Working version of SICS Technical Report T2012:03
ISSN: 1100-3154

Abstract: This report presents a catalogue of global constraints where each constraint is explicitly described in terms of graph properties and/or automata and/or first order logical formulae with arithmetic. When available, it also presents some typical usage as well as some pointers to existing filtering algorithms.

Keywords: constraint programming, global constraint, catalogue, graph, automaton, first order formula, meta-data, ontology, symmetry, counting.

December 14, 2014

Preface

1 Getting started

2 Describing Global Constraints
   2.1 Global constraint: what it is, and what it is not
   2.1.1 Checker view
   2.1.2 Feasibility view
   2.1.3 Filtering view
   2.1.4 Explanation view
   2.1.5 Cost violation view
   2.1.6 Reification view
   2.1.7 Counting view
   2.2 Describing the arguments of a global constraint
   2.2.1 Basic data types
   2.2.2 Compound data types
   2.2.3 Restrictions
   2.2.4 Declaring a global constraint
   2.2.5 Describing symmetries between arguments
   2.2.6 Describing global constraints in terms of graph properties
   2.3 Semantic links between global constraints
   2.3.1 Assignment dimension added
   2.3.2 Assignment dimension removed
   2.3.3 Attached to cost variant
   2.3.4 Common keyword
   2.3.5 Comparison swapped

Preface

“Although dictionaries give the impression of analyzing words all the way down to their very atoms, all they do in fact is graze their surfaces.”
– Douglas Hofstadter, Emmanuel Sander, *Surfaces and Essences*

This catalogue presents a list of global constraints. Within this catalogue the term *global constraint* should be understood as an *expressive and concise condition involving a non-fixed number of variables*. This informal definition does not make any assumption neither about the potential use of a global constraint nor about the techniques\(^1\) associated with the development of global constraints. It contains about 431 constraints, which are explicitly described in terms of graph properties and/or automata and/or first order logic formulae and/or conjunction of other constraints.

This *Global Constraint Catalogue* is an expanded version of the list of global constraints presented in [28] and an updated version of [43]. The principle used for describing global constraints has been slightly modified in order to deal with a larger number of global constraints. Since 2003, we try to provide an automaton that recognises the solutions associated with a global constraint. Since 2009, we also try to provide a first order logic formula for defining the solutions accepted by a geometrical constraint.

Writing a dictionary is a long process, especially in a field where new words are defined every year. In this context, one difficulty is to express explicitly the meaning of global constraints in terms of meta-data. Finding an appropriate and concise description that both easily captures the meaning of most global constraints and allows fast inferences\(^2\) involving global constraints seems to be a tricky task.

One may wonder how so many constraints can be used at all in practice? However many fields produce a number of articles containing partial and specific results. Within the area of global constraints, we fill that trying extracting and classifying such knowledge, as well as providing meta-data for encoding it, may be a help, both for humans and machines, to exploit systematically ongoing research results and to put these results in perspective. Work about the *constraint seeker* [61] and the *model seeker* [62] relies on these meta-data to identify global constraints and to automatically come up with a constraint model from a set of positive samples.

\(^1\) As quoted by J. N. Hooker in [225], “identifying a field with its techniques is an intellectually as well as practically unsatisfying” and has a lot of drawbacks.

\(^2\) E.g., in the context of the constraint and model seeker [61, 62] we have gradually identified a number of properties for inferring that a constraint/conjunction of constraints is implied by another constraint/conjunction of constraints.
Goal of the catalogue. This catalogue has four main goals. First, it provides an overview of most of the different global constraints that were gradually introduced in the area of constraint programming since the work of J.-L. Laurière on ALICE [267]. It also identifies new global constraints for which no existing published work exists. The global constraints are arranged in alphabetic order, and for all of them a description and an example are systematically provided. When available, it also presents some typical usage as well as some pointers to existing filtering algorithms.

Second, the global constraints described in this catalogue are not only accessible to humans, who can read the catalogue for searching for some information. It is also available to machines, which can read and interpret it. This is why there exists an electronic version of this catalogue where one can get, for most global constraints, a complete description in terms of meta-data. In fact, most of this catalogue and its figures were automatically generated from this electronic version by a computer program. This description is based on three complementary ways to look at a global constraint. The first one defines a global constraint as searching for a graph with specific properties [27], the second one characterises a global constraint in terms of an automaton that only recognises the solutions associated with that global constraint [39, 317], while the third one defines in the context of geometric constraints a global constraint as a restricted first order logic formula [107]. The key point of these descriptions is their ability to define explicitly in a concise way the meaning of most global constraints. In addition these descriptions can also be systematically turned into polynomial filtering algorithms.

Third, we hope that this unified description of apparently diverse global constraints will allow for establishing a systematic link between the properties of basic concepts used for describing global constraints and the properties of the global constraints as a whole.

Finally, we also hope that it will attract more people from the algorithmic community into the area of constraints. To a certain extent this has already started in places like CWI in Amsterdam, the Max-Planck für Informatik (Saarbrücken) or the university of Waterloo. We also hope that it will attract people from combinatorics in order to produce theories and knowledge that could nicely unify and/or put in perspective different aspects of constraints (i.e., breaking symmetries, counting the number of solutions). Identifying bijections [408, 407] relating global constraints to well known combinatorial objects would be a step in this direction.

Use of the catalogue. The catalogue is organised into five chapters:

- Chapter 1 provides a short overview of the main entries you may first consult when you are not familiar with the catalogue.

---

3 Automata were first used in the 90ies by N. R. Vempaty [442] and J. Amilhastre [8] in the context of constraint networks. Later on in 2007, they were also used by M.-C. Coté et al. [134] in the context of linear programming.

4 This is currently the case only for a few constraints like ALLDIFFERENT, CYCLE or TREE. The information about the number of solutions to a global constraint in the Counting slot could certainly help identifying relevant combinatorial objects.
• Chapter 2 explains how the meaning of global constraints is described in terms of graph-properties or in terms of automata. On the one hand, if one wants to consult the catalogue for getting the informal definition of a global constraint, examples of use of that constraint or pointers to filtering algorithms, then one only needs to read the first section of Chapter 2: describing the arguments of a global constraint, page 14. On the other hand, if one wants to understand those entries describing explicitly the meaning of a constraint then all the material of Chapter 2 is required.

• Chapter 3 describes the content of the catalogue as well as different ways for searching through the catalogue. This material is essential.

• Chapter 4 covers additional topics, such as the differences from the 2000 report [28] on global constraints, the generation of implied constraints that are systematically linked to the graph-based description of a global constraint, and the electronic version of the catalogue. The material describing the format of the entries of a global constraint is mandatory for those who want to exploit the electronic version in order to write pre-processors for performing various tasks for a global constraint.

• Finally, Chapter 5 corresponds to the catalogue itself, which gives the global constraints in alphabetical order.

Acknowledgments. Nicolas Beldiceanu was the principal investigator and main architect of the constraint catalogue, provided the main ideas, and wrote a checker for the constraint descriptions, a figure generation program for the constraint descriptions and an evaluator for most constraints. Jean-Xavier Rampon provided the proofs for the graph invariants. Mats Carlsson contributed to the design of the meta-data format, generated some of the automata together with their negated forms, provide some constraints evaluators, and wrote the program that created the \LaTeX version of this catalogue from the constraint descriptions.

The idea of describing explicitly the meaning of global constraints in a declarative way has been inspired by the work on meta-knowledge of Jacques Pitrat [327, 328, 329].

We are grateful to Magnus Ågren, Abderrahmane Aggoun, Ernst Althaus, María Andreina Francisco Rodríguez, Gregor Baues, Christian Bessière, Mohammed Haykel Boukadida, Éric Bourreau, Sebastian Brand, Pascal Brisset, Hadrien Cambazard, Gilles Chabert, Peter Chan, Philippe Charlier, François Clautiaux, Evelyne Contejean, Radoslaw Cymer, Romuald Debruyne, Frédéric Deces, Sophie Demassey, Alban Derrien, Mehmet Dincbas, Grégoire Doms, François Fages, Jean-Guillaume Fages, Pierre Flener, Xavier Gandibleux, Yan Georget, Dávid Hanák, Emmanuel Hebrard, Pascal Van Hentenryck, Fabien Hermenier, Han J. A. Hoogeveen, Stefan Hougardy, Giuseppe F. Italiano, Antoine Jouglet, Narendra Jussien, Irit Katriel, Waldemar Kocjan, Per Kreuger, Krzysztof Kuchcinski, Mikael Zayenz Lagerkvist, Michel Leconte, Christophe Lecoutre, Arnaud Letort, Xavier Lorca, Michael J. Maher, Michael Marte, Julien Martin, Julien Menana, Dominique Michelucci, Per Mild-
We are grateful to Irit Katriel who contributed by updating the description of some filtering algorithms related to flow and matching of the catalogue, to Luis Quesada and Stéphane Zampelli who provide inputs for the \texttt{DOM\_REACHABILITY}, \texttt{SUBGRAPH\_ISOMORPHISM} and \texttt{GRAPH\_ISOMORPHISM} constraints, and to Radoslaw Szymanek and Guido Tack for providing the correspondence of global constraints of the catalogue with the constraints of \texttt{JaCoP} and \texttt{Gecode}. We are also especially grateful to Sophie Demassey both, for creating the on-line version of the catalogue (\url{http://sofdem.github.io/gccat/}) and for writing down the entry related to the \texttt{cumulative longest hole problems}, to Helmut Simonis both, for designing the XML schema (see Section \ref{ch:xml}) for the global constraints and their arguments, for providing the corresponding generation programs, for providing data for several rectangle placement problems, and for providing the code for generating the figures that display the number of solutions to a constraint wrt some of their parameters, and to Pierre Flener and Justin Pearson for providing feedback with respect to the \texttt{Symmetry} slot of global constraints. Moreover Eliane Vacheret helps for structuring many exercises of the \texttt{Quiz} slot of the core constraints and did a first version of the \texttt{online version constraint course}, and Pierre Flener provides additional feedback on the exercises on the core constraints.

The geometric constraints \texttt{GEOST} and \texttt{VISIBLE} as well as the constraints related to the \texttt{Region Connection Calculus} where integrated within the catalogue while working on the European Union Sixth Framework Programme Contract FP6-034691 “NetWMS”.

The glue matrices of the automata were first worked out by María Andreina Francisco Rodríguez and Nicolas Beldiceanu, and latter on systematically tested with a program by Mats Carlsson.

Finally, we want to acknowledge the continuing support of SICS and EMN for providing excellent working conditions over the years. The part of this work related to graph properties in Chapter \ref{ch:graph} was done while the corresponding author was working at SICS.

Readers may send their suggestions via email to the corresponding author with \texttt{catalogue} as subject.

1

Getting started

If you are using the pdf version of the catalogue use Adobe Reader if you want to be sure to see PDF annotations.\footnote{Since we are using the \LaTeX{} package \texttt{pdfcomment} and since most PDF viewers do not support PDF annotations.} If you do not see on your screen a small yellow bullet at the beginning of this paragraph, you are using a PDF viewer that does not fully support PDF annotations. Within keywords and constraints, the icons

\begin{itemize}
\item[\footnotesize{\begin{tikzpicture}
\fill[fill=yellow!25] (-0.1,0) -- (0,0) arc (180:0:0.3cm) -- (0.1,0);
\fill[fill=white] (-0.1,0) -- (0,0) arc (180:0:0.3cm) -- (0.1,0);
\end{tikzpicture}}]
\text{indicates a point of interest (e.g., a necessary condition, a typical use),}
\end{itemize}

\begin{itemize}
\item[\footnotesize{\begin{tikzpicture}
\fill[fill=red!25] (-0.1,0) -- (0,0) arc (180:0:0.3cm) -- (0.1,0);
\fill[fill=white] (-0.1,0) -- (0,0) arc (180:0:0.3cm) -- (0.1,0);
\end{tikzpicture}}]
\text{denotes a typical error or a common misunderstanding.}
\end{itemize}

The main entries you may consult if you want to have a first look to the catalogue are:

- To get an idea of the multiple facets of global constraints look at Section 2.1.
- To get an idea of how global constraint arguments are described look at Section 2.2.
- To search in the catalogue look at Section 3.3.
- To search a constraint from a keyword look at Section 3.7.
- To get an idea how keywords are structured look at Section 3.6.
- To know available semantic links between constraints look at Section 2.6.
- To get through the core global constraints look at the keyword core. Most core global constraints have a small set of exercises with solutions for checking that different facets of a core constraint are well understood. These exercises are located in the Quiz slot at the end of a constraint catalog entry, e.g. for \texttt{ALLDIFFERENT} see page 557.
- To see how constraints symmetries are described look at Section 2.2.5.
1. GETTING STARTED

- To get an idea of **general filtering techniques** look at the meta-keyword **filtering** and more specifically to the entries **Berge-acyclic constraint network, constructive disjunction, flow and sweep**. To get the notion of **consistency** achieved by a filtering algorithm look at the keywords **arc-consistency** and **bound-consistency**.

- To get an idea of **modelling techniques** and of **modelling exercises** look at the meta-keywords **modelling** and **modelling exercises**.

- To get an idea of **reformulations** of global constraints look at Section 2.5.

- To get an idea of general ways to **explicitly represent the meaning of global constraints** look at (a) Section 2.3 for the **graph property based description**, (b) Section 2.4 for the **automaton based description**, (c) the reference [107]) for the **logical based description** (e.g., see the **Logic** slot of **MEET_SBOXES**).

- To get an idea of the **meta-data** used for describing various aspects of a constraint look at Section 4.5.1 for the **facts** and Section 4.5.2 for the **XML schema**.

- To get the **correspondence of global constraints** of the catalogue with concrete constraint systems or modelling languages, such as **Choco, Gecode, JaCoP, MiniZinc**, or **SICStus** look at Appendix C.

Some material of the global constraint catalogue may be used for teaching global constraints, namely:

- Section 2.1 to get a first idea about global constraints,

- The definition and use of the **core global constraints** starting with **ALLDIFFERENT** and **ELEMENT**, continuing with **CUMULATIVE, DIFFN** and **CYCLE**, and finishing with **GLOBAL_CARDINALITY, NVALUE**, and **SORT**. Exercises for these constraints are located in the **Quiz** slot at the end of a constraint catalog entry. Exercises involving more than one constraint are available from the keyword **Modelling exercises**. All exercises are listed at the end of the catalogue page 3930.

