U_1\ \texttt{var}-U_2, \ldots, \texttt{var}-U_{|\texttt{VARIABLES1}|}\rangle, \langle \texttt{var}-V_1\ \texttt{var}-V_2, \ldots, \texttt{var}-V_{|\texttt{VARIABLES2}|}\rangle)$ constraint can be expressed in term of a conjunction of $|\texttt{VARIABLES2}|$ reified constraints of the form:

$$\sum_{1\leq j\leq|\texttt{VARIABLES1}|}(V_i = U_j) \geq \sum_{1\leq j\leq|\texttt{VARIABLES2}|}(V_i = V_j)\ (i \in [1, |\texttt{VARIABLES2}|]).$$

Used in

INT_VALUE_PRECEDE_CHAIN, K_USED_BY.

See also

generalisation: USED_BY_INTERVAL *(*variable *replaced by* variable/constant*)*, USED_BY_MODULO *(*variable *replaced by* variable mod constant*)*, USED_BY_PARTITION *(*variable *replaced by* variable $\in$ partition*)*.

[17] A *var-perfect matching* is a maximum matching covering all vertices corresponding to the variables of VARIABLES2.

soft variant: SOFT_USED_BY_VAR *(variable-based violation measure)*.

system of constraints: K_USED_BY.

Keywords

characteristic of a constraint: sort based reformulation, automaton, automaton with array of counters.

combinatorial object: multiset.

constraint arguments: constraint between two collections of variables.

filtering: flow, bipartite matching, arc-consistency, bound-consistency, DFS-bottleneck.

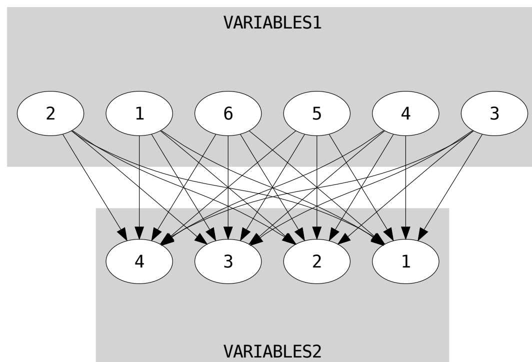
modelling: inclusion.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	*PRODUCT* $\mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	variables1.var = variables2.var
Graph property(ies)	• for all connected components: **NSOURCE** $\geq$ **NSINK** • **NSINK** $=$ |VARIABLES2|

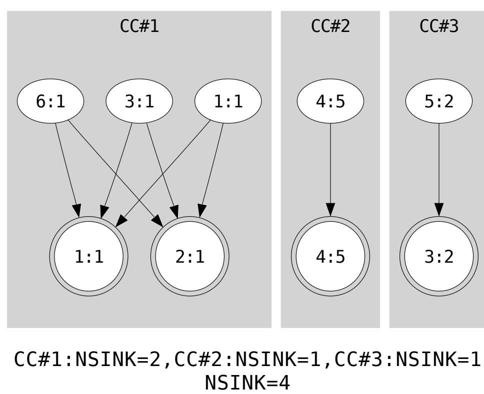
Graph model Parts (A) and (B) of Figure 5.832 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. Note that the vertex corresponding to the variable assigned to value 9 was removed from the final graph since there is no arc for which the associated equality constraint holds. The USED_BY constraint holds since:

- For each connected component of the final graph the number of sources is greater than or equal to the number of sinks.
- The number of sinks of the final graph is equal to |VARIABLES2|.

Signature Since the initial graph contains only sources and sinks, and since sources of the initial graph cannot become sinks of the final graph, we have that the maximum number of sinks of the final graph is equal to |VARIABLES2|. Therefore we can rewrite **NSINK** $=$ |VARIABLES2| to **NSINK** $\geq$ |VARIABLES2| and simplify $\underline{\overline{\mathbf{NSINK}}}$ to $\overline{\mathbf{NSINK}}$.



(A)



(B)

Figure 5.832: Initial and final graph of the USED_BY constraint

Automaton Figure 5.833 depicts the automaton associated with the USED_BY constraint. To each item of the collection VARIABLES1 corresponds a signature variable S_i that is equal to 0. To each item of the collection VARIABLES2 corresponds a signature variable $S_{i+|\texttt{VARIABLES1}|}$ that is equal to 1.

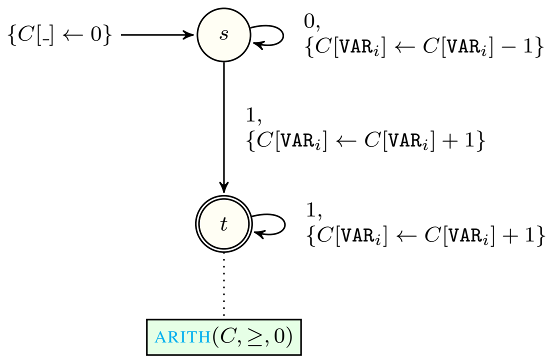


Figure 5.833: Automaton of the USED_BY constraint

5.421 USED_BY_INTERVAL

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin

Derived from USED_BY.

Constraint

USED_BY_INTERVAL(VARIABLES1, VARIABLES2, SIZE_INTERVAL)

Arguments

VARIABLES1	:	collection(var−dvar)
VARIABLES2	:	collection(var−dvar)
SIZE_INTERVAL	:	int

Restrictions

$|\mathtt{VARIABLES1}| \geq |\mathtt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
$\mathtt{SIZE\_INTERVAL} > 0$

Purpose

Let N_i (respectively M_i) denote the number of variables of the collection VARIABLES1 (respectively VARIABLES2) that take a value in the interval $[\mathtt{SIZE\_INTERVAL} \cdot i, \mathtt{SIZE\_INTERVAL} \cdot i + \mathtt{SIZE\_INTERVAL} - 1]$. For all integer i we have $M_i > 0 \Rightarrow N_i \geq M_i$.

Example

$(\langle 1, 9, 1, 8, 6, 2\rangle, \langle 1, 0, 7, 7\rangle, 3)$

In the example, the third argument $\mathtt{SIZE\_INTERVAL} = 3$ defines the following family of intervals $[3 \cdot k, 3 \cdot k + 2]$, where k is an integer. Consequently the values of the collection $\mathtt{VARIABLES2} = \langle 1, 0, 7, 7\rangle$ are respectively located within intervals $[0, 2]$, $[0, 2]$, $[6, 8]$, $[6, 8]$. Therefore intervals $[0, 2]$ and $[6, 8]$ are respectively used 2 and 2 times.

Similarly, the values of the collection $\mathtt{VARIABLES1} = \langle 1, 9, 1, 8, 6, 2\rangle$ are respectively located within intervals $[0, 2]$, $[9, 11]$, $[0, 2]$, $[6, 8]$, $[6, 8]$, $[0, 2]$. Therefore intervals $[0, 2]$, $[6, 8]$ and $[9, 11]$ are respectively used 3, 2 and 1 times.

Consequently, the USED_BY_INTERVAL constraint holds since, for each interval associated with the collection $\mathtt{VARIABLES2} = \langle 1, 0, 7, 7\rangle$, its number of occurrences within $\mathtt{VARIABLES1} = \langle 1, 9, 1, 8, 6, 2\rangle$ is greater than or equal to its number of occurrences within VARIABLES2:

- Interval $[0, 2]$ occurs 3 times within $\langle 1, 9, 1, 8, 6, 2\rangle$ and 2 times within $\langle 1, 0, 7, 7\rangle$.
- Interval $[6, 8]$ occurs 2 times within $\langle 1, 9, 1, 8, 6, 2\rangle$ and 2 times within $\langle 1, 0, 7, 7\rangle$.

Typical

$|\mathtt{VARIABLES1}| > 1$
range(VARIABLES1.var) > 1
$|\mathtt{VARIABLES2}| > 1$
range(VARIABLES2.var) > 1
$\mathtt{SIZE\_INTERVAL} > 1$
SIZE_INTERVAL < range(VARIABLES1.var)
SIZE_INTERVAL < range(VARIABLES2.var)

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value of VARIABLES1.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.
- An occurrence of a value of VARIABLES2.var that belongs to the k-th interval, of size SIZE_INTERVAL, can be replaced by any other value of the same interval.

Arg. properties

- Contractible wrt. VARIABLES2.
- Extensible wrt. VARIABLES1.
- Aggregate: VARIABLES1(union), VARIABLES2(union), SIZE_INTERVAL(id).

Reformulation

The USED_BY_INTERVAL($\langle \texttt{var}-U_1\ \texttt{var}-U_2, \dots, \texttt{var}-U_{|\texttt{VARIABLES1}|}\rangle$, $\langle \texttt{var}-V_1\ \texttt{var}-V_2, \dots, \texttt{var}-V_{|\texttt{VARIABLES2}|}\rangle$, SIZE_INTERVAL) constraint can be expressed by introducing $|\texttt{VARIABLES1}| + |\texttt{VARIABLES2}|$ *quotient* variables
$U_i = \texttt{SIZE\_INTERVAL} \cdot P_i + R_i$, $R_i \in [0, \texttt{SIZE\_INTERVAL}-1]$ $(i \in [1, |\texttt{VARIABLES1}|])$,
$V_i = \texttt{SIZE\_INTERVAL} \cdot Q_i + S_i$, $S_i \in [0, \texttt{SIZE\_INTERVAL}-1]$ $(i \in [1, |\texttt{VARIABLES2}|])$,
in term of a conjunction of $|\texttt{VARIABLES2}|$ reified constraints of the form:
$\sum_{1 \le j \le |\texttt{VARIABLES1}|} (Q_i = P_j) \ge \sum_{1 \le j \le |\texttt{VARIABLES2}|} (Q_i = Q_j)$ $(i \in [1, |\texttt{VARIABLES2}|])$.

Arc constraint(s)	`variables1.var`/`SIZE_INTERVAL` = `variables2.var`/`SIZE_INTERVAL`
Graph property(ies)	• for all connected components: **NSOURCE**≥**NSINK** • **NSINK**= |`VARIABLES2`|

Graph model Parts (A) and (B) of Figure 5.834 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. Note that the vertex corresponding to the variable that takes value 9 was removed from the final graph since there is no arc for which the associated equivalence constraint holds. The USED_BY_INTERVAL constraint holds since:

- For each connected component of the final graph the number of sources is greater than or equal to the number of sinks.
- The number of sinks of the final graph is equal to |`VARIABLES2`|.

Signature Since the initial graph contains only sources and sinks, and since sources of the initial graph cannot become sinks of the final graph, we have that the maximum number of sinks of the final graph is equal to |`VARIABLES2`|. Therefore we can rewrite **NSINK** = |`VARIABLES2`| to **NSINK** ≥ |`VARIABLES2`| and simplify $\underline{\mathbf{NSINK}}$ to $\overline{\mathbf{NSINK}}$.

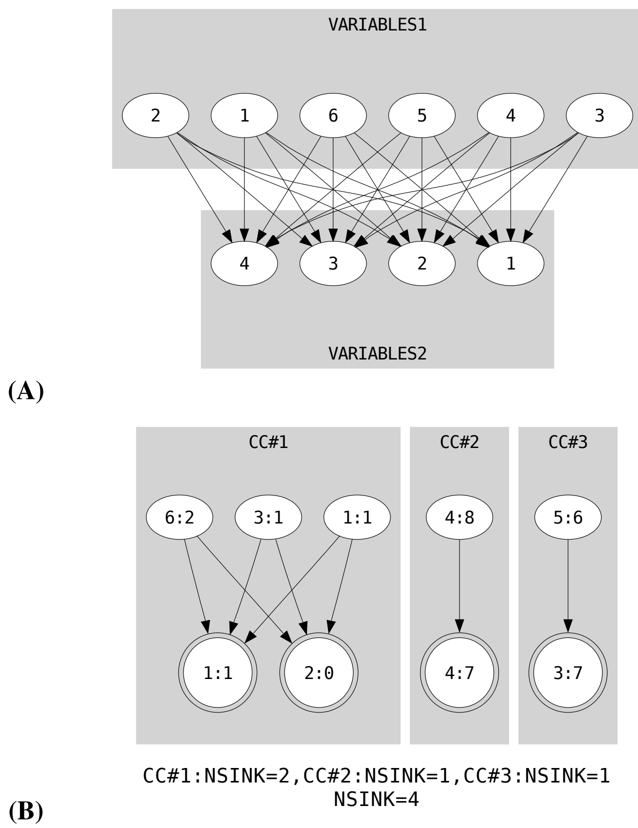

Figure 5.834: Initial and final graph of the USED_BY_INTERVAL constraint

5.422 USED_BY_MODULO

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY.

Constraint USED_BY_MODULO(VARIABLES1, VARIABLES2, M)

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)
M : int

Restrictions

$|\mathtt{VARIABLES1}| \geq |\mathtt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
$\mathtt{M} > 0$

Purpose

For each integer R in $[0, \mathtt{M}-1]$, let $N1_R$ (respectively $N2_R$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that have R as a rest when divided by M. For all R in $[0, \mathtt{M}-1]$ we have $N2_R > 0 \Rightarrow N1_R \geq N2_R$.

Example

$(\langle 1, 9, 4, 5, 2, 1\rangle, \langle 7, 1, 2, 5\rangle, 3)$

The values of the collection VARIABLES2 $= \langle 7, 1, 2, 5\rangle$ are respectively associated with the equivalence classes $7 \bmod 3 = 1$, $1 \bmod 3 = 1$, $2 \bmod 3 = 2$, $5 \bmod 3 = 2$. Therefore the equivalence classes 1 and 2 are respectively used 2 and 2 times.

Similarly, the values of the collection VARIABLES1 $= \langle 1, 9, 4, 5, 2, 1\rangle$ associated with the equivalence classes $1 \bmod 3 = 1$, $9 \bmod 3 = 0$, $4 \bmod 3 = 1$, $5 \bmod 3 = 2$, $2 \bmod 3 = 2$, $1 \bmod 3 = 1$. Therefore the equivalence classes 0, 1 and 2 are respectively used 1, 3 and 2 times.

Consequently, the USED_BY_MODULO constraint holds since, for each equivalence class associated with the collection VARIABLES2 $= \langle 7, 1, 2, 5\rangle$, its number of occurrences within VARIABLES1 $= \langle 1, 9, 4, 5, 2, 1\rangle$ is greater than or equal to its number of occurrences within VARIABLES2:

- The equivalence class 1 occurs 3 times within $\langle 1, 9, 4, 5, 2, 1\rangle$ and 2 times within $\langle 7, 1, 2, 5\rangle$.
- The equivalence class 2 occurs 2 times within $\langle 1, 9, 4, 5, 2, 1\rangle$ and 2 times within $\langle 7, 1, 2, 5\rangle$.

Typical

$|\mathtt{VARIABLES1}| > 1$
range(VARIABLES1.var) > 1
$|\mathtt{VARIABLES2}| > 1$
range(VARIABLES2.var) > 1
$\mathtt{M} > 1$
M $<$ maxval(VARIABLES1.var)
M $<$ maxval(VARIABLES2.var)

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value u of VARIABLES1.var can be replaced by any other value v such that v is congruent to u modulo M.
- An occurrence of a value u of VARIABLES2.var can be replaced by any other value v such that v is congruent to u modulo M.

Arg. properties

- Contractible wrt. VARIABLES2.
- Extensible wrt. VARIABLES1.
- Aggregate: VARIABLES1(union), VARIABLES2(union), M(id).

Used in K_USED_BY_MODULO.

See also

implied by: SAME_MODULO.

(B)

Figure 5.835: Initial and final graph of the USED_BY_MODULO constraint

5.423 USED_BY_PARTITION

▶ ▷ ◁ ◀ DESCRIPTION LINKS GRAPH

Origin Derived from USED_BY.

Constraint USED_BY_PARTITION(VARIABLES1, VARIABLES2, PARTITIONS)

Type

VALUES : collection(val−int)

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)
PARTITIONS : collection(p − VALUES)

Restrictions

$|\texttt{VALUES}| \geq 1$
required(VALUES, val)
distinct(VALUES, val)
$|\texttt{VARIABLES1}| \geq |\texttt{VARIABLES2}|$
required(VARIABLES1, var)
required(VARIABLES2, var)
required(PARTITIONS, p)
$|\texttt{PARTITIONS}| \geq 2$

Purpose

For each integer i in $[1, |\texttt{PARTITIONS}|]$, let $N1_i$ (respectively $N2_i$) denote the number of variables of VARIABLES1 (respectively VARIABLES2) that take their values in the i^{th} partition of the collection PARTITIONS. For all i in $[1, |\texttt{PARTITIONS}|]$ we have $N2_i > 0 \Rightarrow N1_i \geq N2_i$.

Example

$$\left(\begin{array}{l} \langle 1,9,1,6,2,3\rangle, \\ \langle 1,3,6,6\rangle, \\ \langle \texttt{p}-\langle 1,3\rangle, \texttt{p}-\langle 4\rangle, \texttt{p}-\langle 2,6\rangle\rangle \end{array}\right)$$

The different values of the collection VARIABLES2 $= \langle 1,3,6,6\rangle$ are respectively associated with the partitions $\texttt{p}-\langle 1,3\rangle$, $\texttt{p}-\langle 1,3\rangle$, $\texttt{p}-\langle 2,6\rangle$, and $\texttt{p}-\langle 2,6\rangle$. Therefore partitions $\texttt{p}-\langle 1,3\rangle$ and $\texttt{p}-\langle 2,6\rangle$ are respectively used 2 and 2 times.

Similarly, the different values of the collection VARIABLES1 $= \langle 1,9,1,6,2,3\rangle$ (except value 9, which does not occur in any partition) are respectively associated with the partitions $\texttt{p}-\langle 1,3\rangle$, $\texttt{p}-\langle 1,3\rangle$, $\texttt{p}-\langle 2,6\rangle$, $\texttt{p}-\langle 2,6\rangle$, and $\texttt{p}-\langle 1,3\rangle$. Therefore partitions $\texttt{p}-\langle 1,3\rangle$ and $\texttt{p}-\langle 2,6\rangle$ are respectively used 3 and 2 times.

Consequently, the USED_BY_PARTITION constraint holds since, for each partition associated with the collection VARIABLES2 $= \langle 1,3,6,6\rangle$, its number of occurrences within VARIABLES1 $= \langle 1,9,1,6,2,3\rangle$ is greater than or equal to its number of occurrences within VARIABLES2:

- Partition $\texttt{p}-\langle 1,3\rangle$ occurs 3 times within $\langle 1,9,1,6,2,3\rangle$ and 2 times within $\langle 1,3,6,6\rangle$.

- Partition p $-$ $\langle 2, 6\rangle$ occurs 2 times within $\langle 1, 9, 1, 6, 2, 3\rangle$ and 2 times within $\langle 1, 3, 6, 6\rangle$.

Typical

$|$VARIABLES1$| > 1$
range(VARIABLES1.var) > 1
$|$VARIABLES2$| > 1$
range(VARIABLES2.var) > 1
$|$VARIABLES1$| > |$PARTITIONS$|$
$|$VARIABLES2$| > |$PARTITIONS$|$

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of VARIABLES1.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.
- An occurrence of a value of VARIABLES2.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Arg. properties

- Contractible wrt. VARIABLES2.
- Extensible wrt. VARIABLES1.
- Aggregate: VARIABLES1(union), VARIABLES2(union), PARTITIONS(id).

Used in K_USED_BY_PARTITION.

See also

implied by: SAME_PARTITION.

soft variant: SOFT_USED_BY_PARTITION_VAR *(variable-based violation measure)*.

specialisation: USED_BY *(*variable $\in$ partition *replaced by* variable*)*.

system of constraints: K_USED_BY_PARTITION.

used in graph description: IN_SAME_PARTITION.

Keywords

characteristic of a constraint: partition, sort based reformulation.

constraint arguments: constraint between two collections of variables.

modelling: inclusion.

Arc input(s)	VARIABLES1 VARIABLES2
Arc generator	$PRODUCT \mapsto$ collection(variables1, variables2)
Arc arity	2
Arc constraint(s)	IN_SAME_PARTITION(variables1.var, variables2.var, PARTITIONS)
Graph property(ies)	• for all connected components: **NSOURCE**$\geq$**NSINK** • **NSINK**$=$ |VARIABLES2|

Graph model

Parts (A) and (B) of Figure 5.836 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NSOURCE** and **NSINK** graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since there is a constraint on each connected component of the final graph we also show the different connected components. Each of them corresponds to an equivalence class according to the arc constraint. Note that the vertex corresponding to the variable that takes value 9 was removed from the final graph since there is no arc for which the associated equivalence constraint holds. The USED_BY_PARTITION constraint holds since:

- For each connected component of the final graph the number of sources is greater than or equal to the number of sinks.
- The number of sinks of the final graph is equal to |VARIABLES2|.

Signature

Since the initial graph contains only sources and sinks, and since sources of the initial graph cannot become sinks of the final graph, we have that the maximum number of sinks of the final graph is equal to |VARIABLES2|. Therefore we can rewrite **NSINK** $=$ |VARIABLES2| to **NSINK** $\geq$ |VARIABLES2| and simplify $\underline{\textbf{NSINK}}$ to $\overline{\textbf{NSINK}}$.