Moreover additional on-line material that could also be used for teaching is:

- An **online version constraint course** focussing on core global constraints is available where exercises can be done interactively.

- The **constraint seeker** allows users searching for global constraints, given positive and negative, fully instantiated examples without knowing neither the names of the constraints nor the way they arguments are organised (see the **on-line help** for using that tool).

We first introduce the notion of global constraint as well as the different facets attached to global constraints. We then motivate the need for an explicit description of global constraints and then present the graph-based as well as the automaton-based descriptions used throughout the catalogue. On the one hand, the graph-based representation considers a global constraint as a subgraph of an initial given graph. This subgraph has to satisfy a set of required graph properties. On the other hand, the automaton-based representation denotes a global constraint as a hypergraph constructed from a given constraint checker. A constraint checker is a program that takes an instance of a constraint for which all variables are fixed and tests whether the constraint is satisfied or not.
regular structure, which should give the opportunity for efficient filtering algorithms taking advantage of this structure.

We now present our motivations for an explicit description of the meaning of global constraints. The current trend\(^2\) is to first use natural language for describing the meaning of a global constraint and second to work out a specialised filtering algorithm. Since we have a huge number of potential global constraints that can be combined in a lot of ways, this is an immense task. Since we are also interested in providing other services, such as visualisation [463, 397, 400], explanations [371], cuts for linear programming [227], moves for local search [88], generation of clauses for SAT solvers [306], generation of multivalued decision diagrams that represent compact relaxations of global constraints [224], soft global constraints [325, 57, 435], learning implied global constraints [66], simplifying away fixed variables from global constraints when they have the same effect on the remaining unfixed variables in order to automatically identify equivalent subproblems during search [124], and specialised heuristics for each global constraint this is even worse. One could argue that a candidate for describing explicitly the meaning of global constraints would be second order predicate calculus. This could perhaps solve our description problem but would, at least currently, not be useful for deriving any filtering algorithm.\(^3\) For a similar reason Prolog was restricted to Horn clauses for which one had a reasonable solving mechanism. What we want to stress through this example is the fact that a declarative description is really useful only if it also provides some hints about how to deal with that description. Our first choice of a graph-based representation has been influenced by the following observations:

- The concept of graph has its roots in the area of mathematical recreations (see, for example, L. Euler [164], H. E. Dudeney [155], E. Lucas [280] and T. P. Kirkman [249]), which was somehow the ancestor of combinatorial problems. In this perspective a graph-based description makes sense.

- In one of the first books introducing graph theory [63], C. Berge presents graph theory as a way of grouping apparently diverse problems and results. This was also the case for global constraints.

- The parameters associated with graphs are concrete and concise. Moreover a lot of results about graphs can be expressed in terms of graph invariants involving various graph parameters that are valid for specific graph classes. In essence, formulae are a kind of declarative statement that is much more compact than algorithms.

- Finally, it is well known that graph theory is an important tool [291] with respect to the development of efficient filtering algorithms [351, 353, 356, 364, 292, 244, 54, 433, 344].

Our second choice of an automaton-based representation has been motivated by the following observation. Writing a constraint checker is usually a straightforward

\(^2\)This can be noted in all constraint manuals where the description of the meaning is always informal.

\(^3\)One could perhaps use a system like MONA [221] or some ideas from [91] for getting a constraint checker in the context of the graph-based representation.
task. The corresponding program can usually be turned into an automaton. Of course an automaton is typically used on a fixed sequence of symbols. But, in the context of filtering algorithms, we have to deal with a sequence of variables. For this purpose we have shown [39] for some automata how to decompose them into a conjunction of smaller constraints. In this context, a global constraint can be seen as a hypergraph corresponding to its decomposition. The hypergraph has two types of hyperedges: the first type corresponds to transition constraints describing the behavior of the automaton, while the second type represents signature constraints encoding the mapping of arguments of the constraint to symbols of the alphabet of the automaton.

2.1 Global constraint: what it is, and what it is not

As said in the preface, the term global constraint should be understood as an expressive and concise condition involving a non-fixed number of partially known objects. The ideas conveyed by this informal definition are:

- **Context independence** points to the fact that the condition may be typically useful in more than one context. Like a word in the context of natural language, a global constraint encapsulates its own concept that is independent from any specific use. Like words, once you have the right concepts, you can directly reason at the appropriate level of abstraction.

- **Conciseness** means that the condition should be expressible in a compact way, typically by one or two sentences in natural language. The condition directly mentions objects that match the right level of abstraction it considers, i.e., when appropriate it does not just refer to a flat list of variables. If necessary, the condition typically involves one or several collections of objects (e.g. tasks), where each object has a number of attributes (e.g., an origin, a duration and an end if we consider tasks). An attribute may correspond either to a constant (i.e., a fixed value), or to a variable.

The second key point conveyed by this informal definition is that, it does not make any assumption about the techniques associated with the potential use of global constraints. Consequently, a global constraint cannot just be reduced to:

1. A concept that is only linked to constraint programming.
2. A function that computes a result from a given set of input arguments.
3. An algorithm that, given a condition on a set of variables, removes some values to enforce that condition.
4. A way to express a condition as a set of clauses or as a set of linear constraints.

---

4In Sections 2.3 and 2.4 we will describe some possible ways of defining concisely the meaning of a significant number of global constraints in a formal way.
2.1. GLOBAL CONSTRAINT: WHAT IT IS, AND WHAT IT IS NOT

We now illustrate through the example of the ALLDIFFERENT constraint different facets of a global constraint. Given a collection of variables \(\langle x_1, x_2, \ldots, x_n \rangle\), the \textsc{AllDifferent}(\(\langle x_1, x_2, \ldots, x_n \rangle\)) constraint forces all variables \(x_1, x_2, \ldots, x_n\) to be assigned distinct values. We successively consider the checker view, the feasibility view, the filtering view, the explanation view, the cost violation view, the reification view, the counting view and the property view.

2.1.1 Checker view

Considering a constraint for which all variables are fixed, the checker view is about finding an algorithm that checks whether a ground instance of that constraint holds or not. In the context of learning models, the usage of dedicated checkers rather than general filtering algorithms is crucial for performance issues.

For the \textsc{AllDifferent}(\(\langle x_1, x_2, \ldots, x_n \rangle\)) constraint one can first sort the sequence \(x_1, x_2, \ldots, x_n\) and then check that adjacent values are distinct, or alternatively, insert each value into a hash table in order to check that no value occurs more than once.

2.1.2 Feasibility view

Given a constraint where not all variables are fixed yet, a question is whether that constraint has at least one solution or not. We assume that all the not yet fixed variables must be assigned a value in a finite set of values. In this context we are looking for a necessary, and possibly sufficient, condition that can be evaluated in polynomial time with respect to the size of the arguments of that constraint.

For the \textsc{AllDifferent}(\(\langle x_1, x_2, \ldots, x_n \rangle\)) constraint we associate a variable-value graph where (1) each vertex corresponds to its variables and to the values that can be assigned to these variables, and (2) each edge corresponds to the fact that a variable can be assigned a given value. A necessary and sufficient condition is that the cardinality of the maximum matching, i.e. the maximum number of edges such that no two edges have a vertex in common, in this variable-value graph is equal to the number of variables.

2.1.3 Filtering view

Once we know that a constraint for which not all variables are fixed yet is potentially feasible, the next question is to identify variable-value pairs of the form \((\text{var}, \text{val})\) such that, if value \text{val} is assigned to variable \text{var}, the constraint has no solution. Since removing such values reduces a priori the search space, filtering is strongly supported by the implicit motto of constraint programming that \textit{the more you prune the better}. Assuming that you already have a necessary and sufficient condition that can be evaluated in polynomial time for checking whether a constraint has at least one solution or not, you can directly reuse it for checking whether a value can be assigned or not to a variable. Since the number of variable-value pairs to check may be quadratic with respect to the total number of variables and values one usually prefers developing a dedicated filtering algorithm that is less costly than checking the feasibility condition on each variable-value pair.
2. DESCRIBING GLOBAL CONSTRAINTS

For the ALLDIFFERENT constraint a first filtering algorithm [351] is based on a characterisation of the edges of the variable-value graph that belong to a maximum matching but not to all. A matching on a graph is a set of edges of the graph such that no two edges have a vertex in common; it is maximum if its number of edges is maximum. We first introduce a digraph $\overrightarrow{G}_M$ that is associated with a matching $M$ that matches all variables of the ALLDIFFERENT constraint. The vertices of $\overrightarrow{G}_M$ are defined as the variables and the values that can be assigned to the variables of the ALLDIFFERENT constraint. To each value $\text{val}$ that can be assigned to a variable $\text{var}$ corresponds an arc of $\overrightarrow{G}_M$ from $\text{var}$ to $\text{val}$. Finally, if value $\text{val}$ is matched to variable $\text{var}$ in the matching $M$ we add the reverse arc from $\text{val}$ to $\text{var}$ to the arcs of $\overrightarrow{G}_M$.

Now a variable $\text{var}$ in the matching $M$ corresponds an arc of $\overrightarrow{G}_M$ defined as the variables and the values that can be assigned to the variables of the ALLDIFFERENT constraint. The vertices of $\overrightarrow{G}_M$ are defined by $\text{var} \in \overrightarrow{G}_M$ and its five strongly connected components s.c.c. $k$ ($1 \leq k \leq 5$): 8 can be assigned to $V_7$ (blue arc) since the path $(V_7, 8, 9)$ ends up in an unmatched value, but 3 cannot be assigned to $V_2$ (red arc) since 3 and $V_2$ do not belong to the same strongly connected component and since there is no path from $V_2$ to the unique unmatched value 9.

Another filtering algorithm for ALLDIFFERENT based on Hall intervals just focuses on adjusting the minimum and maximum values of the variables. Given a set of domain variables, a Hall interval is an interval of values [low, up] denoted by $\mathcal{H}_{[\text{low, up}]}$ such that there are $\text{up} - \text{low} + 1$ variables whose domains are contained in $\mathcal{H}_{[\text{low, up}]}$. A minimal Hall interval $\mathcal{H}_{[\text{low}', \text{up}']}$ is a Hall interval that does not contain any Hall interval $\mathcal{H}_{[\text{low}, \text{up}]}$ such that either $\text{low} = \text{low}'$ or $\text{up} = \text{up}'$. Given a Hall interval $\mathcal{H}$ and a variable $V$ whose domain is not included in $\mathcal{H}$ but intersects $\mathcal{H}$, the idea is to adjust the minimum (respectively maximum) value of variable $V$ to the smallest (respectively largest) value that does not belong to $\mathcal{H}$. Figure 2.2 illustrates this idea on the constraint ALLDIFFERENT($(V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8)\text{ with } V_1 \in [1, 2], V_2 \in [1, 3], V_3 \in [3, 4], V_4 \in [3, 5], V_5 \in [4, 5], V_6 \in [6, 7], V_7 \in [6, 8], V_8 \in [8, 9]$) with $V_1 \in [1, 2], V_2 \in [1, 3], V_3 \in [2, 5], V_4 \in [4, 5], V_5 \in [5, 6], V_6 \in [4, 6], V_7 \in [1, 9], V_8 \in [8, 9]$.

- Part (A) of Figure 2.2 shows in light blue, in light pink and in light yellow
the three minimal Hall intervals associated with the initial domains of variables $V_1, V_2, \ldots, V_9$.

- $H_{[1,2]}$ corresponds to interval $[1, 2]$, which contains the domains of $V_1$ and $V_2$.
- $H_{[4,6]}$ corresponds to interval $[4, 6]$, which contains the domains of $V_4, V_5$ and $V_6$.
- $H_{[8,9]}$ corresponds to interval $[8, 9]$, which contains the domains of $V_8$ and $V_9$.

• Part (B) of Figure 2.2 shows the first propagation step with respect to the Hall intervals $H_{[1,2]}, H_{[4,6]}$ and $H_{[8,9]}$. First note that variables $V_3$ and $V_7$ are the only variables whose domain is not included in a Hall interval. Consequently $V_3$ and $V_7$ are candidates for adjusting their minimum or maximum domain values.

  - Since the minimum value of $V_3$, that is i.e. value $2$, belongs to the Hall interval $H_{[1,2]}$ we adjust the minimum of $V_3$ to the smallest value that does not yet belong to any Hall interval, i.e. value $3$.
  - Since the maximum value of $V_3$, that is i.e. value $5$, belongs to the Hall interval $H_{[4,6]}$ we adjust the maximum value of $V_3$ to the largest value that does not yet belong to any Hall interval, i.e. value $3$.
  - Since the minimum value of $V_7$, that is i.e. value $1$, belongs to the Hall interval $H_{[1,2]}$ we adjust the minimum of $V_7$ to the smallest value that does not yet belong to any Hall interval, i.e. value $3$.
  - Since the maximum value of $V_7$, that is i.e. value $9$, belongs to the Hall interval $H_{[8,9]}$ we adjust the maximum of $V_7$ to the largest value that does not yet belong to any Hall interval, that is i.e. value $7$.

• Part (C) of Figure 2.2 shows the second propagation step with respect to the new Hall interval $H_{[3,3]}$. Now $V_7$ is the only variable whose domain is not included in a Hall interval so it is a candidate for adjusting its minimum or maximum domain value.

  - Since the minimum value of $V_7$, i.e. value $3$, belongs to the new Hall interval $H_{[3,3]}$ we adjust the minimum of $V_7$ to the smallest value that does not yet belong to any Hall interval, i.e. value $7$.

• Finally, part (D) of Figure 2.2 shows all the minimal Hall intervals after reaching the fix point of the filtering, where $H_{[7,7]}$ is a new minimal Hall interval.