5.424 USES

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin [69]

Constraint USES(VARIABLES1, VARIABLES2)

Arguments

VARIABLES1 : collection(var−dvar)
VARIABLES2 : collection(var−dvar)

Restrictions

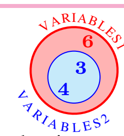
$\texttt{min}(1, |\texttt{VARIABLES1}|) \geq \texttt{min}(1, |\texttt{VARIABLES2}|)$
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose

The set of values assigned to the variables of the collection of variables VARIABLES2 is included within the set of values assigned to the variables of the collection of variables VARIABLES1.

Example

$(\langle 3, 3, 4, 6\rangle, \langle 3, 4, 4, 4, 4\rangle)$



The USES constraint holds since the set of values $\{3, 4\}$ assigned to the items of collection $\langle 3, 4, 4, 4, 4\rangle$ is included within the set of values $\{3, 4, 6\}$ occurring within $\langle 3, 3, 4, 6\rangle$.

All solutions

Figure 5.837 gives all solutions to the following non ground instance of the USES constraint: $\texttt{U}_1 \in [0, 1]$, $\texttt{U}_2 \in [1, 2]$, $\texttt{V}_1 \in [0, 2]$, $\texttt{V}_2 \in [2, 4]$, $\texttt{V}_3 \in [2, 4]$, $\text{USES}(\langle \texttt{U}_1, \texttt{U}_2\rangle, \langle \texttt{V}_1, \texttt{V}_2, \texttt{V}_3\rangle)$.

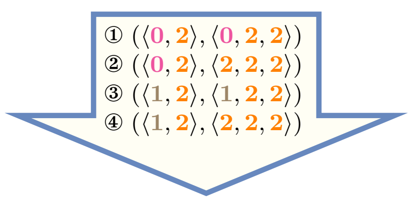


Figure 5.837: All solutions corresponding to the non ground example of the USES constraint of the **All solutions** slot where identical values are coloured in the same way in both collections

Typical

$|\texttt{VARIABLES1}| > 1$
$\texttt{range}(\texttt{VARIABLES1.var}) > 1$
$|\texttt{VARIABLES2}| > 1$
$\texttt{range}(\texttt{VARIABLES2.var}) > 1$
$|\texttt{VARIABLES1}| \leq |\texttt{VARIABLES2}|$

Symmetries

- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Arg. properties

- Contractible wrt. VARIABLES2.
- Extensible wrt. VARIABLES1.
- Aggregate: VARIABLES1(union), VARIABLES2(union).

Remark

It was shown in [69] that, finding out whether a USES constraint has a solution or not is NP-hard. This was achieved by reduction from 3-SAT.

5.425 VALLEY

► ▷ ◁ ◄ DESCRIPTION LINKS AUTOMATON

Origin

Derived from INFLEXION.

Constraint

VALLEY(N, VARIABLES)

Arguments

N : dvar
VARIABLES : collection(var−dvar)

Restrictions

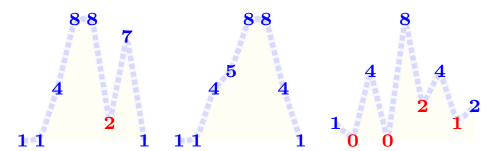
$\mathtt{N} \geq 0$
$2 * \mathtt{N} \leq \mathtt{max}(|\mathtt{VARIABLES}| - 1, 0)$
required(VARIABLES, var)

Purpose

A variable V_v $(1 < v < m)$ of the sequence of variables $\mathtt{VARIABLES} = V_1, \ldots, V_m$ is a *valley* if and only if there exists an i (with $1 < i \leq v$) such that $V_{i-1} > V_i$ and $V_i = V_{i+1} = \cdots = V_v$ and $V_v < V_{v+1}$. N is the total number of valleys of the sequence of variables VARIABLES.

Example

$(1, \langle 1, 1, 4, 8, 8, 2, 7, 1\rangle)$
$(0, \langle 1, 1, 4, 5, 8, 8, 4, 1\rangle)$
$(4, \langle 1, 0, 4, 0, 8, 2, 4, 1, 2\rangle)$



The first VALLEY constraint holds since the sequence 1 1 4 8 8 2 7 1 contains one valley that corresponds to the variable that is assigned to value 2.

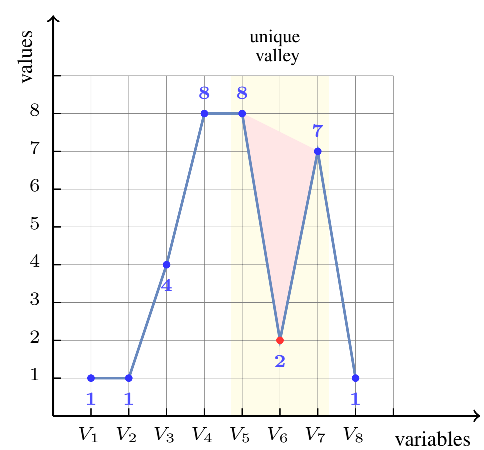


Figure 5.839: Illustration of the first example of the **Example** slot: a sequence of eight variables V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8 respectively fixed to values 1, 1, 4, 8, 8, 2, 7, 1 and its corresponding unique valley ($\mathtt{N} = 1$)

All solutions

Figure 5.840 gives all solutions to the following non ground instance of the VALLEY constraint: $\mathtt{N} \in [1,2]$, $\mathtt{V}_1 \in [0,1]$, $\mathtt{V}_2 \in [0,2]$, $\mathtt{V}_3 \in [0,2]$, $\mathtt{V}_4 \in [0,1]$, VALLEY$(\mathtt{N}, \langle \mathtt{V}_1, \mathtt{V}_2, \mathtt{V}_3, \mathtt{V}_4 \rangle)$.

① $(\mathbf{1}, \langle 0, 1, 0, 1 \rangle)$
② $(\mathbf{1}, \langle 0, 2, 0, 1 \rangle)$
③ $(\mathbf{1}, \langle 1, 0, 0, 1 \rangle)$
④ $(\mathbf{1}, \langle 1, 0, 1, 0 \rangle)$
⑤ $(\mathbf{1}, \langle 1, 0, 1, 1 \rangle)$
⑥ $(\mathbf{1}, \langle 1, 0, 2, 0 \rangle)$
⑦ $(\mathbf{1}, \langle 1, 0, 2, 1 \rangle)$
⑧ $(\mathbf{1}, \langle 1, 1, 0, 1 \rangle)$
⑨ $(\mathbf{1}, \langle 1, 2, 0, 1 \rangle)$

Figure 5.840: All solutions corresponding to the non ground example of the VALLEY constraint of the **All solutions** slot where each valley is coloured in orange

Typical

$|\mathtt{VARIABLES}| > 2$
$\mathtt{range}(\mathtt{VARIABLES.var}) > 1$

Typical model

$\mathtt{nval}(\mathtt{VARIABLES.var}) > 2$

Symmetries

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

- Functional dependency: N determined by VARIABLES.
- Contractible wrt. VARIABLES when $\mathtt{N} = 0$.

Usage

Useful for constraining the number of *valleys* of a sequence of domain variables.

Remark

Since the arity of the arc constraint is not fixed, the VALLEY constraint cannot be currently described with the graph-based representation. However, this would not hold anymore if we were introducing a slot that specifies how to merge adjacent vertices of the final graph.

related: ALL_EQUAL_VALLEY, ALL_EQUAL_VALLEY_MIN, DECREASING_VALLEY, INCREASING_VALLEY, NO_PEAK.

specialisation: NO_VALLEY *(the variable counting the number of valleys is set to* 0 *and removed)*.

Keywords

characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint arguments: reverse of a constraint, pure functional dependency.

constraint network structure: sliding cyclic(1) constraint network(2).

filtering: glue matrix.

modelling: functional dependency.

Cond. implications

- VALLEY($\texttt{N}, \texttt{VARIABLES}$)
  with $\texttt{N} > 0$
  implies ATLEAST_NVALUE($\texttt{NVAL}, \texttt{VARIABLES}$)
  when $\texttt{NVAL} = 2$.

- VALLEY(N, VARIABLES)
  implies INFLEXION(N, VARIABLES)
  when N = PEAK(VARIABLES.var) + VALLEY(VARIABLES.var).

Automaton Figure 5.841 depicts the automaton associated with the VALLEY constraint. To each pair of consecutive variables $(\texttt{VAR}_i, \texttt{VAR}_{i+1})$ of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links $\texttt{VAR}_i$, $\texttt{VAR}_{i+1}$ and S_i: $(\texttt{VAR}_i < \texttt{VAR}_{i+1} \Leftrightarrow S_i = 0) \wedge (\texttt{VAR}_i = \texttt{VAR}_{i+1} \Leftrightarrow S_i = 1) \wedge (\texttt{VAR}_i > \texttt{VAR}_{i+1} \Leftrightarrow S_i = 2)$.

STATE SEMANTICS

s	: stationary/increasing mode	$(\{<\mid=\}^*)$
u	: decreasing mode	$(>\{>\mid=\}^*)$

VALLEY$\left(\begin{array}{c}\overrightarrow{\mathtt{N}_5} = 0,\\ \langle 1, 1, 4, 8, 8, 2 \rangle\end{array}\right)$ VALLEY$\left(\begin{array}{c}\overleftarrow{\mathtt{N}_2} = 0,\\ \langle 1, 7, 2 \rangle\end{array}\right)$

glue matrix entry associated with the state pair (u, u):

$\mathtt{N} = \overrightarrow{\mathtt{C}_5} + 1 + \overleftarrow{\mathtt{C}_2} = 0 + 1 + 0 = 1$

Figure 5.844: Illustrating the use of the state pair (u, u) of the glue matrix for linking $\mathtt{N}$ with the counters variables obtained after reading the prefix $1, 1, 4, 8, 8, 2$ and corresponding suffix $2, 7, 1$ of the sequence $1, 1, 4, 8, 8, 2, 7, 1$; note that the suffix $2, 7, 1$ (in pink) is proceed in reverse order; the left (resp. right) table shows the initialisation (for $i = 0$) and the evolution (for $i > 0$) of the state of the automaton and its counter C upon reading the prefix $1, 1, 4, 8, 8, 2$ (resp. the reverse suffix $1, 7, 2$).

5.426 VEC_EQ_TUPLE

► ▷ ◁ ◄ DESCRIPTION LINKS GRAPH

Origin Used for defining IN_RELATION.

Constraint VEC_EQ_TUPLE(VARIABLES, TUPLE)

Arguments

VARIABLES	:	collection(var−dvar)
TUPLE	:	collection(val−int)

Restrictions

required(VARIABLES, var)
required(TUPLE, val)
$|\text{VARIABLES}| = |\text{TUPLE}|$

Purpose Enforce a vector of domain variables to be equal to a tuple of values.

Example $(\langle 5, 3, 3\rangle, \langle 5, 3, 3\rangle)$

The VEC_EQ_TUPLE constraint holds since the first, the second and the third items of VARIABLES $= \langle 5, 3, 3\rangle$ are respectively equal to the first, the second and the third items of TUPLE $= \langle 5, 3, 3\rangle$.

Typical

$|\text{VARIABLES}| > 1$
range(VARIABLES.var) > 1
range(TUPLE.val) > 1

Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES, TUPLE).
- Items of VARIABLES and TUPLE are permutable (*same permutation used*).

Arg. properties Contractible wrt. VARIABLES and TUPLE (*remove items from same position*).

Used in IN_RELATION.

See also **generalisation:** LEX_EQUAL *(*integer *replaced by* variable *in second argument)*.

implies: LEX_EQUAL.

Keywords **characteristic of a constraint:** tuple.

constraint type: value constraint.

filtering: arc-consistency.

Arc input(s)	VARIABLES TUPLE
Arc generator	$PRODUCT(=) \mapsto$ collection(variables, tuple)
Arc arity	2
Arc constraint(s)	variables.var = tuple.val
Graph property(ies)	**NARC**= |VARIABLES|

Graph model Parts (A) and (B) of Figure 5.845 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

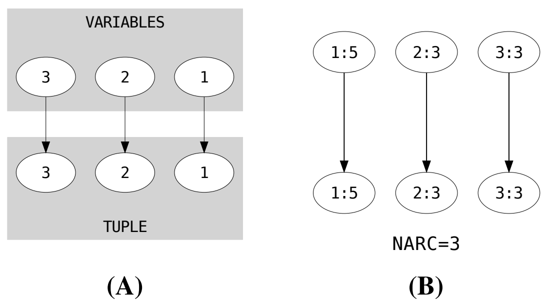

Figure 5.845: Initial and final graph of the VEC_EQ_TUPLE constraint

Signature Since we use the arc generator $PRODUCT(=)$ on the collections VARIABLES and TUPLE, and because of the restriction |VARIABLES| = |TUPLE|, the maximum number of arcs of the final graph is equal to |VARIABLES|. Therefore we can rewrite the graph property **NARC** = |VARIABLES| to **NARC** ≥ |VARIABLES| and simplify $\underline{\mathbf{NARC}}$ to $\overline{\mathbf{NARC}}$.

5.427 VISIBLE

▶ ▷ ◁ ◀

DESCRIPTION LINKS

$\texttt{OBJECTS.oid} \geq 1$
$\texttt{OBJECTS.oid} \leq |\texttt{OBJECTS}|$
$\texttt{OBJECTS.sid} \geq 1$
$\texttt{OBJECTS.sid} \leq |\texttt{SBOXES}|$
$\texttt{OBJECTS.duration} \geq 0$
$|\texttt{SBOXES}| \geq 1$
$\texttt{required}(\texttt{SBOXES}, [\texttt{sid}, \texttt{t}, \texttt{l}])$
$\texttt{SBOXES.sid} \geq 1$
$\texttt{SBOXES.sid} \leq |\texttt{SBOXES}|$
$\texttt{do\_not\_overlap}(\texttt{SBOXES})$

Purpose

Holds if and only if:

1. The difference between the end in time and the start in time of each object is equal to its duration in time.
2. Given a collection of potential observations places FROM, where each observation place is specified by a *dimension* (i.e., an integer between 0 and $k-1$) and by a *direction* (i.e., an integer between 0 and 1), and given for each shifted box of SBOXES a set of visible faces, enforce that *at least one visible face of each shifted box associated with an object* $o \in$ OBJECTS *should be entirely visible from at least one observation place of* FROM *at time* o.start *as well as at time* o.end -1. This notion is defined in a more formal way in the **Remark** slot.

Example

$$\left(\begin{array}{l} 2,\{0,1\}, \\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \left\langle \begin{array}{llllll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 1,2\rangle & \texttt{s}-8 & \texttt{d}-8 & \texttt{e}-16, \\ \texttt{oid}-2 & \texttt{sid}-2 & \texttt{x}-\langle 4,2\rangle & \texttt{s}-1 & \texttt{d}-15 & \texttt{e}-16 \end{array}\right\rangle, \\ \left\langle \begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,3\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$

$$\left(\begin{array}{l} 2,\{0,1\}, \\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \left\langle \begin{array}{llllll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 4,1\rangle & \texttt{s}-1 & \texttt{d}-8 & \texttt{e}-9, \\ \texttt{oid}-2 & \texttt{sid}-2 & \texttt{x}-\langle 1,2\rangle & \texttt{s}-1 & \texttt{d}-15 & \texttt{e}-16 \end{array}\right\rangle, \\ \left\langle \begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,3\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$

$$\left(\begin{array}{l} 2,\{0\}, \\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \left\langle \begin{array}{llllll} \texttt{oid}-1 & \texttt{sid}-1 & \texttt{x}-\langle 2,1\rangle & \texttt{s}-1 & \texttt{d}-8 & \texttt{e}-9, \\ \texttt{oid}-2 & \texttt{sid}-2 & \texttt{x}-\langle 4,3\rangle & \texttt{s}-1 & \texttt{d}-15 & \texttt{e}-16 \end{array}\right\rangle, \\ \left\langle \begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$

(`s` for `start`, `d` for `duration`, `e` for `end`)

The five previous examples correspond respectively to parts (I), (II) of Figure 5.847, to parts (III) and (IV) of Figure 5.848, and to Figure 5.849. Before introducing these five examples Figure 5.846 first illustrates the notion of *observations places* and of *visible faces*.

We first need to introduce a number of definitions in order to illustrate the notion of *visibility*.

Definition 1. *Consider two distinct objects o and o' of the* VISIBLE *constraint (i.e., $o, o' \in$ iobjects) as well as an observation place defined by the pair $\langle \texttt{dim}, \texttt{dir}\rangle \in$ `FROM`. The object o* is masked by *the object o' according to the observation place $\langle \texttt{dim}, \texttt{dir}\rangle$ if there exist two shifted boxes s and s' respectively associated with o and o' such that conditions* **A**, **B**, **C**, **D** *and* **E** *all hold:*

- *(**A**) $o.\texttt{duration} > 0 \wedge o'.\texttt{duration} > 0 \wedge o.\texttt{end} > o'.\texttt{start} \wedge o'.\texttt{end} > o.\texttt{start}$ (i.e., the time intervals associated with o and o' intersect).*
- *(**B**) Discarding dimension `dim`, s and s' intersect in all dimensions specified by `DIMS` (i.e., objects o and o' are in vis-à-vis).*

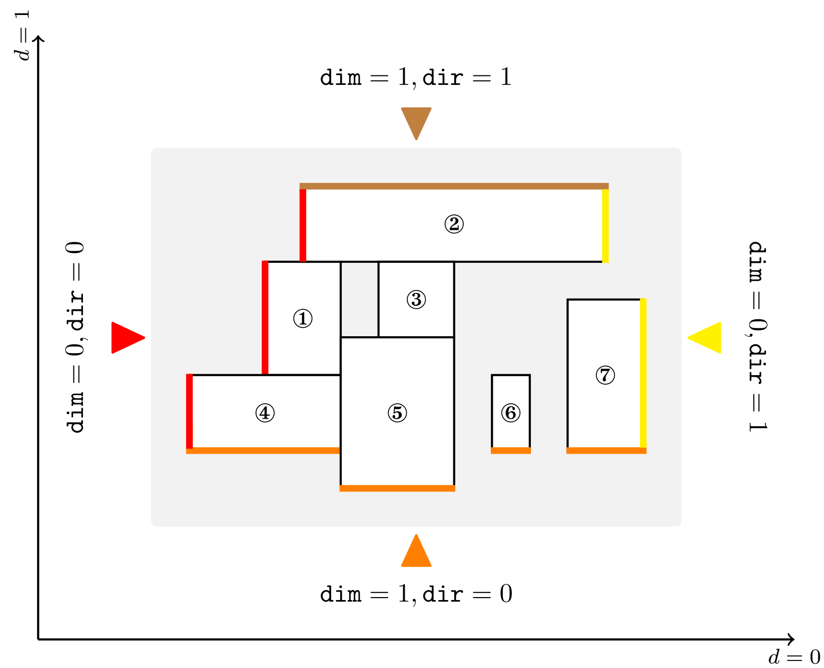

Figure 5.846: Entirely visible faces (depicted by a thick line) of rectangles ①, ②, ③, ④, ⑤, ⑥ and ⑦ from the four observation places $\langle \mathtt{dim}=0, \mathtt{dir}=1\rangle$, $\langle \mathtt{dim}=0, \mathtt{dir}=0\rangle$, $\langle \mathtt{dim}=1, \mathtt{dir}=1\rangle$ and $\langle \mathtt{dim}=1, \mathtt{dir}=0\rangle$ (depicted by a small triangle)

- *(**C**) If* $\mathtt{dir}=0$
  then $o.x[\mathtt{dim}] + s.t[\mathtt{dim}] \geq o'.x[\mathtt{dim}] + s'.t[\mathtt{dim}] + s'.l[\mathtt{dim}]$
  else $o'.x[\mathtt{dim}] + s'.t[\mathtt{dim}] \geq o.x[\mathtt{dim}] + s.t[\mathtt{dim}] + s.l[\mathtt{dim}]$ *(i.e., in dimension* dim*, o and o' are ordered in the wrong way according to direction* dir*).*
- *(**D**)* $o.\mathtt{start} > o'.\mathtt{start} \vee o.\mathtt{end} < o'.\mathtt{end}$ *(i.e., instants* $o.\mathtt{start}$ *or* $o.\mathtt{end}$ *are located within interval* $[o'.\mathtt{start}, o'.\mathtt{end}]$*; we consider also condition **A**.).*
- *(**E**) The observation place* $\langle \mathtt{dim}, \mathtt{dir}\rangle$ *occurs within the list of visible faces associated with the face attribute* f *of the shifted box s (i.e., the pair* $\langle \mathtt{dim}, \mathtt{dir}\rangle$ *is a potentially visible face of o).*

Definition 2. *Consider an object o of the collection* OBJECTS *as well as a possible observation place defined by the pair* $\langle \mathtt{dim}, \mathtt{dir}\rangle$*. The object o* is masked according to the observation place $\langle \mathtt{dim}, \mathtt{dir}\rangle$ *if and only if at least one of the following conditions holds:*

- *No shifted box associated with o has the pair* $\langle \mathtt{dim}, \mathtt{dir}\rangle$ *as one of its potentially visible face.*
- *The object o is masked according to the possible observation place* $\langle \mathtt{dim}, \mathtt{dir}\rangle$ *by another object o'.*

Figures 5.847, 5.848, and 5.849 respectively illustrate Definition 1 in the context of an observation place (depicted by a triangle) that is equal to the pair $\langle \mathtt{dim}=0, \mathtt{dir}=1\rangle$. Note that, in the context of Figure 5.849, as the DIMS parameter of the VISIBLE constraint only mentions dimension 0 (and not dimension 1), one object may be masked by another object even though the two objects do not intersect in any dimension: i.e., only their respective ordering in the dimension $\mathtt{dim} = 0$ as well as their positions in time matter.