2.1.4 Explanation view

Given a constraint that cannot be satisfied the goal is to identify a smallest subset of variables and values for explaining that the constraint has no solution. Similarly, given a constraint that can be satisfied and a variable-value pair $(var, val)$ such that, if value $val$ is assigned to variable $var$ the constraint has no solution, the same question arises.
2. DESCRIBING GLOBAL CONSTRAINTS

Figure 2.2: Steps (A), (B), (C) and (D) for filtering the minimum and maximum values wrt Hall intervals \( H_{[\text{low}, \text{up}]} \) for \textsc{alldifferent} \((V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9)\) with \( V_1 \in [1, 2], V_2 \in [1, 2], V_3 \in [2, 5], V_4 \in [4, 5], V_5 \in [5, 6], V_6 \in [4, 6], V_7 \in [1, 9], V_8 \in [8, 9], V_9 \in [8, 9] \). Each horizontal grey strip corresponds to a set of consecutive values that do not belong to the domain of a variable, while each horizontal red strip represents an adjustment of the minimum or the maximum value of the domain of a variable.

Explanations are expressed in term of values that should be added to the domains of some variables in order to prevent unsatisfiability or filtering.

For the \textsc{alldifferent} constraint Figure 2.3 provides the explanation attached to the instance described in Figure 2.1, i.e. what arcs should be added to prevent value 3 from being removed from the domain of variable \( V_2 \).
2.1.5 Cost violation view

Considering a constraint for which all variables are fixed such that the constraint does not hold, a question is to evaluate the degree of violation of that constraint assuming that for a satisfied constraint the degree of violation is equal to zero.

For the \textsc{alldifferent} constraint we can define its degree of violation by the minimum number of variables to reassign in order to get a solution. This is called the \textit{variable-based degree of violation}. We can also define its degree of violation by the number of pairs of variables that do not satisfy the disequality constraint. This is called the \textit{decomposition-based degree of violation}. Figure 2.4 illustrates these two degree of violation costs.

2.1.6 Reification view

Suppose we want to associate a 0-1 domain variable \( b \) to a constraint \( C \) and maintain the equivalence \( b \equiv C \). This is called the reification of \( C \). For most global constraints this can be achieved by reformulating the global constraint as a conjunction of pure functional dependency constraints together with constraints that can be easily reified, e.g. linear constraints involving at most two variables [37].

We can reify the \textsc{alldifferent}(\( \langle x_1, x_2, \ldots, x_n \rangle \)) constraint by using the idea of sorting its variables (i.e., the pure functional dependency part) and by stating that within the sorted list of variables adjacent variables are in strictly increasing order. This
2. DESCRIBING GLOBAL CONSTRAINTS

Variable-based degree of violation:

\[ \text{ALLDIFFERENT}(\{2, 5, 2, 2, 5\}) \]

\[
\text{violation} = (\#5 - 1) + (\#2 - 1) = (2 - 1) + (3 - 1) = 3
\]

(three values need to be changed)

Figure 2.4: Illustration of the variable-based and the decomposition-based degrees of violation for \text{ALLDIFFERENT}(\{2, 5, 2, 2, 5\}), where \#v denotes the number of occurrences of value v in the argument of the \text{ALLDIFFERENT} constraint instance

leads to the following expression \( \text{SORT}(\langle x_1, x_2, \ldots, x_n \rangle, \langle y_1, y_2, \ldots, y_n \rangle) \land (y_1 < y_2 \land y_2 < y_3 \land \cdots \land y_{n-1} < y_n) \equiv b. \)

2.1.7 Counting view

Considering a constraint for which not all variables are fixed yet, a question is to count, or estimate, its number of solutions. This is useful for writing heuristics that take into account the tightness of the constraints in order, for example, to select the next variable to assign. Considering a pure functional dependency constraint it is interesting to consider how the number of solutions to that constraint varies depending on the value of the pure functional dependency parameter (e.g., in the context of the \text{NVALUE}(N, VARIABLES) constraint, its number of solutions if extremely low when \( N = 1 \), then increase as \( N \) increases up to a point where it decreases again and ends up with \( N = |\text{VARIABLES}| \) like an \text{ALLDIFFERENT}). This is useful, for example, for ranking pure functional dependency constraints in the context of the constraint seeker [61].

Counting the number of solutions to an \text{ALLDIFFERENT} constraint is equivalent to counting the number of maximum matchings in a bipartite graph, which is \#P-complete [424]. Consequently faster approximations for estimating the number of solutions are used in practice [459].

2.1.8 Property view

If we want to reason about constraints we need to know their properties. Examples of properties of a constraint with respect to one of its arguments are:

- A constraint \( c(\langle x_1, x_2, \ldots, x_n \rangle) \) is \text{contractible} if each ground satisfied instance \( c(\langle \text{val}_1, \text{val}_2, \ldots, \text{val}_n \rangle) \) is still satisfied if we remove any of its \( \text{val}_i \) (\( 1 \leq i \leq n \)).

- A constraint \( c(\langle x_1, x_2, \ldots, x_n \rangle) \) is \text{extensible} if each ground satisfied instance \( c(\langle \text{val}_1, \text{val}_2, \ldots, \text{val}_n \rangle) \) is still satisfied if we insert any value into the sequence \( \text{val}_1, \text{val}_2, \ldots, \text{val}_n \).
Examples of properties of a constraint with respect to another constraint are:

- The fact that a constraint implies another constraint under the assumption that both constraints have exactly the same arguments.

- The fact that if a constraint holds then another constraint does not hold, under the assumption that both constraints have exactly the same arguments.

Implications between two different constraints are provided by the See also slot (i.e., see implies, implied by and negation) as well as by the Conditional implication slot.

Regarding the ALLDIFFERENT constraint we have:

- It is contractible since removing a value from a ground satisfied instance leaves the remaining constraint satisfied.

- It is not extensible since adding a value into a ground satisfied instance may not necessarily lead to a satisfied constraint.

- The ALLDIFFERENT constraint is implied by more specific constraints, such as the ALLDIFFERENT_CONSECUTIVE_VALUES constraint, which in addition forces all used values to be consecutive.

We now illustrate how to use such knowledge as a method for trying to check that a given conjunction of identical constraints, i.e. constraints with the same name, is implied by another conjunction of also identical constraints. This subproblem originates from learning models where we want to keep only the more general conjunctions of identical constraints. Consider the conjunction $C_1$

$$
\begin{align*}
\{ & \text{ALLDIFFERENT}((v_1, v_2, v_3, v_4)) \land \\
& \text{ALLDIFFERENT}((v_5, v_6, v_7, v_8)) \}
\end{align*}
$$

where ALLDIFFERENT_CONSECUTIVE_VALUES forces variables to take consecutive distinct values, and the conjunction $C_2$

$$
\begin{align*}
\{ & \text{ALLDIFFERENT}((v_1, v_2)) \land \text{ALLDIFFERENT}((v_3, v_4)) \land \\
& \text{ALLDIFFERENT}((v_5, v_6)) \land \text{ALLDIFFERENT}((v_7, v_8)) \}
\end{align*}
$$

Conjunction $C_1$ implies conjunction $C_2$ since every constraint of $C_2$ is implied by at least one constraint of $C_1$. For example, ALLDIFFERENT($\{v_1, v_2\}$) is implied by ALLDIFFERENT_CONSECUTIVE_VALUES($\{v_1, v_2, v_3, v_4\}$) since:

- ALLDIFFERENT_CONSECUTIVE_VALUES($\{v_1, v_2, v_3, v_4\}$) \implies ALLDIFFERENT($\{v_1, v_2, v_3, v_4\}$).

- ALLDIFFERENT($\{v_1, v_2, v_3, v_4\}$) is contractible, it implies ALLDIFFERENT($\{v_1, v_2\}$).
2.2 Describing the arguments of a global constraint

Since global constraints have to receive their arguments in some form, no matter whether we use the graph-based or the automaton-based description, we start by describing the abstract data types that we use in order to specify the arguments of a global constraint. These abstract data types are not related to any specific programming language like Caml, C, C++, Java, or Prolog. If one wants to focus on a specific language, then one has to map these abstract data types to the data types that are available within the considered programming language. In a second phase we describe all the restrictions that one can impose on the arguments of a global constraint. Finally, in a third phase we show how to use these ingredients in order to declare the arguments of a global constraint.

2.2.1 Basic data types

We provide the following basic data types:

- **atom** corresponds to an atom. Predefined atoms are MININT and MAXINT, which respectively correspond to the smallest and to the largest integer.

- **int** corresponds to an integer value.

- **dvar** corresponds to a domain variable. A domain variable $V$ is a variable that will be assigned an integer value taken from an initial finite set of integer values denoted by $\text{dom}(V)$. $\underline{V}$ and $\overline{V}$ respectively denote the minimum and the maximum values of $\text{dom}(V)$.

- **fdvar** corresponds to a possibly unbounded domain variable. A possibly unbounded domain variable is a variable that will be assigned an integer value from an initial finite set of integer values denoted by $\text{dom}(V)$ or from interval minus infinity, plus infinity. This type is required for declaring the domain of a variable. It is also required by some systems in the context of specific constraints like arithmetic or ELEMENT constraints.

- **sint** corresponds to a finite set of integer values.

- **svar** corresponds to a set variable. A set variable $V$ is a variable that will be assigned to a finite set of integer values. Its lower bound $\underline{V}$ denotes the set of integer values that for sure belong to $V$, while its upper bound $\overline{V}$ denotes the set of integer values that may belong to $V$. $\text{dom}(V) = \{v_1, \ldots, v_n, v_{n+1}, \ldots, v_m\}$ is a shortcut for combining the lower and upper bounds of $V$ in a single notation:
  - Bold values designate those values that only belong to $V$.
  - Plain values indicate those values that belong to $\overline{V}$ and not to $\underline{V}$.

- **mint** corresponds to a multiset of integer values.

- **mvar** corresponds to a multiset variable. A multiset variable is a variable that will be assigned to a multiset of integer values.
• **real** corresponds to a **real number**.

• **rvar** corresponds to a **real variable**. A real variable is a variable that will be assigned a real number taken from an initial finite set of intervals. A real number is usually represented by an interval of two floating point numbers.

Beside domain, set, multiset and float variables we have not yet introduced **graph variables** [151]. A graph variable is currently simulated by using one set variable for each vertex of the graph (see the third example of type declaration of 2.2.2).
2. DESCRIBING GLOBAL CONSTRAINTS

2.2.2 Compound data types

We provide the following compound data types:

- **list(T)** corresponds to a list of elements of type T, where T is a basic or a compound data type.

- **collection(A_1, A_2, ..., A_n)** corresponds to a collection of ordered items, where each item consists of n > 0 attributes A_1, A_2, ..., A_n. Each attribute is an expression of the form a - T, where a is the name of the attribute and T the type of the attribute (a basic or a compound data type). All names of the attributes of a given collection should be distinct and different from the keyword key, which corresponds to an implicit attribute. Its value is the position of an item within the collection. The first item of a collection is associated with position 1.

The following notations are used for instantiated arguments:

- A list of elements e_1, e_2, ..., e_n is denoted [e_1, e_2, ..., e_n].

- A finite set of integers i_1, i_2, ..., i_n is denoted \{i_1, i_2, ..., i_n\}.

- A multiset of integers i_1, i_2, ..., i_n is denoted \{\{i_1, i_2, ..., i_n\}\}.

- A collection of n items, each item having m attributes, is denoted by 
  \langle a_1 - v_{11} ... a_m - v_{1m}, a_1 - v_{21} ... a_m - v_{2m}, ..., a_1 - v_{n1} ... a_m - v_{nm} \rangle.
  Each item is separated from the previous item by a comma. When the items of the collection involve a single attribute a_1, \langle v_{11}, v_{21}, ..., v_{n1} \rangle can possibly be used as a shortcut for \langle a_1 - v_{11}, a_1 - v_{21}, ..., a_1 - v_{n1} \rangle.

- The i^{th} item of a collection c is denoted c[i].

- The value of the attribute a of the i^{th} item of a collection c is denoted c[i].a.
  Note that, within an arithmetic expression, we can use the shortcut c[i] when the collection c involves a single attribute.

- The number of items of a collection c is denoted |c|.

---

5This attribute is not explicitly defined.
2.2. DESCRIBING THE ARGUMENTS OF A GLOBAL CONSTRAINT

EXAMPLE: Let us illustrate with four examples, the types one can create. These examples concern the creation of a collection of variables, a collection of tasks, a graph variable [151] and a collection of orthotopes.a

- In the first example we define VARIABLES so that it corresponds to a collection of variables. VARIABLES is used, for example, in the ALLDIFFERENT constraint. The declaration VARIABLES : collection(var − dvar) defines a collection of items, each of which having one attribute var that is a domain variable.

- In the second example we define TASKS so that it corresponds to a collection of tasks, each task being defined by its origin, its duration, its end and its resource consumption. Such a collection is used, for example, in the CUMULATIVE constraint. The declaration TASKS : collection(origin − dvar, duration − dvar, end − dvar, height − dvar) defines a collection of items, each of which having the four attributes origin, duration, end and height which all are domain variables.

- In the third example we define a graph as a collection of nodes NODES, each node being defined by its index (i.e., identifier) and its successors. Such a collection is used, for example, in the DAG constraint. The declaration NODES : collection(index − int, succ − svar) defines a collection of items, each of which having the two attributes index and succ which respectively are integers and set variables.

- In the last example we define ORTHOTOPES so that it corresponds to a collection of orthotopes. Each orthotope is described by an attribute orth. Unlike the previous examples, the type of this attribute does not correspond any more to a basic data type but rather to a collection of n items, where n is the number of dimensions of the orthotope.b This collection, named ORThOTOPE, defines for a given dimension the origin, the size and the end of the object in this dimension. This leads to the two declarations:

  - ORTHOTOPE : collection(ori − dvar, siz − dvar, end − dvar).
  - ORTHOTOPES : collection(orth − ORThOTOPE).

ORTHOTOPES is used, for example, in the DIFFN constraint.

---

2.2.3 Restrictions

When defining the arguments of a global constraint, it is often the case that one needs to express additional conditions that refine the type declarations of its arguments. For this purpose we provide restrictions that allow for specifying these additional conditions. Each restriction has a name and a set of arguments and is described by the following items:

- A small paragraph first describes the effect of the restriction,

- An example points to a constraint using the restriction,

- Finally, a ground instance, preceded by the symbol ▶, which satisfies the restriction is given. Similarly, a ground instance, preceded by the symbol ▶, which

---

a An orthotope corresponds to the generalisation of a segment, a rectangle and a box to the n-dimensional case.
b 1 for a segment, 2 for a rectangle, 3 for a box, . . . .
2. DESCRIBING GLOBAL CONSTRAINTS

violates the restriction is proposed. In this latter case, a bold font may be used for pointing to the source of the problem.

Currently the list of restrictions is:

- **in_list(Arg, ListAtoms)**
  - Arg is an argument of type atom,
  - ListAtoms is a non-empty list of distinct atoms.

This restriction forces Arg to be one of the atoms specified in the list ListAtoms.

**EXAMPLE:** An example of use of such restriction can be found in the `CHANGE([NCHANGE, VARIABLES, CTR])` constraint: `in_list(CTR, [=, ≠, <, ≥, >, ≤])` forces the last argument CTR of the `CHANGE` constraint to take its value in the list of atoms `[=, ≠, <, ≥, >, ≤]`.

▶ `CHANGE(1, ⟨var − 4, var − 4, var − 4, var − 4, var − 6⟩, ≠)
▶ CHANGE(1, ⟨var − 4, var − 4, var − 4, var − 6⟩, 3)

- **in_list(Arg, Attr, ListIntOrAtom)**
  - Arg is an argument of type collection,
  - Attr is an attribute of type int or of type atom of the collection denoted by Arg.
  - When Attr is an attribute of type int, ListIntOrAtom is a non-empty list of distinct integers; otherwise, when Attr is an attribute of type atom, ListIntOrAtom is a non-empty list of distinct atoms.

This restriction forces for all items of the collection Arg, the attribute Attr to take its value within the list ListIntOrAtom.

- **in_attr(Arg1, Attr1, Arg2, Attr2)**
  - Arg1 is an argument of type collection,
  - Attr1 is an attribute of type dvar or of type int of the collection denoted by Arg1.
  - Arg2 is an argument of type collection,
  - Attr2 is an attribute of type int of the collection denoted by Arg2.

Let $S_2$ denotes the set of values assigned to the Attr2 attributes of the items of the collection Arg2. This restriction forces the following condition: for all items of the collection Arg1, the attribute Attr1 takes its value in the set $S_2$. 
2.2. DESCRIBING THE ARGUMENTS OF A GLOBAL CONSTRAINT

Example: An example of use of such restriction can be found in the CUMULATIVES (TASKS, MACHINES, CTR) constraint: in_attr(TASKS, machine, MACHINES, id) forces that the machine attribute of each task of the TASKS collection correspond to a machine identifier (i.e., an id attribute of the MACHINES collection).

\[\begin{align*}
& \text{CUMULATIVES}(\langle \text{machine} - 1 \text{ origin} - 2 \text{ duration} - 2 \text{ end} - 4 \text{ height} - 2, \\
& \hspace{1em} \text{machine} - 1 \text{ origin} - 2 \text{ duration} - 2 \text{ end} - 4 \text{ height} - 2, \\
& \hspace{1em} \text{machine} - 2 \text{ origin} - 1 \text{ duration} - 4 \text{ end} - 5 \text{ height} - 5, \\
& \hspace{1em} \text{machine} - 1 \text{ origin} - 4 \text{ duration} - 2 \text{ end} - 6 \text{ height} - 1), \\
& \hspace{1em} \langle \text{id} - 1 \text{ capacity} - 9, \text{id} - 2 \text{ capacity} - 8 \rangle, \leq) \\
\end{align*}\]

\[\begin{align*}
& \text{CUMULATIVES}(\langle \text{machine} - 5 \text{ origin} - 2 \text{ duration} - 2 \text{ end} - 4 \text{ height} - 2, \\
& \hspace{1em} \text{machine} - 1 \text{ origin} - 2 \text{ duration} - 2 \text{ end} - 4 \text{ height} - 2, \\
& \hspace{1em} \text{machine} - 2 \text{ origin} - 1 \text{ duration} - 4 \text{ end} - 5 \text{ height} - 5, \\
& \hspace{1em} \text{machine} - 1 \text{ origin} - 4 \text{ duration} - 2 \text{ end} - 6 \text{ height} - 1), \\
& \hspace{1em} \langle \text{id} - 1 \text{ capacity} - 9, \text{id} - 2 \text{ capacity} - 8 \rangle, \leq) \\
\end{align*}\]

- distinct(Arg, Attrs)
  - Arg is an argument of type collection,
  - Attrs is an attribute of type int or dvar, or a list (possibly empty) of distinct attributes of type int or dvar of the collection denoted by Arg.

For all pairs of distinct items of the collection Arg this restriction forces that there be at least one attribute specified by Attrs with two distinct values. When Attrs is the empty list all items of the collection Arg should be distinct.

Example: An example of use of such restriction can be found in the CYCLE (NCYCLE, NODES) constraint: distinct(NODES, index) forces that all index attributes of the NODES collection take distinct values.

\[\begin{align*}
& \text{CYCLE}(2, \langle \text{index} - 1 \text{ succ} - 2, \text{index} - 2 \text{ succ} - 1, \text{index} - 3 \text{ succ} - 3 \rangle) \\
\end{align*}\]

- increasing_seq(Arg, Attrs)
  - Arg is an argument of type collection,
  - Attrs is an attribute of type int or a list of distinct attributes of type int of the collection denoted by Arg.

Let \( n \) and \( m \) respectively denote the number of items of the collection Arg, and the number of attributes of Attrs. For item \( i \) of the collection Arg let \( t_i \) denotes the tuple of values \( \langle v_{i,1}, v_{i,2}, \ldots, v_{i,m} \rangle \) where \( v_{i,j} \) is the value of attribute \( j \) of Attrs of item \( i \) of Arg. The restriction forces a strict lexicographical ordering on the tuples \( t_1, t_2, \ldots, t_n \).
EXAMPLE: An example of use of such restriction can be found in the `ELEMENT_MATRIX(MAX_I, MAX_J, INDEX_I, INDEX_J, MATRIX, VALUE)` constraint: 

\[
\text{increasing_seq(MATRIX, [i, j]) forces that all items of the MATRIX collection be sorted in strictly increasing lexicographic order on the pair } (i, j).
\]

\[
\text{ELEMENT_MATRIX}((2, 1, 2, (i - 1) 1 v - 4, i - 2; 1 v - 1, i - 2 j - 2 v - 1), 7)
\]

\[
\text{ELEMENT_MATRIX}((2, 1, 2, (i - 1) 1 v - 4, i - 1 j - 1 v - 7, i - 2 j - 1 v - 1, i - 2 j - 2 v - 1), 7)
\]

- **non_increasing_size(Arg, Attr)**
  - Arg is an argument of type collection.
  - Attr is an attribute of the collection denoted by Arg. This attribute should be of type collection.

This restriction forces for each pair of consecutive items Arg[i], Arg[i + 1] that the number of items of the collection Arg[i].Attr is greater than or equal to the number of items of the collection Arg[i + 1].Attr.

EXAMPLE: An example of use of such restriction can be found in the `K_USED_BY(SETS)` constraint: non_increasing_size(SETS.set) forces for all consecutive pairs of items SETS[i], SETS[i + 1] that the number of items of the collection SETS[i].set is not greater than or equal to the number of items of the collection SETS[i + 1].set.

\[
\text{K_USED_BY}((\text{set} = (\text{var} - 5, \text{var} - 1, \text{var} - 1), \\
\text{set} = (\text{var} - 5, \text{var} - 1, \text{var} - 1), \\
\text{set} = (\text{var} - 5, \text{var} - 1)))
\]

\[
\text{K_USED_BY}((\text{set} = (\text{var} - 5, \text{var} - 1, \text{var} - 1), \\
\text{set} = (\text{var} - 5, \text{var} - 1), \\
\text{set} = (\text{var} - 5, \text{var} - 1)))
\]

- **required(Arg, Attrs)**
  - Arg is an argument of type collection.
  - Attrs is an attribute or a list of distinct attributes of the collection denoted by Arg.

This restriction forces that all attributes denoted by Attrs be explicitly used within all items of the collection Arg.

EXAMPLE: An example of use of such restriction can be found in the `CUMULATIVE(TASKS, LIMIT)` constraint: required(TASKS,height) forces that all items of the TASKS collection mention the height attribute.

\[
\text{CUMULATIVE}((\text{origin} - \text{2 duration} - \text{2 end} - \text{4 height} - \text{2}, \\
\text{origin} - \text{2 duration} - \text{2 end} - \text{4 height} - \text{2}, \\
\text{origin} - \text{1 duration} - \text{4 end} - \text{5 height} - \text{5}, \\
\text{origin} - \text{4 duration} - \text{2 end} - \text{6 height} - \text{1}, 12))
\]

\[
\text{CUMULATIVE}((\text{origin} - \text{2 duration} - \text{2 end} - \text{4}, \\
\text{origin} - \text{2 duration} - \text{2 end} - \text{4 height} - \text{2}, \\
\text{origin} - \text{1 duration} - \text{4 end} - \text{5 height} - \text{5}, \\
\text{origin} - \text{4 duration} - \text{2 end} - \text{6 height} - \text{1}, 12))
\]
The required restriction is usually systematically used for every attribute of a collection. It is not used when some attributes may be implicitly defined according to other attributes. In this context, we use the require_at_least restriction, which we now introduce.

- **require-at-least(Atleast, Arg, Attrs)**
  
  - Atleast is a positive integer,
  - Arg is an argument of type collection,
  - Attrs is a non-empty list of distinct attributes of the collection denoted by Arg. The length of this list should be strictly greater than Atleast.

This restriction forces that at least Atleast attributes of the list Attrs be explicitly used within all items of the collection Arg.

**EXAMPLE:** An example of use of such restriction can be found in the CUMULATIVE(TASKS, LIMIT) constraint: require-at_least(2, TASKS, [origin, duration, end]) forces that all items of the TASKS collection mention at least two attributes from the list of attributes [origin, duration, end]. In this context, this stems from the equality origin + duration = end. This allows for retrieving the third attribute from the values of the two others.

\[
\langle \text{origin} - 2 \text{ duration} - 2 \text{ height} - 2, \\
\text{origin} - 2 \text{ end} - 4 \text{ height} - 2, \\
\text{duration} - 4 \text{ end} - 5 \text{ height} - 5, \\
\text{origin} - 4 \text{ duration} - 2 \text{ end} - 6 \text{ height} - 1, 12 \rangle
\]

\[
\langle \text{origin} - 2 \text{ height} - 2, \\
\text{origin} - 2 \text{ duration} - 2 \text{ end} - 4 \text{ height} - 2, \\
\text{origin} - 1 \text{ duration} - 4 \text{ end} - 5 \text{ height} - 5, \\
\text{origin} - 4 \text{ duration} - 2 \text{ end} - 6 \text{ height} - 1, 12 \rangle
\]

- **same_size(Arg, Attr)**
  
  - Arg is an argument of type collection,
  - Attr is an attribute of the collection denoted by Arg. This attribute should be of type collection.

This restriction forces that all collections denoted by Attr have the same number of items.
### 2. DESCRIBING GLOBAL CONSTRAINTS

**EXAMPLE:** An example of use of such restriction can be found in the `DIFFN(ORTHOTOPES)` constraint: `same_size(ORTHOTOPES, orth)` forces all the items of the `ORTHOTOPES` collection to be constituted from the same number of items (of type `ORTHOTOPE`). From a practical point of view, this forces the `DIFFN` constraint to take as its argument a set of points, a set of rectangles, . . . , a set of orthotopases.

```plaintext
▷DIFFN((orth − ⟨ori − 2 siz − 2 end − 4, ori − 1 siz − 3 end − 4⟩),
     orth − ⟨ori − 4 siz − 4 end − 8, ori − 3 siz − 3 end − 3⟩),
     orth − ⟨ori − 9 siz − 2 end − 11, ori − 4 siz − 3 end − 7⟩))
▷DIFFN((orth − ⟨ori − 2 siz − 2 end − 4⟩),
     orth − ⟨ori − 4 siz − 4 end − 8, ori − 3 siz − 3 end − 3⟩),
     orth − ⟨ori − 9 siz − 2 end − 11, ori − 4 siz − 3 end − 7⟩))
```

*ORTHOTOPES* corresponds to the third item of the example presented at page 17.

- **Term₁ Comparison Term₂**
  - Term₁ is a term. A term is an expression that can be evaluated to one or possibly several integer values. The expressions we allow for a term are defined in the next paragraph.
  - Comparison is one of the following comparison operators ≤, ≥, <, >, =, ≠.
  - Term₂ is a term.

Let \( v_{1,1}, v_{1,2}, \ldots, v_{1,n_1} \) and \( v_{2,1}, v_{2,2}, \ldots, v_{2,n_2} \) be the values respectively associated with Term₁ and with Term₂. The restriction Term₁ Comparison Term₂ forces \( v_{1,i} \) Comparison \( v_{2,j} \) to hold for every \( i \in [1, n_1] \) and every \( j \in [1, n_2] \).

A term is one of the following expressions:

- \( c \), where \( c \) is an integer. The corresponding value is \( c \).
- \( |c| \), where \( c \) is an argument of type collection. The value of \(|c|\) is the number of items of the collection denoted by \( c \).