Definition 3. *Consider an object o of the collection* OBJECTS *as well as a possible observation place defined by the pair $\langle \mathtt{dim}, \mathtt{dir} \rangle$. The object o* is masked according to the observation place $\langle \mathtt{dim}, \mathtt{dir} \rangle$ *if and only if at least one of the following conditions holds:*

- *No shifted box associated with o has the pair $\langle \mathtt{dim}, \mathtt{dir} \rangle$ as one of its potentially visible face.*
- *The object o is masked according to the possible observation place $\langle \mathtt{dim}, \mathtt{dir} \rangle$ by another object o'.*

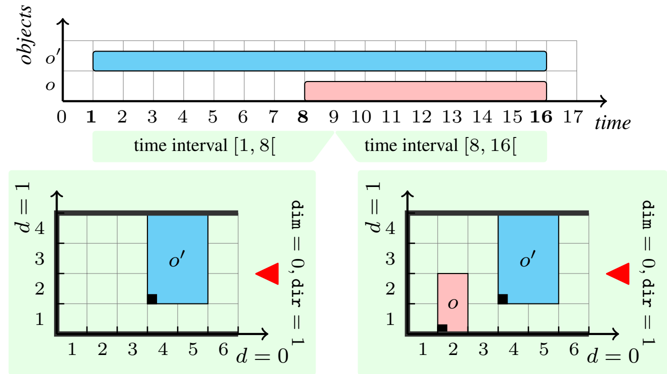
Definition 4. *An object of the collection* OBJECTS *constraint is* masked according to a set of possible observation places FROM *if it is masked according to each observation place of* FROM.

We are now in position to define the VISIBLE constraint.

Definition 5. *Given a* VISIBLE(K, DIMS, FROM, OBJECTS, SBOXES) *constraint, the* VISIBLE *constraint holds if none of the objects of* OBJECTS *is masked according to the dimensions of* DIMS *and to the set of possible observation places defined by* FROM.

$$\texttt{VISIBLE}\left(\begin{array}{c} 2,\ \{0,1\},\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \left\langle\begin{array}{llllll} \texttt{oid}-o & \texttt{sid}-1 & \texttt{x}-\langle 1,2\rangle & \texttt{start}-8 & \texttt{duration}-8 & \texttt{end}-16, \\ \texttt{oid}-o' & \texttt{sid}-2 & \texttt{x}-\langle 4,2\rangle & \texttt{start}-1 & \texttt{duration}-15 & \texttt{end}-16 \end{array}\right\rangle, \\ \left\langle\begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,3\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$

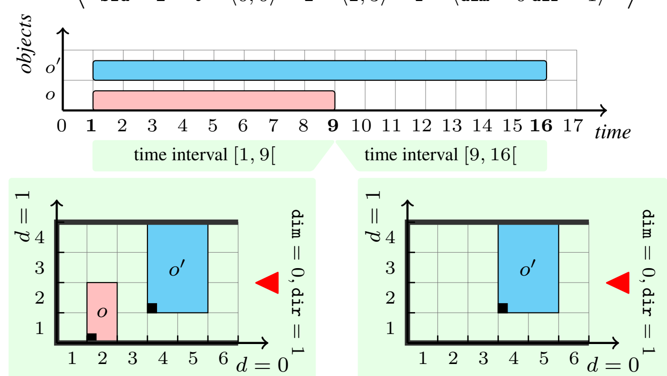
(I)



o is masked by o' according to $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ since:
(A) o and o' intersect in time,
(B) o and o' intersect in dimension 1,
(C) in dimension 0, o' starts after the end of o,
(D) the start in time of o is located after the start in time of o',
(E) $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ is a potentially visible face of o.

$$\texttt{VISIBLE}\left(\begin{array}{c} 2,\ \{0,1\},\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \left\langle\begin{array}{llllll} \texttt{oid}-o & \texttt{sid}-1 & \texttt{x}-\langle 1,2\rangle & \texttt{start}-1 & \texttt{duration}-8 & \texttt{end}-9, \\ \texttt{oid}-o' & \texttt{sid}-2 & \texttt{x}-\langle 4,2\rangle & \texttt{start}-1 & \texttt{duration}-15 & \texttt{end}-16 \end{array}\right\rangle, \\ \left\langle\begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,3\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$

(II)

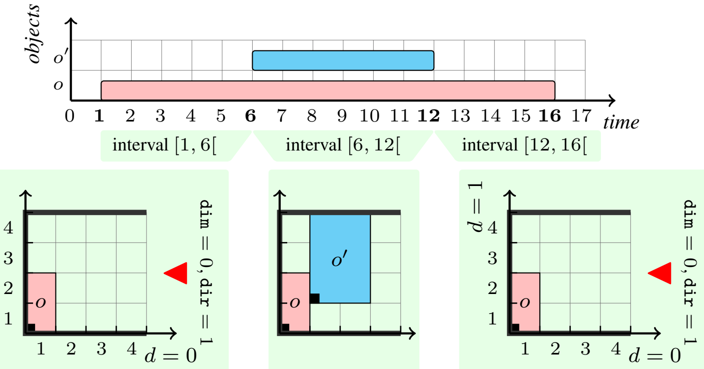


o is masked by o' according to $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ since:
(A) o and o' intersect in time,
(B) o and o' intersect in dimension 1,
(C) in dimension 0, o' starts after the end of o,
(D) the end in time of o is located before the end in time of o',
(E) $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ is a potentially visible face of o.

Figure 5.847: Illustration of Definition 1: two examples (I) and (II) where an object o is masked by an object o' according to dimensions $\{0,1\}$ and to the observation place $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ because **(A)** o and o' intersect in time, **(B)** o and o' intersect in dimension 1, **(C)** o and o' are not well ordered according to the observation place, **(D)** there exists an instant where o' if present (but not o) and **(E)** $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ is a potentially visible face of o.

$$\text{VISIBLE}\left(\begin{array}{c} 2,\ \{0,1\},\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle,\\ \left\langle\begin{array}{llllll} \texttt{oid}-o & \texttt{sid}-1 & \texttt{x}-\langle 1,1\rangle & \texttt{start}-1 & \texttt{duration}-15 & \texttt{end}-16,\\ \texttt{oid}-o' & \texttt{sid}-2 & \texttt{x}-\langle 2,2\rangle & \texttt{start}-6 & \texttt{duration}-6 & \texttt{end}-12\end{array}\right\rangle,\\ \left\langle\begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle,\\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,3\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle\end{array}\right\rangle\end{array}\right)$$

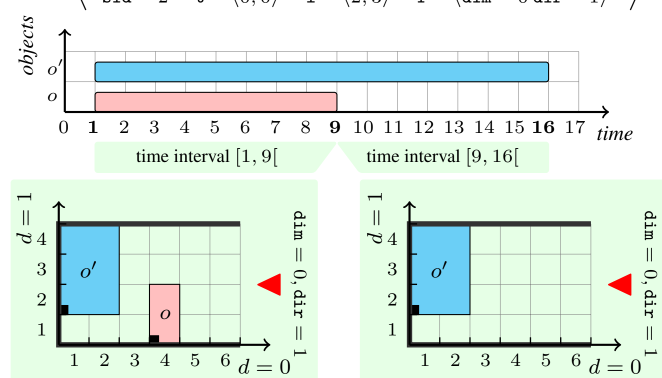
(III)



o is not masked by o' according to $\langle\texttt{dim}=0,\texttt{dir}=1\rangle$ since:
(A) Even though o and o' intersect in time,
(B) and even though o and o' intersect in dimension 1,
(C) and even though, in dimension 0, o' starts after the end of o,
(E) and even though $\langle\texttt{dim}=0,\texttt{dir}=1\rangle$ is a potentially visible face of o, condition **(D)** does not hold.

$$\text{VISIBLE}\left(\begin{array}{c} 2,\ \{0,1\},\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle,\\ \left\langle\begin{array}{llllll} \texttt{oid}-o & \texttt{sid}-1 & \texttt{x}-\langle 4,1\rangle & \texttt{start}-1 & \texttt{duration}-8 & \texttt{end}-9,\\ \texttt{oid}-o' & \texttt{sid}-2 & \texttt{x}-\langle 1,2\rangle & \texttt{start}-1 & \texttt{duration}-15 & \texttt{end}-16\end{array}\right\rangle,\\ \left\langle\begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle,\\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,3\rangle & \texttt{f}-\langle \texttt{dim}-0\ \texttt{dir}-1\rangle\end{array}\right\rangle\end{array}\right)$$

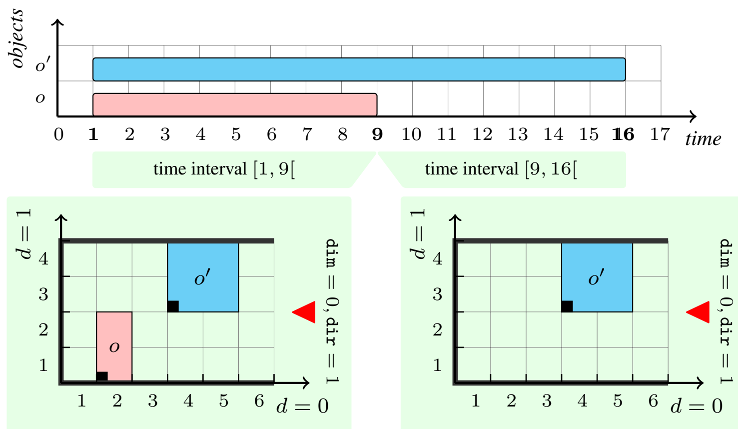
(IV)



o is not masked by o' according to $\langle\texttt{dim}=0,\texttt{dir}=1\rangle$ since:
(A) Even though o and o' intersect in time,
(B) and even though o and o' intersect in dimension 1, and even
(D) though the end in time of o is located before the end in time of o',
(E) and even though $\langle\texttt{dim}=0,\texttt{dir}=1\rangle$ is a potentially visible face of o, condition **(C)** does not hold.