**EXAMPLE:** This kind of expression is used, for example, in the restrictions of the `ATLEAST(N, VARIABLES, VALUE)` constraint: \( N \leq |\text{VARIABLES}| \) restricts \( N \) to be less than or equal to the number of items of the `VARIABLES` collection.

```plaintext
▷ATLEAST(2, ⟨var − 5, var − 8, var − 5⟩, 5)
▷ATLEAST(4, ⟨var − 5, var − 8, var − 5⟩, 5)
```

- \( \text{first}(c.a) \): \( \text{first}(c.a) \) denotes the value assigned to the attribute \( a \) of the first item of the collection denoted by \( c \). It is equal to 0 if the collection is empty.
- \( \text{last}(c.a) \): \( \text{last}(c.a) \) denotes the value assigned to the attribute \( a \) of the last item of the collection denoted by \( c \). It is equal to 0 if the collection is empty.
- \( \text{sum}(c.a), \text{sum}(t) \): \( \text{sum}(c.a) \) denotes the sum of the values assigned to the attribute \( a \) of the collection denoted by \( c \). It is equal to 0 if the collection is empty.
2.2. DESCRIBING THE ARGUMENTS OF A GLOBAL CONSTRAINT

is empty: $\text{sum}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the sum of the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $\text{range}(c.a), \text{range}(\ell)$: $\text{range}(c.a)$ denotes the difference between the maximum value and the minimum value plus one of the values assigned to the attribute $a$ of the collection denoted by $c$, it is equal to 0 if the collection is empty; $\text{range}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the difference between the maximum value and the minimum value plus one of the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $\text{minval}(c.a), \text{minval}(\ell)$: $\text{minval}(c.a)$ denotes the minimum over the values assigned to the attribute $a$ of the collection denoted by $c$, it is equal to 0 if the collection is empty; $\text{minval}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the minimum over the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $\text{maxval}(c.a), \text{maxval}(\ell)$: $\text{maxval}(c.a)$ denotes the maximum over the values assigned to the attribute $a$ of the collection denoted by $c$, it is equal to 0 if the collection is empty; $\text{maxval}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the maximum over the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $\text{nval}(c.a), \text{nval}(\ell)$: $\text{nval}(c.a)$ denotes the number of distinct values over the values assigned to the attribute $a$ of the collection denoted by $c$, it is equal to 0 if the collection is empty; $\text{nval}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the number of distinct values over the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $\text{prod}(c.a), \text{prod}(\ell)$: $\text{prod}(c.a)$ denotes the product of the values assigned to the attribute $a$ of the collection denoted by $c$, it is equal to 1 if the collection is empty; $\text{prod}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the product of the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $\text{pfdc}(c.a), \text{pfdc}(\ell)$: $\text{pfdc}(c.a)$, where $\text{pfdc}$ is a pure functional dependency constraint of the form $\text{pfdc}(v, col)$ (e.g. $\text{AMONG\_DIFF\_0}, \text{PEAK}, \text{VALLEY}$) that computes a value $v$ from a collection of variables $col$, and where $c.a$ is a collection with attribute $a$ denotes the $\text{pfdc}$ of the values assigned to the attribute $a$ of the collection denoted by $c$, it is equal to 0 if the collection is empty; $\text{pfdc}(\ell)$ where $\ell$ is a list of collections attributes, each of them of the form $c_i.a_i (with i \in [1,n])$, is the $\text{pfdc}$ of the values assigned to the attributes $a_i$ of the collections denoted by $c_i (i \in [1,n])$.

- $t$, where $t$ is an argument of type $\text{int}$. The value of $t$ is the value of the corresponding argument.
2. DESCRIBING GLOBAL CONSTRAINTS

- \( v \), where \( v \) is an argument of type \( d\var \). The value of \( v \) will be the value assigned to variable \( v \).

- \( s \), where \( s \) is an argument of type \( \text{sint} \) or \( \text{svar} \). The values denoted by \( s \) are all the values of the corresponding set.

- \( c.a \), where \( c \) is an argument of type \( \text{collection} \) and \( a \) an attribute of \( c \) of type \( \text{int} \) or \( d\var \). The values denoted by \( c.a \) are all the values corresponding to attribute \( a \) for the different items of \( c \). When \( c.a \) designates a domain variable we consider the value assigned to that variable.

- \( c.a \), where \( c \) is an argument of type \( \text{collection} \) and \( a \) an attribute of \( c \) of type \( \text{sint} \) or \( \text{svar} \). The values denoted by \( c.a \) are all the values belonging to the sets corresponding to attribute \( a \) for the different items of \( c \). When \( c.a \) designates a set variable we consider the values that finally belong to that set.

---

6 Restrictions are defined on the ground instance of a global constraint.
2.2. Describing the Arguments of a Global Constraint

**Example:** This kind of expression is used, for example, in the restrictions of the INVERSE_SET(\(X, Y\)) constraint: \(X \cdot x \geq 1\) forces all items of the \(X\) collection that all the potential elements of the set variable associated with the \(x\) attribute be greater than or equal to 1.

\[ \text{Example} \rightarrow \text{INVERSE\_SET}((\text{index} - 1 \cdot x - \{2, 4\}), \text{index} - 2 \cdot x - \{4\}, \text{index} - 3 \cdot x - \{1\}, \text{index} - 4 \cdot x - \{4\}) \]

\[ \text{Example} \rightarrow \text{INVERSE\_SET}((\text{index} - 1 \cdot x - \{0, 2, 4\}, \text{index} - 2 \cdot x - \{4\}, \text{index} - 3 \cdot x - \{1\}, \text{index} - 4 \cdot x - \{4\}) \]

- \(\min(t_1, t_2)\) or \(\max(t_1, t_2)\), where \(t_1\) and \(t_2\) are terms. Let \(V_1\) and \(V_2\) denote the sets of values respectively associated with the terms \(t_1\) and \(t_2\). Let \(\min(V_1)\), \(\max(V_1)\) and \(\min(V_2)\), \(\max(V_2)\) denote the minimum and maximum values of \(V_1\) and \(V_2\). The value associated with \(\min(t_1, t_2)\) is \(\min(\min(V_1), \min(V_2))\), while the value associated with \(\max(t_1, t_2)\) is \(\max(\max(V_1), \max(V_2))\).

**Example:** This kind of expression is used, for example, in the restrictions of the NINTERVAL(\(NVAL, \text{VARIABLES}, \text{SIZE\_INTERVAL}\)) constraint: \(NVAL \geq \min(1, \text{VARIABLES})\) forces \(NVAL\) to be greater than or equal to the minimum of 1 and the number of items of the \(\text{VARIABLES}\) collection.

\[ \text{Example} \rightarrow \text{NINTERVAL}(2, (\text{var} - 3, \text{var} - 1, \text{var} - 9, \text{var} - 1, \text{var} - 9), 4) \]

\[ \text{Example} \rightarrow \text{NINTERVAL}(0, (\text{var} - 3, \text{var} - 1, \text{var} - 9, \text{var} - 1, \text{var} - 9), 4) \]

- \(t_1 \text{ op } t_2\), where \(t_1\) and \(t_2\) are terms and op one of the operators +, −, \(*)\) or \(\div\). Let \(V_1\) and \(V_2\) denote the sets of values respectively associated with the terms \(t_1\) and \(t_2\). The set of values associated with \(t_1 \text{ op } t_2\) is \(V_{12} = \{v : v = v_1 \text{ op } v_2, v_1 \in V_1, v_2 \in V_2\}\).

\(\div\) denotes an integer division, a division in which the fractional part is discarded.
2.2.4 Declaring a global constraint

Declaring a global constraint consists of providing the following information:

- A **term constraint** \((A_1, A_2, \ldots, A_n)\), where constraint corresponds to the name of the global constraint and \(A_1, A_2, \ldots, A_n\) to its arguments.

- A possibly empty **list of type declarations**, where each declaration has the form type:declaration; type is the name of the new type we define and type_declaration is a basic data type, a compound data type or a type previously defined.

- An **argument declaration** \(A_1:T_1, A_2:T_2, \ldots, A_n:T_n\) giving for each argument \(A_1, A_2, \ldots, A_n\) of the global constraint constraint its type. Each type is a basic data type, a compound data type, or a type that was declared in the list of type declarations.

EXAMPLE: This kind of expression is used, for example, in the restrictions of the RELAXED_SLI-DING_SUM(INTERFACE, ATOST, LOW, UP, SEQ, VARIABLES) constraint: ATMOST \(\leq\) |VARIABLES| − SEQ + 1 forces ATMOST to be less than or equal to an arithmetic expression that corresponds to the number of sequences of SEQ consecutive variables in a sequence of |VARIABLES| variables.

\[ \triangleright RELAXED_SLDING\_SUM(3, 4, 3, 7, 4, (\text{var} - 2, \text{var} - 4, \text{var} - 2, \text{var} - 0, \text{var} - 0, \text{var} - 3, \text{var} - 4)) \]

\[ \triangleright RELAXED_SLDING\_SUM(3, 9, 3, 7, 4, (\text{var} - 2, \text{var} - 4, \text{var} - 2, \text{var} - 0, \text{var} - 0, \text{var} - 3, \text{var} - 4)) \]

- We can use a disjunction between two restrictions.

EXAMPLE: This kind of expression is used, for example, in the Typical slot of the AMONG_LOW_UP(LOW, UP, VARIABLES, VALUES) constraint: LOW \(>\) 0 \(\lor\) UP \(<\) |VARIABLES| forces the pair LOW, UP to impose a restriction on the variables of the VARIABLES collection.\(^*\)

\[ \triangleright AMONG\_LOW\_UP(1, 2, (9, 2, 4, 5), (0, 2, 4, 6, 9)) \]

\[ \triangleright AMONG\_LOW\_UP(0, 3, (9, 2, 4, 5), (0, 2, 4, 6, 9)) \]

\[ \triangleright AMONG\_LOW\_UP(1, 4, (9, 2, 4, 5), (0, 2, 4, 6, 9)) \]

\[ \triangleright AMONG\_LOW\_UP(0, 4, (9, 2, 4, 5), (0, 2, 4, 6, 9)) \]

\(^*\)Since when both, LOW \(\leq\) 0 and UP \(\geq\) |VARIABLES|, the corresponding AMONG_LOW_UP constraint always holds.

- Finally, we can also use a constraint \(C\) of the catalogue\(^\dagger\) for expressing a restriction as long as that constraint is not defined according to the constraint under consideration. The constraint \(C\) should have a graph-based or an automaton-based description so that its meaning is explicitly defined.

EXAMPLE: An example of use of such restriction can be found in the SORT_PERMUTATION(FROM, PERMUTATION, TO) constraint: ALLDIFFERENT(PERMUTATION) is used to express that the variables of the second argument of the SORT_PERMUTATION constraint should take distinct values.

\(^\dagger\)
2.2. DESCRIBING THE ARGUMENTS OF A GLOBAL CONSTRAINT

- A possibly empty list of restrictions, where each restriction is one of the restrictions described in Section 2.2.3 on page 17.

EXAMPLE: The arguments of the ALL_DIFFER_FROM_AT_LEAST_K_POS constraint are described by:

<table>
<thead>
<tr>
<th>Constraint</th>
<th>ALL_DIFFER_FROM_AT_LEAST_K_POS(K, VECTORS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type(s)</td>
<td>VECTOR − collection(var − dvar)</td>
</tr>
<tr>
<td>Argument(s)</td>
<td>K − int</td>
</tr>
<tr>
<td></td>
<td>VECTORS − collection(vec − VECTOR)</td>
</tr>
<tr>
<td>Restriction(s)</td>
<td>required(VECTORS, vec)</td>
</tr>
<tr>
<td></td>
<td>K ≥ 0</td>
</tr>
<tr>
<td></td>
<td>same_size(VECTORS, vec)</td>
</tr>
</tbody>
</table>

The first line indicates that the ALL_DIFFER_FROM_AT_LEAST_K_POS constraint has two arguments: K and VECTORS. The second line declares a new type VECTOR, which corresponds to a collection of variables. The third line indicates that the first argument K is an integer, while the fourth line tells that the second argument VECTORS corresponds to a collection of vectors of type VECTOR. Finally the four restrictions respectively enforce that:

- All the items of the VECTOR collection mention the var attribute,
- K be greater than or equal to 0,
- All the items of the VECTORS collection mention the vec attribute,
- All the vectors have the same number of components.

2.2.5 Describing symmetries between arguments

Given a satisfied ground instance of a global constraint constraint, it is often the case that the constraint is still satisfied [129, 180] if we permute:

- Some of its arguments.
  E.g., consider the disequality constraint NEQ(X, Y), which forces X being assigned an integer value that is different from Y. Given the solution NEQ(3, 5) we can swap both arguments and still get a solution (i.e., NEQ(5, 3)).

- Items of some collections that are passed as one of its arguments.
  E.g., consider the ALLDIFFERENT(VARIABLES) constraint, which imposes all variables of the collection VARIABLES being assigned a distinct integer value. Given the solution ALLDIFFERENT(⟨5, 1, 9, 3⟩) we can swap any pair of items and still get a solution. For example, if we swap the first and fourth items we still get a solution (i.e., ALLDIFFERENT(⟨3, 1, 9, 5⟩)).

- Attributes of some items of some of its collections.
  E.g., given a collection of pairs PAIRS, where each pair has two attributes x and y, the NPAIR(N, PAIRS) constraint forces N being the number of distinct pairs in
PAIRS. Given the solution \( \text{NPAIR}(3, \langle x - 3 \, y - 1, x - 1 \, y - 5, x - 3 \, y - 1, x - 1 \, y - 5, x - 1 \, y - 3 \rangle) \) we can interchange attributes \( x \) and \( y \) and still get a solution (i.e., \( \text{NPAIR}(3, \langle x - 1 \, y - 3, x - 5 \, y - 1, x - 1 \, y - 3, x - 5 \, y - 1, x - 3 \, y - 1 \rangle) \)).

• A pair of values with respect to an attribute of some of its collections.

E.g., consider the \text{BINPACKING} constraint, which assigns items to bins in such a way that the total weight of the items in each bin does not exceed an overall fixed capacity. Each item has a bin and a weight attributes, which respectively give the bin to which the item will be assigned, and the weight of the item. Given the solution \( \text{BINPACKING}(5, \langle \text{bin} - 3 \, \text{weight} - 4, \text{bin} - 1 \, \text{weight} - 3, \text{bin} - 3 \, \text{weight} - 1 \rangle) \), we can interchange all occurrences of value 3 with all occurrences of value 1 with respect to the bin attribute. After this swap of values we get the new solution \( \text{BINPACKING}(5, \langle \text{bin} - 1 \, \text{weight} - 4, \text{bin} - 3 \, \text{weight} - 3, \text{bin} - 1 \, \text{weight} - 1 \rangle) \). This simply consists of swapping the content of two bins. Since all bins have the same capacity we still get a solution.