Figure 5.848: Illustration of Definition 1: two examples (III) and (IV) where an object o is not masked by an object o' according to the observation place $\langle\texttt{dim}=0,\texttt{dir}=1\rangle$.

$$\text{VISIBLE}\left(\begin{array}{c} 2,\ \{0\},\ \langle \texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \left\langle\begin{array}{llllll} \texttt{oid}-o & \texttt{sid}-1 & \texttt{x}-\langle 2,1\rangle & \texttt{start}-1 & \texttt{duration}-8 & \texttt{end}-9, \\ \texttt{oid}-o' & \texttt{sid}-2 & \texttt{x}-\langle 4,3\rangle & \texttt{start}-1 & \texttt{duration}-15 & \texttt{end}-16 \end{array}\right\rangle, \\ \left\langle\begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 1,2\rangle & \texttt{f}-\langle\texttt{dim}-0\ \texttt{dir}-1\rangle, \\ \texttt{sid}-2 & \texttt{t}-\langle 0,0\rangle & \texttt{l}-\langle 2,2\rangle & \texttt{f}-\langle\texttt{dim}-0\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$



o is masked by o' according to $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ since:

A. o and o' intersect in time,

B. in dimension 0, o' starts after the end of o,

C. the end in time of o is located before the end in time of o',

D. $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ is a potentially visible face of o.

Figure 5.849: Illustration of Definition 1: the case where an object o is masked by an object o' according to dimension 0 and to the observation place $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ because: **(A)** o and o' intersect in time, **(C)** o and o' are not well ordered according to the observation place and **(D)** there exists an instant where o' if present (but not o) and **(E)** $\langle \texttt{dim}=0, \texttt{dir}=1\rangle$ is a potentially visible face of o.

Typical $|\texttt{OBJECTS}| > 1$

Symmetries

- Items of `OBJECTS` are permutable.
- Items of `SBOXES` are permutable.

Usage We now give several typical concrete uses of the VISIBLE constraint, which all mention the DIFFST as well as the VISIBLE constraints:

- Figure 5.850 corresponds to a *ship loading problem* where containers are piled within a ship by a crane each time the ship visits a given harbour. In this context we have first to express the fact that *a container can only be placed on top of an already placed container* and second, that *a container can only be taken away if no container is placed on top of it*. These two conditions are expressed by a single VISIBLE constraint for which the `DIMS` parameter mentions all three dimensions of the placement space and the `FROM` parameter mentions the pair $\langle \texttt{dim} = 2, \texttt{dir} = 1\rangle$ as its unique observation place. In addition we also use a DIFFST constraint for expressing non-overlapping.

$$\text{VISIBLE}\left(\begin{array}{c} 3,\ \{0,1,2\},\ \langle \texttt{dim}-2\ \texttt{dir}-1\rangle, \\ \left\langle \begin{array}{llllll} \texttt{oid}-\mathbf{1} & \texttt{sid}-1 & \texttt{x}-\langle 1,1,1\rangle & \texttt{start}-0 & \texttt{duration}-17 & \texttt{end}-17, \\ \texttt{oid}-\mathbf{2} & \texttt{sid}-1 & \texttt{x}-\langle 1,1,3\rangle & \texttt{start}-0 & \texttt{duration}-8 & \texttt{end}-8, \\ \texttt{oid}-\mathbf{3} & \texttt{sid}-1 & \texttt{x}-\langle 4,1,1\rangle & \texttt{start}-0 & \texttt{duration}-8 & \texttt{end}-8, \\ \texttt{oid}-\mathbf{4} & \texttt{sid}-1 & \texttt{x}-\langle 1,1,3\rangle & \texttt{start}-8 & \texttt{duration}-9 & \texttt{end}-17, \\ \texttt{oid}-\mathbf{5} & \texttt{sid}-1 & \texttt{x}-\langle 4,1,1\rangle & \texttt{start}-8 & \texttt{duration}-16 & \texttt{end}-24, \\ \texttt{oid}-\mathbf{6} & \texttt{sid}-1 & \texttt{x}-\langle 1,1,1\rangle & \texttt{start}-17 & \texttt{duration}-7 & \texttt{end}-24 \end{array}\right\rangle, \\ \langle\ \texttt{sid}-1\quad \texttt{t}-\langle 0,0,0\rangle\quad \texttt{l}-\langle 2,4,2\rangle\quad \texttt{f}-\langle \texttt{dim}-2\ \texttt{dir}-1\rangle\ \rangle \end{array}\right)$$

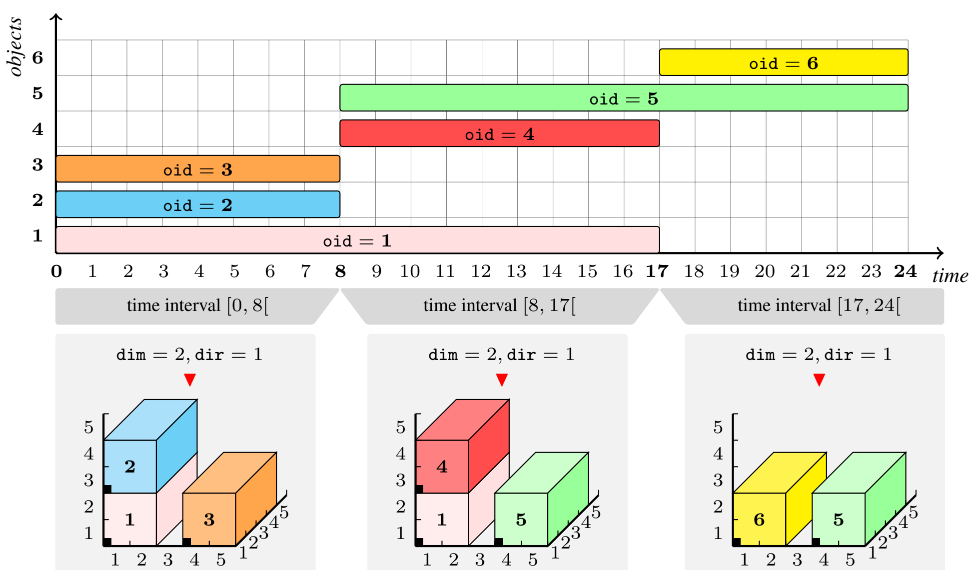


Figure 5.850: Illustration of the ship loading problem

- Figure 5.851 corresponds to a *container loading/unloading problem* in the context of a pick-up delivery problem where the loading/unloading takes place with respect to the front door of the container. Beside the DIFFST constraint used for expressing non-overlapping, we use two distinct VISIBLE constraints:

  - The first VISIBLE constraint takes care of the location of the front door of the container (each object o has to be loaded/unloaded without moving around any other object, i.e., objects that are in the vis-à-vis of o according to the front door of the container). This is expressed by a single VISIBLE constraint for which the DIMS parameter mentions all three dimensions of the placement space and the FROM parameter mentions the pair $\langle \texttt{dim} = 1, \texttt{dir} = 0 \rangle$ as its unique observation place.
  - The second VISIBLE constraint takes care of the *gravity dimension* (i.e., each object that has to be loaded should not be put under another object, and reciprocally each object that has to be unloaded should not be located under another object). This is expressed by the same VISIBLE constraint that was used for the ship loading problem, i.e., a VISIBLE constraint for which the DIMS parameter mentions all three dimensions of the placement space and the FROM parameter mentions the pair $\langle \texttt{dim} = 2, \texttt{dir} = 1 \rangle$ as its unique observation place.

- Figure 5.852 corresponds to a *pallet loading problem* where one has to place six objects on a pallet. Each object corresponds to a parallelepiped that has a bar code on one of its four sides (i.e., the sides that are different from the top and the bottom of the parallelepiped). If, for some reason, an object has no bar code then we simply remove it from the objects that will be passed to the VISIBLE constraint: this is the case, for example, for the sixth object. In this context the constraint to enforce (beside the non-overlapping constraint between the parallelepipeds that are assigned to a same pallet) is the fact that the bar code of each object should be visible (i.e., visible from one of the four sides of the pallet). This is expressed by the VISIBLE constraint given in Part (F) of Figure 5.852.

Remark The VISIBLE constraint is a generalisation of the ACCESSIBILITY constraint initially introduced in the context of the DIFFN constraint.

See also **common keyword:** DIFFN *(geometrical constraint)*, GEOST, GEOST_TIME *(geometrical constraint,sweep)*, NON_OVERLAP_SBOXES *(geometrical constraint)*.

Keywords **constraint type:** decomposition, predefined constraint.

filtering: sweep.

geometry: geometrical constraint.

$$\text{VISIBLE}\left(\begin{array}{c} 3,\ \{0,1,2\},\ \langle \texttt{dim}-1\ \texttt{dir}-0\rangle,\\ \left\langle\begin{array}{llllll} \texttt{oid}-\mathbf{1} & \texttt{sid}-1 & \texttt{x}-\langle 1,2,3\rangle & \texttt{start}-0 & \texttt{duration}-8 & \texttt{end}-8,\\ \texttt{oid}-\mathbf{2} & \texttt{sid}-2 & \texttt{x}-\langle 1,3,3\rangle & \texttt{start}-0 & \texttt{duration}-8 & \texttt{end}-8,\\ \texttt{oid}-\mathbf{3} & \texttt{sid}-3 & \texttt{x}-\langle 1,1,1\rangle & \texttt{start}-0 & \texttt{duration}-17 & \texttt{end}-17,\\ \texttt{oid}-\mathbf{4} & \texttt{sid}-4 & \texttt{x}-\langle 4,1,1\rangle & \texttt{start}-0 & \texttt{duration}-17 & \texttt{end}-17,\\ \texttt{oid}-\mathbf{5} & \texttt{sid}-5 & \texttt{x}-\langle 1,2,3\rangle & \texttt{start}-8 & \texttt{duration}-9 & \texttt{end}-17,\\ \texttt{oid}-\mathbf{6} & \texttt{sid}-6 & \texttt{x}-\langle 3,1,1\rangle & \texttt{start}-8 & \texttt{duration}-12 & \texttt{end}-24,\\ \texttt{oid}-\mathbf{7} & \texttt{sid}-3 & \texttt{x}-\langle 1,1,1\rangle & \texttt{start}-17 & \texttt{duration}-7 & \texttt{end}-24 \end{array}\right\rangle,\\ \left\langle\begin{array}{llll} \texttt{sid}-1 & \texttt{t}-\langle 0,0,0\rangle & \texttt{l}-\langle 2,1,1\rangle & \texttt{f}-\langle \texttt{dim}-1\ \texttt{dir}-0,\ \texttt{dim}-2\ \texttt{dir}-1\rangle,\\ \texttt{sid}-2 & \texttt{t}-\langle 0,0,0\rangle & \texttt{l}-\langle 2,2,2\rangle & \texttt{f}-\langle \texttt{dim}-1\ \texttt{dir}-0,\ \texttt{dim}-2\ \texttt{dir}-1\rangle,\\ \texttt{sid}-3 & \texttt{t}-\langle 0,0,0\rangle & \texttt{l}-\langle 2,4,2\rangle & \texttt{f}-\langle \texttt{dim}-1\ \texttt{dir}-0,\ \texttt{dim}-2\ \texttt{dir}-1\rangle,\\ \texttt{sid}-4 & \texttt{t}-\langle 0,0,0\rangle & \texttt{l}-\langle 2,4,1\rangle & \texttt{f}-\langle \texttt{dim}-1\ \texttt{dir}-0,\ \texttt{dim}-2\ \texttt{dir}-1\rangle,\\ \texttt{sid}-5 & \texttt{t}-\langle 0,0,0\rangle & \texttt{l}-\langle 2,3,1\rangle & \texttt{f}-\langle \texttt{dim}-1\ \texttt{dir}-0,\ \texttt{dim}-2\ \texttt{dir}-1\rangle,\\ \texttt{sid}-6 & \texttt{t}-\langle 0,0,0\rangle & \texttt{l}-\langle 1,2,2\rangle & \texttt{f}-\langle \texttt{dim}-1\ \texttt{dir}-0,\ \texttt{dim}-2\ \texttt{dir}-1\rangle \end{array}\right\rangle \end{array}\right)$$

5.428 WEIGHTED_PARTIAL_ALLDIFF

DESCRIPTION LINKS GRAPH

Origin [417, page 71]

Constraint WEIGHTED_PARTIAL_ALLDIFF(VARIABLES, UNDEFINED, VALUES, COST)

Synonyms WEIGHTED_PARTIAL_ALLDIFFERENT, WEIGHTED_PARTIAL_ALLDISTINCT, WPA.

Arguments

VARIABLES	:	collection(var−dvar)
UNDEFINED	:	int
VALUES	:	collection(val−int, weight−int)
COST	:	dvar

Restrictions

required(VARIABLES, var)
|VALUES| > 0
required(VALUES, [val, weight])
in_attr(VARIABLES, var, VALUES, val)
distinct(VALUES, val)

Purpose All variables of the VARIABLES collection that are not assigned to value UNDEFINED must have pairwise distinct values from the val attribute of the VALUES collection. In addition COST is the sum of the weight attributes associated with the values assigned to the variables of VARIABLES. Within the VALUES collection, value UNDEFINED must be explicitly defined with a weight of 0.

Example

$$\left(\begin{array}{l}\langle 4,0,1,2,0,0\rangle, 0, \\ \left\langle\begin{array}{ll}\texttt{val}-0 & \texttt{weight}-0, \\ \texttt{val}-1 & \texttt{weight}-2, \\ \texttt{val}-2 & \texttt{weight}-{-1}, \\ \texttt{val}-4 & \texttt{weight}-7, \\ \texttt{val}-5 & \texttt{weight}-{-8}, \\ \texttt{val}-6 & \texttt{weight}-2\end{array}\right\rangle, 8\end{array}\right)$$

The WEIGHTED_PARTIAL_ALLDIFF constraint holds since:

- No value, except value UNDEFINED $= 0$, is used more than once.
- COST $= 8$ is equal to the sum of the weights 2, -1 and 7 of the values 1, 2 and 4 assigned to the variables of VARIABLES $= \langle 4, 0, 1, 2, 0, 0\rangle$.

Typical

|VARIABLES| > 0
ATLEAST(1, VARIABLES, UNDEFINED)
|VARIABLES| ≤ |VALUES| + 2

Symmetries

- Items of VARIABLES are permutable.
- Items of VALUES are permutable.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val that are both different from UNDEFINED can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val that is different from UNDEFINED can be renamed to any unused value that is also different from UNDEFINED.

Arg. properties

Functional dependency: COST determined by VARIABLES and VALUES.

Usage

In his PhD thesis [417, pages 71–72], Sven Thiel describes the following three potential scenarios of the WEIGHTED_PARTIAL_ALLDIFF constraint:

- Given a set of tasks (i.e., the items of the VARIABLES collection), assign to each task a resource (i.e., an item of the VALUES collection). Except for the resource associated with value UNDEFINED, every resource can be used at most once. The cost of a resource is independent from the task to which the resource is assigned. The cost of value UNDEFINED is equal to 0. The total cost COST of an assignment corresponds to the sum of the costs of the resources effectively assigned to the tasks. Finally we impose an upper bound on the total cost.
- Given a set of persons (i.e., the items of the VARIABLES collection), select for each person an offer (i.e., an item of the VALUES collection). Except for the offer associated with value UNDEFINED, every offer should be selected at most once. The profit associated with an offer is independent from the person that selects the offer. The profit of value UNDEFINED is equal to 0. The total benefit COST is equal to the sum of the profits of the offers effectively selected. In addition we impose a lower bound on the total benefit.
- The last scenario deals with an application to an over-constraint problem involving the ALLDIFFERENT constraint. Allowing some variables to take an ”undefined” value is done by setting all weights of all the values different from UNDEFINED to 1. As a consequence all variables assigned to a value different from UNDEFINED will have to take distinct values. The COST variable allows one to control the number of such variables.

Remark

It was shown in [417, page 104] that, finding out whether the WEIGHTED_PARTIAL_ALLDIFF constraint has a solution or not is NP-hard. This was achieved by reduction from subset sum.

Algorithm

A filtering algorithm is given in [417, pages 73–104]. After showing that, deciding whether the WEIGHTED_PARTIAL_ALLDIFF has a solution is NP-complete, [417, pages 105–106] gives the following results of his filtering algorithm with respect to consistency under the 3 scenarios previously described:

- For scenario 1, if there is no restriction of the lower bound of the COST variable, the filtering algorithm achieves arc-consistency for all variables of the VARIABLES collection (but not for the COST variable itself).
- For scenario 2, if there is no restriction of the upper bound of the COST variable, the filtering algorithm achieves arc-consistency for all variables of the VARIABLES collection (but not for the COST variable itself).

- Finally, for scenario 3, the filtering algorithm achieves arc-consistency for all variables of the VARIABLES collection as well as for the COST variable.

5.429 XOR

▶ ▷ ◁ ◀ DESCRIPTION LINKS AUTOMATON

Origin Logic

Constraint XOR(VAR, VARIABLES)

Synonyms ODD, REL.

Arguments

VAR : dvar
VARIABLES : collection(var−dvar)

Restrictions

VAR ≥ 0
VAR ≤ 1
$|$VARIABLES$| = 2$
required(VARIABLES, var)
VARIABLES.var ≥ 0
VARIABLES.var ≤ 1

Purpose

Let VARIABLES be a collection of 0-1 variables $\text{VAR}_1, \text{VAR}_2$. Enforce $\text{VAR} = (\text{VAR}_1 \neq \text{VAR}_2)$.

Example

$(0, \langle 0, 0\rangle)$
$(1, \langle 0, 1\rangle)$
$(1, \langle 1, 0\rangle)$
$(0, \langle 1, 1\rangle)$

Symmetry Items of VARIABLES are permutable.

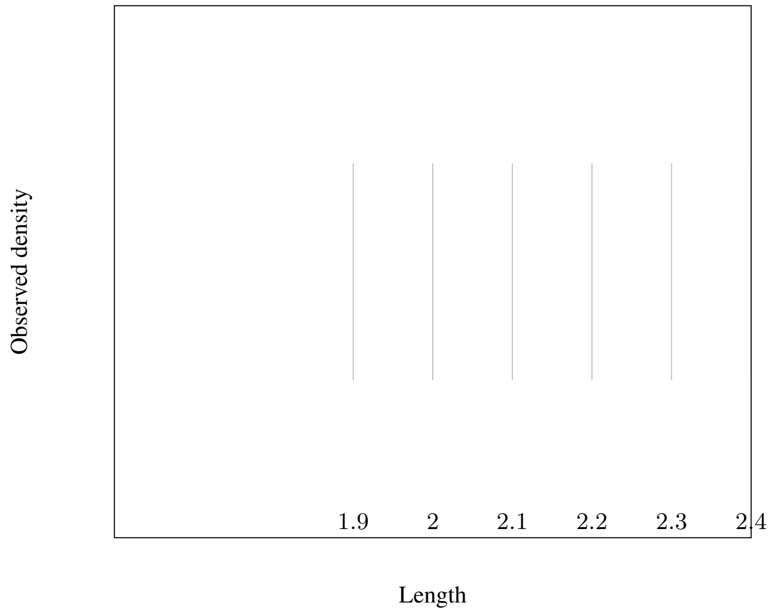
Arg. properties Functional dependency: VAR determined by VARIABLES.

Counting

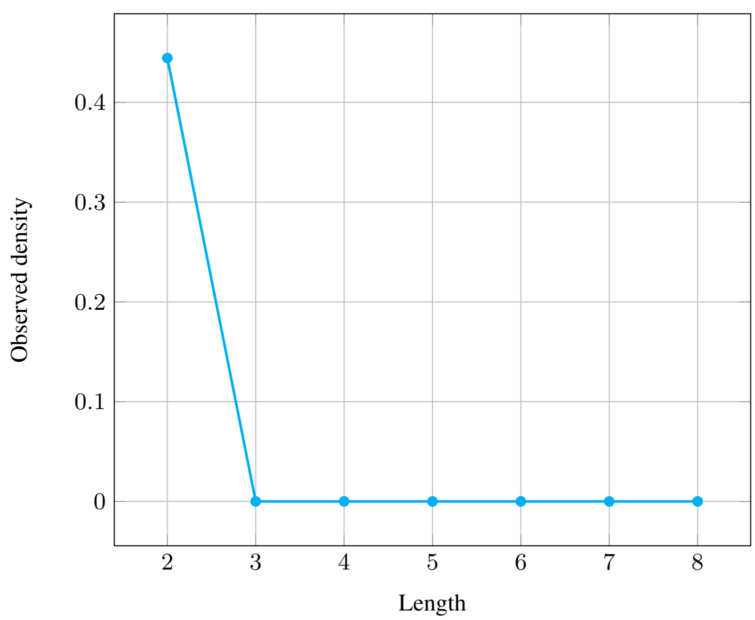
Length (n)	2	3	4	5	6	7	8
Solutions	4	0	0	0	0	0	0