We provide the following moves, where each move is described by (1) an explicit fact (i.e., a meta-data), (2) a textual explanation, and (3) several concrete examples:

• \text{args(PERMUTATION)} denotes the fact that we swap the arguments of a constraint with respect to a given permutation. Arguments which are exchanged must have the same type under the hypothesis that they are ground (for example, the basic data types \text{int} and \text{dvar}, which respectively denote an integer value and a domain variable can be exchanged since a ground domain variable corresponds to an integer value). The permutation \text{PERMUTATION} is described by using standard notation, that is by providing the different cycles of the permutation.

\textbf{EXAMPLE 1:} As a first example where we can swap two arguments, consider the \text{EQ.CST(VAR1,VAR2,CST2)} constraint which, given two domain variables \( \text{VAR1}, \text{VAR2} \) and an integer value \( \text{CST2} \), forces the condition \( \text{VAR1} = \text{VAR2} + \text{CST2} \). Within the electronic catalogue this is represented by the following meta-data, \text{args}([\text{VAR1}, \text{VAR2}, \text{CST2}]), to which corresponds the following textual form:

\text{arguments are permutable w.r.t. permutation (VAR1) (VAR2, CST2)}.

Note that, even though arguments \( \text{VAR2} \) and \( \text{CST2} \) do not have the same type (i.e., \( \text{VAR2} \) is a domain variable, while \( \text{CST2} \) is an integer value), both arguments can be exchanged since we consider the ground case. For example, since \text{EQ.CST}(8, 2, 6) is satisfied, \text{EQ.CST}(8, 6, 2) is also satisfied.
EXAMPLE 2: As a second example where we can swap several arguments, consider the \texttt{COMMON(NCOMMON1, NCOMMON2, VARIABLES1, VARIABLES2)} constraint which, given two domain variables \texttt{NCOMMON1}, \texttt{NCOMMON2} and two collections of domain variables \texttt{VARIABLES1, VARIABLES2}, forces the following two conditions:

- \texttt{NCOMMON1} is the number of variables of \texttt{VARIABLES1} assigned a value in \texttt{VARIABLES2}.
- \texttt{NCOMMON2} is the number of variables of \texttt{VARIABLES2} assigned a value in \texttt{VARIABLES1}.

Within the electronic catalogue this is represented by the following meta-data, \texttt{args([[NCOMMON1, NCOMMON2], [VARIABLES1, VARIABLES2]])}, to which corresponds the following textual form:

\begin{itemize}
  \item \textit{arguments are permutable w.r.t. permutation (NCOMMON1, NCOMMON2) (VARIABLES1, VARIABLES2)}.
\end{itemize}

For example, since \texttt{COMMON(3, 4, (1, 9, 1, 5), (2, 1, 9, 9, 6, 9))} is satisfied, \texttt{COMMON(4, 3, (2, 1, 9, 9, 6, 9), (1, 9, 1, 5))} is also satisfied.

- \texttt{items(COLLECTION, PERMUTATIONS)} denotes the fact that we can permute the items of the collection \texttt{COLLECTION} with respect to a permutation belonging to a given set of permutations \texttt{PERMUTATIONS}:

  - \texttt{COLLECTION} stands for one of the following:
    \begin{enumerate}
      \item An argument \texttt{ARG} of the global constraint that corresponds to a \texttt{collection} of items.
      \item A term \texttt{ARG.attr}, where \texttt{attr} is an attribute of a \texttt{collection} of items that is an argument \texttt{ARG} of the global constraint; in addition, the type of \texttt{attr} is itself a collection. Given a collection \texttt{ARG} of \texttt{n} items \texttt{\{ARG[1], ARG[2], ..., ARG[n]\}}, a permutation of \texttt{PERMUTATIONS}, \textit{not necessarily the same}, is applied on the items of a subset of the set of collections \texttt{\{ARG[1].attr, ARG[2].attr, ..., ARG[n].attr\}}.
    \end{enumerate}

  - \texttt{PERMUTATIONS} represents a set of permutations. It can take one of the following values:

    \begin{enumerate}
      \item \texttt{all} stands for all possible permutations. Note that this case is a little artificial since it does not really correspond to a symmetry of the constraint, but rather to the use of a collection for representing a set of variables. But, to our best knowledge in 2010, concrete solvers do also not use sets of variables but rather collections, lists or arrays of variables.
      \item \texttt{reverse} stands for the set that only contains the permutation that maps the sequence \texttt{e1, e2, ..., en} to \texttt{en, en-1, ..., e1}.
      \item \texttt{shift} stands for the set that only contains the permutation that maps the sequence \texttt{e1, e2, ..., en} to \texttt{en, e1, ..., en-1}.
    \end{enumerate}
EXAMPLE 1: As a first example, consider the **ALLDIFFERENT**(VARIABLES) constraint, which has a single argument corresponding to a collection of variables which must all be assigned distinct values. Within the electronic catalogue this is represented by the following meta-data, **items**(VARIABLES, all), to which corresponds the following textual form:

**items of VARIABLES are permutable.**

For example, since **ALLDIFFERENT**(⟨1, 4, 9⟩) is satisfied, all permutations of ⟨1, 4, 9⟩ (i.e., ⟨1, 4, 9⟩, ⟨1, 9, 4⟩, ⟨4, 1, 9⟩, ⟨4, 9, 1⟩, ⟨9, 1, 4⟩, ⟨9, 4, 1⟩) correspond to valid solutions to the **ALLDIFFERENT** constraint.

EXAMPLE 2: As a second example, consider the **K SAME**(SETS) constraint, which has a single argument corresponding to a collection of sets, where each set is a collection of domain variables that must be assigned the same set of values (i.e., **K SAME** forces an equality between multisets). The argument **SETS** is a collection, where each item consists of a single set attribute. The type of a set attribute is a collection of domain variables. Within the electronic catalogue this is represented by the following meta-data, **items**(SETS.set, all), to which corresponds the following textual form:

**items of SETS.set are permutable.**

For example, since **K SAME**(⟨set − ⟨1, 4, 4⟩, set − ⟨4, 4, 1⟩, set − ⟨1, 4, 4⟩⟩) is satisfied, it is also satisfied for all permutations of the elements of its second set ⟨4, 4, 1⟩, i.e.:

- **K SAME**(⟨set − ⟨1, 4, 4⟩, set − ⟨1, 4, 4⟩, set − ⟨1, 4, 4⟩⟩).
- **K SAME**(⟨set − ⟨1, 4, 4⟩, set − ⟨4, 1, 4⟩, set − ⟨1, 4, 4⟩⟩).
- **K SAME**(⟨set − ⟨1, 4, 4⟩, set − ⟨4, 4, 1⟩, set − ⟨1, 4, 4⟩⟩).

- **items_sync**(COLLECTIONS, PERMUTATIONS) denotes the fact that we can permute the items of several collections **COLLECTIONS** with respect to a permutation belonging to a given set of permutations **PERMUTATIONS** in such a way that *one and the same permutation is used on all collections* (i.e., therefore the keyword **items_sync** which stands for **items synchronisation**):

  - **COLLECTIONS** stands for a non-empty list of terms of the form **ARG** or **ARG.attr**, where **ARG** is an argument of the global constraint that corresponds to a collection, and **attr** is an attribute of **ARG** such that its type is itself a collection. In addition, we also have the following restrictions:

    1. If **COLLECTIONS** contains a single element then this element has the form **ARG.attr**. This is done to allow to designate more than a single collection.

    2. All collections designated by **COLLECTIONS** have the same type as well as the same number of items.

    The *same permutation* of **PERMUTATIONS** is applied on the items of the different collections referenced by **COLLECTIONS**.

  - As for the symmetry keyword **items**, **PERMUTATIONS** represents a set of permutations. It can take the same set of values as before, namely:

    1. *all stands for all possible permutations.*
2.2. DESCRIBING THE ARGUMENTS OF A GLOBAL CONSTRAINT

2. `reverse` stands for the set that only contains the permutation that maps the sequence \( e_1, e_2, \ldots, e_n \) to \( e_n, e_{n-1}, \ldots, e_1 \).

3. `shift` stands for the set that only contains the permutation that maps the sequence \( e_1, e_2, \ldots, e_n \) to \( e_n, e_1, \ldots, e_{n-1} \).

**EXAMPLE 1:** As a first example, consider the `CONSECUTIVE_GROUPS_OF_ONES(GROUP_SIZES, VARIABLES)` constraint, which has two arguments `GROUP_SIZES` and `VARIABLES` respectively corresponding to a collection of positive integers and to a collection of 0-1 domain variables. The constraint imposes that the \( m \) successive maximum groups of consecutive ones of `VARIABLES` have sizes `GROUP_SIZES[1]`, `GROUP_SIZES[2]`, \( \ldots \), `GROUP_SIZES[m]`. Note that, if we reverse the items of both `GROUP_SIZES` and `VARIABLES`, we still have a solution. Within the electronic catalogue this is represented by the following meta-data, `items_sync([GROUP_SIZES, VARIABLES], reverse)`, to which corresponds the following textual form:

*items of `GROUP_SIZES` and `VARIABLES` are simultaneously reversible.*

For example, since `CONSECUTIVE_GROUPS_OF_ONES([2, 1], [1, 1, 0, 0, 0, 1, 0])` is a solution, `CONSECUTIVE_GROUPS_OF_ONES([1, 2], [0, 1, 0, 0, 0, 1, 1])` is also a valid solution.

**EXAMPLE 2:** As a second example, consider the `NVECTOR(NVEC, VECTORS)` constraint, which has two arguments `NVEC` and `VECTORS` respectively corresponding to a domain variable and to a collection of collections of domain variables, where all collections have the same number of items. The unique attribute of `VECTORS` is denoted by `vec` and its type is a collection of domain variables. Each collection is interpreted as a vector and two vectors are distinct if and only if they differ in at least one component. The `NVECTOR` constraint forces `NVEC` to be equal to the number of distinct vectors within `VECTORS`. If we permute the components of all vectors with respect to a same permutation we still have the same number of distinct vectors. Within the electronic catalogue this is represented by the following meta-data, `items_sync([VECTORS, vec], all)`, to which corresponds the following textual form:

*items of `VECTORS, vec` are permutable (same permutation used).*

For example, since `NVECTOR(2, [vec – {1, 1, 8}, vec – {5, 1, 6}, vec – {1, 1, 8}])` is a solution, any permutation applied simultaneously to the three components of each vector leads to a solution, i.e.:

- `NVECTOR(2, [vec – {1, 1, 8}, vec – {5, 1, 6}, vec – {1, 1, 8}])`,
- `NVECTOR(2, [vec – {1, 8, 1}, vec – {5, 6, 1}, vec – {1, 8, 1}])`,
- `NVECTOR(2, [vec – {1, 1, 8}, vec – {1, 5, 6}, vec – {1, 1, 8}])`,
- `NVECTOR(2, [vec – {1, 8, 1}, vec – {1, 6, 5}, vec – {1, 8, 1}])`,
- `NVECTOR(2, [vec – {8, 1, 1}, vec – {6, 1, 5}, vec – {8, 1, 1}])`,
- `NVECTOR(2, [vec – {8, 1, 1}, vec – {6, 5, 1}, vec – {8, 1, 1}])`.

*attrs(COLLECTION, PERMUTATION)* denotes the fact that we can permute the attributes of the collection `COLLECTION`, not necessarily all items, with respect to a permutation `PERMUTATION`. Attributes that are exchanged must have the same type under the hypothesis that they are ground (e.g., an attribute `attr1` of type `int` can be exchanged with an attribute `attr2` of type `dvar`).
2. DESCRIBING GLOBAL CONSTRAINTS

**EXAMPLE:** As an example, consider the `SCALAR_PRODUCT(LINEARTERM, CTR, VAL)` constraint, which forces a linear term, represented by a collection with two attributes `coeff` and `var`, to be equal, different, less, greater than or equal, greater, or less than or equal (i.e., depending on the value of `CTR`) to `VAL`. In the ground case we can exchange attributes `coeff` and `var` without affecting the fact the constraint is satisfied. Within the electronic catalogue this is represented by the following meta-data, `attrs[LINEARTERM, [[coeff, var]]]`, to which corresponds the following textual form:

attributes of LINEARTERM are permutable w.r.t. permutation (coeff, var)

(permutation not necessarily applied to all items).

For example, since `SCALAR_PRODUCT((coeff - 1 var - 1, coeff - 3 var - 1, coeff - 1 var - 4,), =, 8)` is a solution, `SCALAR_PRODUCT((coeff - 1 var - 1, coeff - 1 var - 3, coeff - 1 var - 4,), =, 8)` is also a valid solution (i.e., the attributes `coeff` and `var` of the second item were permuted).

- **attrs_sync(COLLECTION, PERMUTATION)** denotes the fact that we can permute the attributes of the collection COLLECTION, necessarily all items, with respect to a permutation PERMUTATION. As before, attributes that are exchanged must have the same type under the hypothesis that they are ground.

**EXAMPLE:** As an example, consider the `CROSSING(NCROSS, SEGMENTS)` constraint, which forces `NCROSS` to be equal to the number of line segments intersections between the line segments defined by the `SEGMENTS` collection. Each line segment is defined by the coordinates `(ox, oy)` and `(ex, ey)` of its two extremities. Note that we can exchange the role of the `x` and `y` axes without affecting the number of line segments intersections. Within the electronic catalogue this is represented by the following meta-data, `attrs_sync(SEGMENTS, [[ox, oy], [ex, ey]])`, to which corresponds the following textual form:

attributes of SEGMENTS are permutable w.r.t. permutation (ox, oy) (ex, ey)

(permutation applied to all items).

For example, since `CROSSING(3, (ox - 1 oy - 4 ex - 9 ey - 2, ox - 1 oy - 1 ex - 3 ey - 5, ox - 3 oy - 2 ex - 7 ey - 4, ox - 9 oy - 1 ex - 9 ey - 4))` is a solution, `CROSSING(3, (ox - 4 oy - 1 ex - 2 ey - 9, ox - 1 oy - 1 ex - 5 ey - 3, ox - 2 oy - 3 ex - 4 ey - 7, ox - 1 oy - 9 ex - 4 ey - 9))` is also a valid solution.

- **vals(ATTRIBUTES, PARTITION, PAIRS, SOURCE, TARGET)** denotes the fact that we can permute some source value with some distinct target value. The kind of value permutation we can perform is parameterised by five parameters:

  - ATTRIBUTES is a list of paths of the form `ARG0 or ARG1. . . . ARGn.attr` (n ≥ 1), where:
    * `ARG0` is an argument of the global constraint of type `domain variable`, `integer`, or collection of `domain variables` or `integers`.
    * `ARG1. . . . ARGn.attr` is a path to an integer attribute or to a collection of integers attribute of the global constraint. `ARG1, ARG2, . . . , ARGn` are collections and `attr` is an attribute of `ARGn` of type `domain variable`, `integer`, or collection of `domain variables` or `integers`. In this last context, all collections have the same number of items since we can only
exchange tuples of values that have the same number of components. The path does not necessarily start from a top level collection.

Its purpose is to define the scope where the exchange of values, or tuples of values, will take place. Note that:

* The case corresponding to \( \text{ARG}_0 \) allows to express the fact the value of an integer argument can be changed in such a way that we still have a solution.
* The case when \( \text{ARG}_1 \) is not a top level collection allows to express the fact the exchange of value takes place within a nested collection. In this context this implicitly defines several scopes for the exchange of values.
* The case where \( \text{ARG}_1 \cdots \text{ARG}_n.\text{attr} \) is a path to a collection of variables or integers allows expressing swap between tuples of values (i.e., the exchange of values is generalised to the exchange of tuples of values).

PARTITION usually defines a partition \( P \) of integer values. Only when \( \text{ARG}_1 \cdots \text{ARG}_n.\text{attr} \) is a path to a collection of variables or integers, PARTITION defines a partition of tuples of integer values. For the time being we focus on the first case, i.e., a partition of integer values. Its aim is to define classes of values from which the source and target values will be selected. In order to define a partition \( P \) we first introduce the notion of set of values generator. Within these definitions, \( u \) and \( v \) both denote (1) an integer value, or (2) an argument of the constraint of type integer or domain variable, or (3) a term of the form \( |\text{ARG}| \) where \( \text{ARG} \) is an argument of type collection denoting the number of items of the collection, (4) a sum or difference of elements of the form (1), (2) or (3). We have two kinds of generators, namely:

* A basic set of values generator is defined by one of those:
  * \( \text{ARG} . \text{attr} \), where \( \text{ARG} \) is an argument of type collection and \( \text{attr} \) is an attribute of \( \text{ARG} \) of type integer or domain variable, denotes the set of all values assigned to \( \text{ARG} . \text{attr} \).
  * \( \text{notin} (\text{ARG} . \text{attr}) \), where \( \text{ARG} \) is an argument of type collection and \( \text{attr} \) is an attribute of \( \text{ARG} \) of type integer or domain variable, denotes the set of all elements of \( \mathbb{Z} \) that are not assigned to \( \text{ARG} . \text{attr} \).
  * \( \text{diff} (\text{ARG}_1 . \text{attr}_1, \text{ARG}_2 . \text{attr}_2) \), where \( \text{ARG}_1 \) (respectively \( \text{ARG}_2 \)) is an argument of type collection and \( \text{attr}_1 \) (respectively \( \text{attr}_2 \)) is an attribute of \( \text{ARG}_1 \) (respectively \( \text{ARG}_2 \)) of type integer or domain variable, denotes the set of all elements of \( \mathbb{Z} \) that are assigned to \( \text{ARG}_1 . \text{attr}_1 \) but not to \( \text{ARG}_2 . \text{attr}_2 \).
  * \( u \), denotes the set \( \{u\} \).
  * \( \text{cmp}(u), (\text{cmp} \in \{=, \neq, <, \geq, >, \leq\}) \), denotes the set of all integers \( e \) such that the comparison \( e \text{ cmp } u \) holds.
2. DESCRIBING GLOBAL CONSTRAINTS

- \( \text{in}(u, v), (u \leq v) \), denotes the set of all integers located in interval \([u, v]\).
- \( \text{notin}(u, v), (u \leq v) \), denotes the set of all integers not located in interval \([u, v]\).
- \( \text{mod}(u, v), (0 < v < u, u, v \in \mathbb{N}^+) \), denotes all integer values in \(\mathbb{Z}\) that have \(v\) as remainder when divided by \(u\).\(^8\)

* Given set of values generators \(S_1, S_2, \ldots, S_n\) \((n \geq 2)\), a compound set of values generator is defined by:
  - \([S_1, S_2, \ldots, S_n]\) denotes all values that are in at least one of the sets \(S_1, S_2, \ldots, S_n\).
  - \(\text{notin}([S_1, S_2, \ldots, S_n])\) denotes all values of \(\mathbb{Z}\) that are not in any set \(S_1, S_2, \ldots, S_n\).

We now describe the different partition generators. Within the description, \(S\) and \(D\) denote set of values generators. Classes of a partition are ordered. Unless explicitly specified, classes are ordered with respect to the smallest element they contain.

* \(\text{int}\) denotes a partition \(P\) where, to each element of \(\mathbb{Z}\) corresponds a specific class of \(P\) containing just that element.
* \(\text{int}(S)\) denotes a partition \(P\) where, to each element of \(S\) corresponds a specific class of \(P\) containing just that element.
* \(\text{all}\) denotes a partition \(P\) containing a single class of values corresponding to all integer values in \(\mathbb{Z}\).
* \(\text{all}(S)\) denotes a partition \(P\) containing a single class of values corresponding to the elements of \(S\).
* \(\text{comp}(S)\) denotes of partition \(P\) containing two classes of values: a first class corresponding to the elements of \(S\), and a second class consisting of all elements of \(\mathbb{Z}\) that are not in \(S\).
* \(\text{comp.diff}(S, D)\) denotes of partition \(P\) containing two classes of values: a first class corresponding to the elements of \(S\) but not in \(D\), and a second class consisting of all elements of \(\mathbb{Z}\) that are neither in \(S\) nor in \(D\).
* \(\text{intervals}(u), (u > 0)\), denotes a partition \(P\) containing intervals of the form \([k \cdot u, k \cdot u + u - 1], k \in \mathbb{Z}\).
* \(\text{mod}(u), (u > 0)\), denotes a partition \(P\) such that each class of \(P\) is made up from all integers in \(\mathbb{Z}\) that have the same remainder when divided by \(u\).\(^9\)
* \(\text{part}(P)\), where \(P\) is a collection of collections of integers passed as one of the arguments of the constraint, where each integer occurs once, denotes a partition \(P\) such that each class corresponds to the elements of one of the collections of \(P\). Classes are ordered with respect to their occurrences in \(P\).

\(^8\)remainder\((a, n) = a - n \lfloor \frac{a}{n} \rfloor\).
\(^9\)remainder\((a, n) = a - n \lfloor \frac{a}{n} \rfloor\).
When \( \text{PARTITION} \) defines a partition of tuples, where each tuple consists of \( k \) integers, \( \text{PARTITION} \) can only be set to \( \text{int} \). In this context \( \text{int} \) denotes a partition \( \mathcal{P} \) where, to each element of \( \mathbb{Z}^k \) corresponds a specific class of \( \mathcal{P} \) containing just that element.

- \( \text{PAIRS} \) is one of the symbols \( \neq, =, <, \geq, >, \leq, \text{or} \text{dontcare} \). It specifies a set of pairs \( \{(p_{i_1}, p_{j_1}), (p_{i_2}, p_{j_2}), \ldots, (p_{i_n}, p_{j_n})\} \) of elements of the partition \( \mathcal{P} \) such that, when \( \text{PAIRS} \) is different from \( \text{dontcare} \), the condition \( i_k \text{PAIRS} j_k \) holds for all \( k \in [1,n] \). The aim of the \( \text{PAIRS} \) parameter is to allow to specify which partitions of \( \mathcal{P} \) the source value \( u \) and the target value \( v \) should belong to. In fact there should exist a pair \( (p_{i_k}, p_{j_k}) \), \( (k \in [1,n]) \), such that \( u \in p_{i_k} \) and \( v \in p_{j_k} \).

- \( \text{SOURCE} \) is one of the options \( \text{all} \) or \( \text{dontcare} \):
  * When set to \( \text{all} \) it indicates that all occurrences of the source value should be replaced by the target value. All occurrences of the target value, if it is used, should also be replaced by the source value.
  * When set to \( \text{dontcare} \) it tells that not necessarily all occurrences of the source value should be replaced. The target value is left unchanged.

- \( \text{TARGET} \) is one of the options \( \text{in} \) or \( \text{dontcare} \):
  * When set to \( \text{in} \) it indicates that the target value should correspond to an already existing value of \( \text{ARG.attr} \).
  * When set to \( \text{dontcare} \) it tells that the target value can either correspond to an already existing value of \( \text{ARG.attr} \), or designate a new value.

We now define the set of conditions we must have in order to exchange a source and a target values. Consider,

1. a ground instance of a global constraint \( C \),
2. a path \( \text{PATH} \) that designates either an argument of type integer, or an integer attribute of a collection that occurs, possibly in a nested way, as one of the arguments of \( C \),
3. the sets of values \( \mathcal{V}_1, \mathcal{V}_2, \ldots, \mathcal{V}_h \) that are assigned to \( \text{PATH} \) in the ground instance of \( C \),
4. a partition of integer values \( \mathcal{P} \) derived from \( \text{PARTITION} \),
5. a set of pairs \( \{(p_{i_1}, p_{j_1}), (p_{i_2}, p_{j_2}), \ldots, (p_{i_n}, p_{j_n})\} \) of elements of the partition \( \mathcal{P} \) such that the condition \( \text{PAIRS} = \text{dontcare} \lor i_k \text{PAIRS} j_k \) holds for all \( k \in [1,n] \),
6. a \( \text{TARGET} \) option.

Given one of the sets of values \( \mathcal{V}_\alpha \), \( (1 \leq \alpha \leq h) \), a source value \( u \) can be permuted with a target value \( v \) if and only if the following conditions are all satisfied:

---

\(^{10}\)When \( \text{PAIRS} \) is equal to \( \text{dontcare} \) we just consider all possible pairs.

\(^{11}\)We may have more than one set when the path does not start from a top level collection.
1. \( u \neq v \) (source and target values should be distinct),
2. \( u \in \mathcal{V}_o \) (source value, i.e., value that is replaced, should be part of the solution),
3. \( \exists k | u \in \mathcal{P}_{ik} \land v \in \mathcal{P}_{jk} \) (source and target values should be located in the appropriate partition classes),
4. \( \text{TGT} = \text{in} \Rightarrow v \in \mathcal{V}_o \) (if \( \text{TGT} = \text{in} \) then the target value should also be part of the solution).

If \( \text{SOURCE} \) is equal to \( \text{all} \) we replace each occurrence of \( u \) by \( v \), and conversely each occurrence of \( v \) by \( u \). Otherwise we replace at least one occurrence of \( u \) by \( v \).

Without loss of generality, when \( \text{PATH} \) designates a collection of integer values or domain variables, the exchange of tuples of values is defined in a similar way.

We now provide a number of examples of value symmetry and illustrate how to encode them with the five parameters we just introduced. We start from the most common value symmetry, namely exchanging all occurrences of two distinct values or replacing all occurrences of a value by an unused value.

---

**EXAMPLE 1:** As a first example, consider the \texttt{ALLDIFFERENT}(\texttt{VARIABLES}) constraint, which forces all variables of the collection \texttt{VARIABLES} to take distinct values. Note that we can exchange two assigned values of \texttt{VARIABLES}, or replace an assigned value of \texttt{VARIABLES} by a new value, i.e., a value that is not yet assigned to any variable of \texttt{VARIABLES}. Within the electronic catalogue this is represented by

\[
\text{vals}(\texttt{VARIABLES.var}, \texttt{int}, \neq, \texttt{all}, \texttt{dontcare}),
\]

which corresponds to the following textual form:

*Two distinct values of \texttt{VARIABLES.var} can be swapped; a value of \texttt{VARIABLES.var} can be renamed to any unused value.*

For example, since \texttt{ALLDIFFERENT}(\langle 5, 1, 9, 3 \rangle) is a solution, we can replace value 9 by a not yet assigned value 0, for instance, and get another valid solution \texttt{ALLDIFFERENT}(\langle 5, 1, 0, 3 \rangle).

The five parameters of \texttt{vals}(\texttt{VARIABLES.var}, \texttt{int}, \neq, \texttt{all}, \texttt{dontcare}) have the following meaning:

- \texttt{VARIABLES.var} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
- \texttt{int} defines the partition of values \( \mathcal{P} = \ldots, \{\text{-1}\}, \{0\}, \{1\}, \ldots \)
- \( \neq \) indicates that the exchange of values takes place between two distinct elements of \( \mathcal{P} \).
- \texttt{all} specifies that all occurrences of the source value have to be exchanged with all occurrences of the target value.
- \texttt{dontcare} tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in \texttt{VARIABLES.var}.  

EXAMPLE 2: As a second example, consider the \texttt{NVALUE(NVAL, VARIABLES)} constraint, which forces \texttt{NVAL} to be equal to the number of distinct values assigned to the variables of the collection \texttt{VARIABLES}. Note that we can exchange all occurrences of two distinct values of \texttt{VARIABLES}, or replace all occurrences of an assigned value of \texttt{VARIABLES} by a new value, i.e., a value that is not yet assigned to any variable of \texttt{VARIABLES}. Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES.var], int, \neq, all, dontcare)}, to which corresponds the following textual form:

\textit{All occurrences of two distinct values of VARIABLES.var can be swapped; all occurrences of a value of VARIABLES.var can be renamed to any unused value.}

For example, since \texttt{NVALUE(4, \langle3, 1, 7, 1, 6\rangle)} is a solution, we can replace all occurrences of value 1 by a not yet assigned value 8, for instance, and get another valid solution \texttt{NVALUE(4, \langle3, 8, 7, 8, 6\rangle)}. We can also swap all occurrences of value 1 and value 3, and get another valid solution \texttt{NVALUE(4, \langle1, 3, 7, 3, 6\rangle)}.