Number of solutions for XOR: domains $0..n$

Solution density for XOR

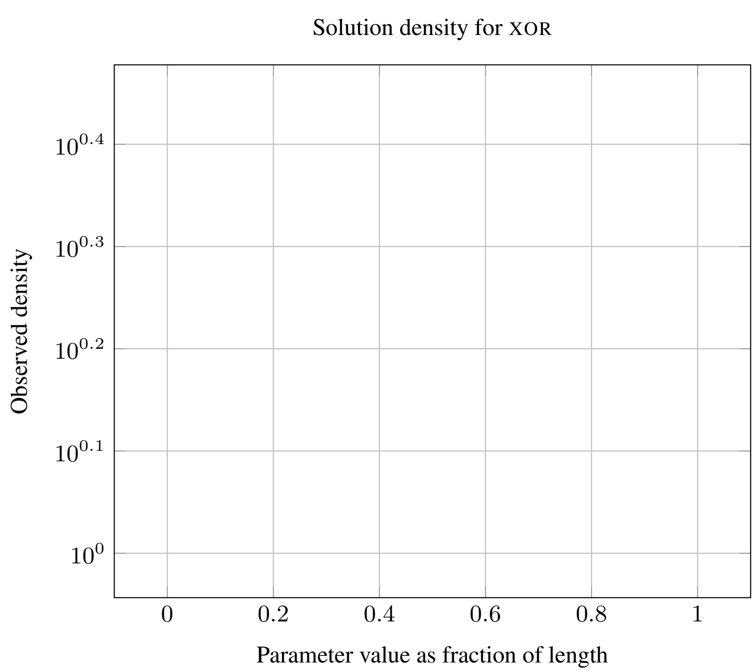


Solution density for XOR

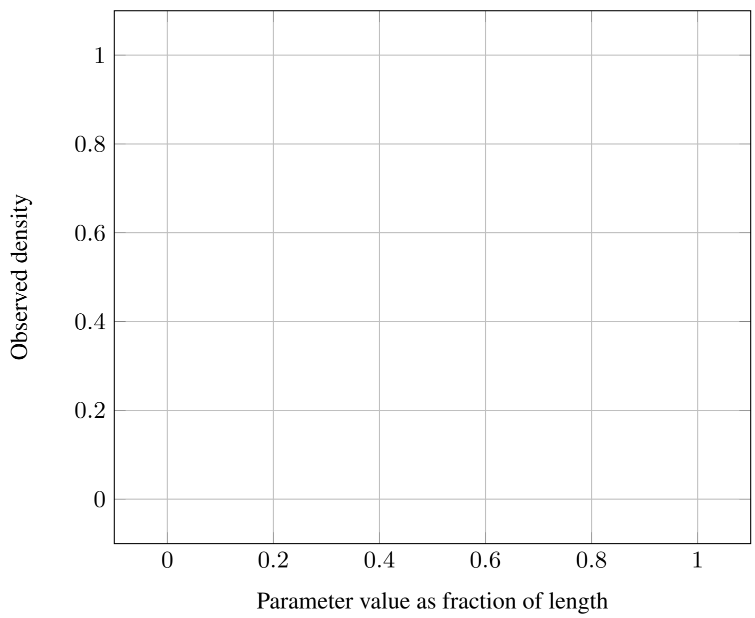


Length (n)		2
Total		4
Parameter value	0	2
	1	2

Solution count for XOR: domains $0..n$



Solution density for XOR



Systems REIFIEDXOR in **Choco**, REL in **Gecode**, XORBOOL in **JaCoP**, #\ in **SICStus**.

See also **common keyword:** AND, EQUIVALENT, IMPLY, NAND, NOR, OR *(Boolean constraint)*.

implies: ATLEAST_NVALUE, SOFT_ALL_EQUAL_MAX_VAR, SOFT_ALL_EQUAL_MIN_VAR.

Keywords **characteristic of a constraint:** automaton, automaton without counters, reified automaton constraint.

constraint arguments: pure functional dependency.

constraint network structure: Berge-acyclic constraint network.

constraint type: Boolean constraint.

filtering: arc-consistency.

modelling: functional dependency.

Automaton Figure 5.854 depicts the automaton associated with the XOR constraint. To the first argument VAR of the XOR constraint corresponds the first signature variable. To each variable $\mathtt{VAR}_i$ of the second argument VARIABLES of the XOR constraint corresponds the next signature variable. There is no signature constraint.

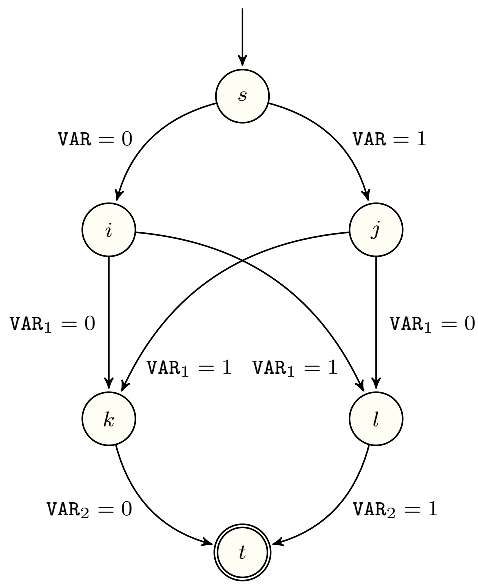


Figure 5.854: Automaton of the XOR constraint

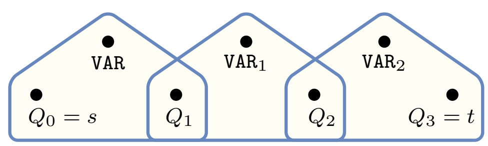

Figure 5.855: Hypergraph of the reformulation corresponding to the automaton of the XOR constraint

5.430 ZERO_OR_NOT_ZERO

► ◁ ◄ DESCRIPTION LINKS

Origin Arithmetic.

Constraint ZERO_OR_NOT_ZERO(VAR1, VAR2)

Synonyms ZEROS_OR_NOT_ZEROS, NOT_ZERO_OR_ZERO, NOT_ZEROS_OR_ZEROS.

Arguments

VAR1	:	dvar
VAR2	:	dvar

Purpose Enforce the fact that either both variables are equal to 0, or both variables are not equal to 0.

Example $(1, 8)$

The ZERO_OR_NOT_ZERO constraint holds since values 1 and 8 are both not equal to zero.

Symmetry Arguments are permutable w.r.t. permutation (VAR1, VAR2).

See also **implied by:** ABS_VALUE, DIVISIBLE_OR, EQ, SIGN_OF.

implies (if swap arguments): ABS_VALUE.

Keywords **constraint arguments:** binary constraint.

constraint type: predefined constraint, arithmetic constraint.

5.431 ZERO_OR_NOT_ZERO_VECTORS

◁ ◀ DESCRIPTION LINKS

Origin Tournament scheduling

Constraint ZERO_OR_NOT_ZERO_VECTORS(VECTORS)

Synonyms ZEROS_OR_NOT_ZEROS_VECTORS, NOT_ZERO_OR_ZERO_VECTORS, NOT_ZEROS_OR_ZEROS_VECTORS.

Type VECTOR : collection(var−dvar)

Argument VECTORS : collection(vec − VECTOR)

Restrictions
|VECTOR| ≥ 1
required(VECTOR, var)
|VECTORS| ≥ 1
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose Given a collection of vectors enforces for each vector that either all its components are equal to 0, or all its components are different from 0. In addition imposes that at least one 0 is used.

Example

$$\left(\left\langle\begin{array}{l}\texttt{vec} - \langle 5,6\rangle,\\ \texttt{vec} - \langle 5,6\rangle,\\ \texttt{vec} - \langle 0,0\rangle,\\ \texttt{vec} - \langle 9,3\rangle,\\ \texttt{vec} - \langle 0,0\rangle\end{array}\right\rangle\right)$$

The ZERO_OR_NOT_ZERO_VECTORS constraint holds since:

- Both components of the first vector $\langle 5,6\rangle$ are different from 0.
- Both components of the second vector $\langle 5,6\rangle$ are different from 0.
- Both components of the third vector $\langle 0,0\rangle$ are equal to 0.
- Both components of the fourth vector $\langle 9,3\rangle$ are different from 0.
- Both components of the fifth vector $\langle 0,0\rangle$ are equal to 0.

Typical
|VECTOR| > 1
|VECTORS| > 1

Arg. properties Contractible wrt. VECTORS.

Keywords **characteristic of a constraint:** vector.
constraint type: predefined constraint, arithmetic constraint.

%% An utility for negating an automaton
%% (WARNING: only valid if everything expressed with ONE SINGLE automaton)
%%
%% negaut(+PosAutomaton, +Alphabet, -NegAutomaton, -AuxConstraint)
%% PosAutomaton: automaton/8 constraint
%% Alphabet: list of atom
%% NegAutomaton: automaton/8 constraint
%% AuxConstraint: constraint
%%
%% Semantics:
%% - (NegAutomaton, AuxConstraint) expresses the negation of PosAutomaton.
%%
%% Synopsis:
```

```
%% - If necessary, add a nonsink state 'fail', and:
%%   * for every letter A of the alphabet: add an arc from 'fail' over
%%     A to 'fail';
%%   * for every state S and letter A of the alphabet, if there is no
%%     outgoing arc from S over A, add an arc from S over A to 'fail'.
%%
%% - If the automaton is counter-free, compute NegAutomaton by swapping
%%   sinks and nonsinks.  AuxConstraint is 'true'.
%%
%% - Otherwise with counters [C1,...,Cn]:
%%   * Suppose that the final counter values are [V1,...,Vn].
%%   * Add a first counter C0 so that C0=0 iff the original automaton
%%     stops in a sink state.
%%   * Convert arcs as follows:
%%       if S2 is sink:
%%        arc(S1,A,S2) --> arc(S1,A,S2,[0,C1,...,Cn])
%%       if S2 is nonsink:
%%        arc(S1,A,S2) --> arc(S1,A,S2,[1,C1,...,Cn])
%%       if S2 is sink:
%%        arc(S1,A,S2,[Y1,...,Yn]) --> arc(S1,A,S2,[0,Y1,...,Yn])
%%       if S2 is nonsink:
%%        arc(S1,A,S2,[Y1,...,Yn]) --> arc(S1,A,S2,[1,Y1,...,Yn])
%%   * The counters for arcs with conditions are augmented similarly.
%%   * For every arc with a condition:
%%        arc(S1,A,_,(P1 -> Q1 ; ... ; Pm -> Qm))
%%     such that (P1 #\/ ... #\/ Pm) could be false, add an arc:
%%        arc(S1,A,fail,((#\P1 #/\ ... #/\ #\Pm) -> [1,C1,...,Cn])
%%   * Conpute NegAutomaton by making all states sinks.
%%   * Let the final counter values of NegAutomaton be [X0,X1,...,Xn].
%%   * AuxConstraint is (X0 #= 1 #\/ X1 #\= V1 #\/ ... #\/ Xn #\= Vn).