The five parameters of \texttt{vals([VARIABLES.var], int, \neq, all, dontcare)} have the following meaning:

- \texttt{[VARIABLES.var]} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
- \texttt{int} defines the partition of values \( P = \ldots \{-1\}, \{0\}, \{1\}, \ldots \)
- \texttt{\neq} indicates that the exchange of values takes place between two distinct elements of \( P \).
- \texttt{all} specifies that all occurrences of the source value have to be exchanged with all occurrences of the target value.
- \texttt{dontcare} tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in \texttt{VARIABLES.var}.

We now introduce a third and a fourth example where the meta-data used for describing value symmetry, \texttt{vals([VARIABLES.var], int, \neq, all, dontcare)}, is replaced by \texttt{vals([VARIABLES.var], int, \neq, all, in)}, i.e., we are not allowed to introduce an unused value.
2. DESCRIBING GLOBAL CONSTRAINTS

EXAMPLE 3: As a third example, consider the \texttt{ALL_MIN_DIST(MINDIST, VARIABLES)} constraint, which forces for each pair \((\texttt{var}_i, \texttt{var}_j)\) of distinct variables of the collection \texttt{VARIABLES} that \(|\texttt{var}_i - \texttt{var}_j| \geq \text{MINDIST}\). Note that we can exchange two occurrences of distinct values of \texttt{VARIABLES}, but we cannot replace an existing value \(u\) by a new value \(v\) (since the new value \(v\) may be too close from another existing value \(w\), i.e., \(|v - w| < \text{MINDIST}\)). Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES.var], int, \neq, all, in)}, to which corresponds the following textual form:

\begin{itemize}
  \item \texttt{[VARIABLES.var]} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
  \item \texttt{int} defines the partition of values \(P = \ldots, \{-1\}, \{0\}, \{1\}, \ldots\).
  \item \(\neq\) indicates that the exchange of values takes place between two distinct elements of \(P\).
  \item \texttt{all} specifies that all occurrences of the source value have to be exchanged with all occurrences of the target value.
  \item \texttt{in} tells that the source value has to be replaced by an already existing value in \texttt{VARIABLES.var}.
\end{itemize}

EXAMPLE 4: As a fourth example, consider the \texttt{MINIMUM(MIN, VARIABLES)} constraint, which forces \texttt{MIN} to be equal to the minimum value of the collection \texttt{VARIABLES}. Note that we can exchange all occurrences of two distinct values of \texttt{VARIABLES}, but we cannot replace an existing value \(u\) by a new value \(v\) (since the new value \(v\) may be smaller than \texttt{MIN}). Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES.var], int, \neq, all, in)}, to which corresponds the following textual form:

\begin{itemize}
  \item \texttt{[VARIABLES.var]} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
  \item \texttt{int} defines the partition of values \(P = \ldots, \{-1\}, \{0\}, \{1\}, \ldots\).
  \item \(\neq\) indicates that the exchange of values takes place between two distinct elements of \(P\).
  \item \texttt{all} specifies that all occurrences of the source value have to be exchanged with all occurrences of the target value.
  \item \texttt{in} tells that the source value has to be replaced by an already existing value in \texttt{VARIABLES.var}.
\end{itemize}

We now present three examples where, using the partition generator \(\texttt{comp}(\mathcal{S})\),
we consider two classes of values: a first class consisting of elements of \( S \) and a second class of elements of \( Z \) not in \( S \). The first example corresponds to a value symmetry where values from the same class are exchanged, while the two other examples consider permutation of values between distinct classes with respect to a given class ordering.

EXAMPLE 5: As a fifth example, consider the \texttt{AMONG}(\texttt{NVAR}, \texttt{VARIABLES}, \texttt{VALUES}) constraint, which forces \texttt{NVAR} to be equal to the number of variables of the collection \texttt{VARIABLES} that are assigned a value in \texttt{VALUES}. We focus on exchanges of values that take place within \texttt{VARIABLES}. Note that, given a value that both occurs in \texttt{VARIABLES} and in \texttt{VALUES}, we can replace it by any value in \texttt{VALUES}. But we can also replace a value that occurs in \texttt{VARIABLES}, but not in \texttt{VALUES}, by any value not in \texttt{VALUES}. Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES.var], comp(VALUES.val), =, dontcare, dontcare)}, to which corresponds the following textual form:

\begin{quote}
An occurrence of a value of \texttt{VARIABLES.var} that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).
\end{quote}

For example, since \texttt{AMONG}(3, \langle 4, 5, 5, 4, 1 \rangle, \langle 1, 5, 8 \rangle) is a solution, we can swap the first occurrence of value 5 with the second occurrence of value 4 in \texttt{VARIABLES.var}, and get another valid solution \texttt{AMONG}(3, \langle 4, 4, 5, 5, 1 \rangle, \langle 1, 5, 8 \rangle).

The five parameters of \texttt{vals([VARIABLES.var], comp(VALUES.val), =, dontcare, dontcare)} have the following meaning:

\begin{itemize}
  \item \texttt{[VARIABLES.var]} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
  \item \texttt{comp(VALUES.val)} defines two sets of values, a first set \( S_1 \) corresponding to all values in \texttt{VALUES.val}, and a second set \( S_2 \) corresponding to all values not in \texttt{VALUES.val}.
  \item \texttt{= \texttt{index}} indicates that the exchange of values takes place within the same set, i.e., within \( S_1 \) or within \( S_2 \).
  \item \texttt{dontcare} specifies that one occurrence of the source value has to be replaced by the target value.
  \item \texttt{dontcare} tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in \texttt{VARIABLES.var}.
\end{itemize}
EXAMPLE 6: As a sixth example, consider the \texttt{ATLEAST(N,VARIABLES,VALUE)} constraint, which forces at least \( N \) variables of the collection \texttt{VARIABLES} to be assigned value \texttt{VALUE}. Note that, given an occurrence of value that belongs to \texttt{VARIABLES} that is different from \texttt{VALUE}, we can replace it by any other value that is also different from \texttt{VALUE}. But we can also replace it by value \texttt{VALUE} since this does not decrease the number of variables that are assigned value \texttt{VALUE}. Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES.var],comp(VALUE),\geq,dontcare,dontcare)}, to which corresponds the following textual form:

\begin{quote}
An occurrence of a value of \texttt{VARIABLES.var} that is different from \texttt{VALUE} can be replaced by any other value.
\end{quote}

For example, since \texttt{ATLEAST(2,\langle4,2,4,5,2\rangle,4)} is a solution, we can replace the second occurrence of value 2 with a value that is different from value 4, e.g., value 8, and get another valid solution \texttt{ATLEAST(2,\langle4,2,4,5,8\rangle,4)}. We can also replace the second occurrence of value 2 with value 4 and get another valid solution \texttt{ATLEAST(2,\langle4,2,4,5,4\rangle,4)}. The five parameters of \texttt{vals([VARIABLES.var],comp(VALUE),\geq,dontcare,dontcare)} have the following meaning:

- [\texttt{VARIABLES.var}] indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
- \texttt{comp(VALUE)} defines two set of values, a first set \( S_1 \) containing only value \texttt{VALUE}, and a second set \( S_2 \) corresponding to all values different from \texttt{VALUE}.
- \texttt{\geq} indicates that the the source and target values should respectively belong to sets \( S_i \) and \( S_j \) where \( i \geq j \):
  1. If the source value is different from \texttt{VALUE} (i.e., the source value belongs to \( S_2 \)), then the target value can indifferently be equal or not equal to \texttt{VALUE} (i.e., the target value belongs to \( S_1 \) or \( S_2 \)).
  2. If the source value is equal to \texttt{VALUE} (i.e., the source value belongs to \( S_1 \)), then the target value is equal to \texttt{VALUE} (i.e., the target value also belongs to \( S_1 \)). But in this case no exchange can take place since the source and target values are identical.
- \texttt{dontcare} specifies that one occurrence of the source value has to be replaced by the target value.
- \texttt{dontcare} tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in \texttt{VARIABLES.var}.

\footnote{Within the collection \texttt{VARIABLES}, this swap does not change the number of variables that are assigned value \texttt{VALUE}.}
EXAMPLE 7: As a seventh example, consider the \texttt{ATMOST}(N, VARIABLES, VALUE) constraint, which forces at most \(N\) variables of the collection \texttt{VARIABLES} to be assigned value \texttt{VALUE}. Note that, given an occurrence of value that belongs to \texttt{VARIABLES}, and that is different from \texttt{VALUE}, we can replace it by any other value that is also different from \texttt{VALUE}. But we can also replace an occurrence of value \texttt{VALUE} by a value that is different from \texttt{VALUE}, since this does not increase the number of variables that are assigned value \texttt{VALUE}. Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES.var], comp(VALUE), \leq, dontcare, dontcare)}, to which corresponds the following textual form:

An occurrence of a value of \texttt{VARIABLES.var} can be replaced by any other value that is different from \texttt{VALUE}.

For example, since \texttt{ATMOST}(1, \langle 4, 2, 4, 5 \rangle, 2) is a solution, we can replace the second occurrence of value 4 with a value that is different from value 2, e.g., value 8, and get another valid solution \texttt{ATMOST}(1, \langle 4, 2, 8, 5 \rangle, 2). But, within \texttt{ATMOST}(1, \langle 4, 2, 4, 5 \rangle, 2), we can also replace value 2 with any other value, e.g. value 4 and get another valid solution \texttt{ATMOST}(1, \langle 4, 4, 4, 5 \rangle, 2).

The five parameters of \texttt{vals([VARIABLES.var], comp(VALUE), \leq, dontcare, dontcare)} have the following meaning:

- \texttt{[VARIABLES.var]} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES} collection.
- \texttt{comp(VALUE)} defines two set of values, a first set \(S_1\) containing only value \texttt{VALUE}, and a second set \(S_2\) corresponding to all values different from \texttt{VALUE}.
- \texttt{\leq} indicates that the the source and target values should respectively belong to sets \(S_i\) and \(S_j\) where \(i \leq j\):
  1. If the source value is different from \texttt{VALUE} (i.e., the source value belongs to \(S_2\)), then the target value is also different from \texttt{VALUE} (i.e., the target value belongs to \(S_2\)). This supports the fact that we do not want to increase the number of occurrences of value \texttt{VALUE}.
  2. If the source value is equal to \texttt{VALUE} (i.e., the source value belongs to \(S_1\), then there is no restriction on the target value (i.e., the target value belongs to \(S_1\) or to \(S_2\)). But the set \(S_1\) is not relevant since the target value would also be fixed to \texttt{VALUE}, and, in this context, no exchange can take place.
- \texttt{dontcare} specifies that one occurrence of the source value has to be replaced by the target value.
- \texttt{dontcare} tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in \texttt{VARIABLES.var}.

\footnote{Within the collection \texttt{VARIABLES}, this swap does not change the number of variables that are assigned value \texttt{VALUE}.}

We now illustrate the fact the scope of value symmetry can sometimes be extended to several collections of variables. For this purpose we consider the \texttt{COMMON} constraint.
EXAMPLE 8: Consider the \texttt{COMMON(NCOMMON1, NCOMMON2, VARIABLES1, VARIABLES2)} constraint, which forces the two following conditions:

- \texttt{NCOMMON1} is the number of variables of the collection \texttt{VARIABLES1} taking a value in \texttt{VARIABLES2}.
- \texttt{NCOMMON2} is the number of variables of the collection \texttt{VARIABLES2} taking a value in \texttt{VARIABLES1}.

Note that we can exchange all occurrences of two distinct values of \texttt{VARIABLES1} or \texttt{VARIABLES2}, or replace all occurrences of an assigned value of \texttt{VARIABLES1} or \texttt{VARIABLES2} by a new value, i.e., a value that is not yet assigned to any variable of \texttt{VARIABLES1} and \texttt{VARIABLES2}. Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([VARIABLES1.var, VARIABLES2.var], int, \neq, all, dontcare)}, to which corresponds the following textual form:

\begin{quote}
All occurrences of two distinct values in \texttt{VARIABLES1.var} or \texttt{VARIABLES2.var} can be swapped; all occurrences of a value in \texttt{VARIABLES1.var} or \texttt{VARIABLES2.var} can be renamed to any unused value.
\end{quote}

For example, since \texttt{COMMON(3, 4, \langle 1, 9, 1, 5 \rangle, \langle 2, 1, 9, 9, 6, 9 \rangle)} is a solution, we can replace all occurrences of value 1 by a not yet assigned value 7, for instance, and get another valid solution \texttt{COMMON(3, 4, \langle 7, 9, 7, 5 \rangle, \langle 9, 7, 9, 9, 6, 9 \rangle)}.

The five parameters of \texttt{vals([VARIABLES1.var, VARIABLES2.var], int, \neq, all, dontcare)} have the following meaning:

- \texttt{[VARIABLES1.var, VARIABLES2.var]} indicates that the modification takes place within the values assigned to the \texttt{var} attribute of the \texttt{VARIABLES1} and \texttt{VARIABLES2} collections.
- \texttt{int} defines the partition of values $\mathcal{P} = \ldots, \{−1\}, \{0\}, \{1\}, \ldots$.
- \texttt{\neq} indicates that the exchange of values takes place between two distinct elements of $\mathcal{P}$.
- \texttt{all} specifies that all occurrences of the source value have to be exchanged with all occurrences of the target value.
- \texttt{dontcare} tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in \texttt{VARIABLES1} or \texttt{VARIABLES2}.

We now present an example that illustrates the fact that value symmetry can also occur between two arguments that both correspond to a domain variable, i.e., not just between the variables of a collection of variables. For this purpose we consider the \texttt{LEQ} constraint.
EXAMPLE 9: Consider the \texttt{LEQ}(\texttt{VAR1}, \texttt{VAR2}) constraint, which forces \texttt{VAR1} to be less than or equal to \texttt{VAR2}. Note that \texttt{VAR1} can be decreased to any value, and that \texttt{VAR1} can be increased up to \texttt{VAR2}. Similarly, \texttt{VAR2} can be increased to any value, and \texttt{VAR2} can be decreased down to \texttt{VAR1}. Within the electronic catalogue this is respectively represented by the following meta-data, \texttt{vals}([\texttt{VAR1}], \texttt{int}(\leq (\texttt{VAR2})), \neq, \texttt{all}, \texttt{dontcare}) and \texttt{vals}([\texttt{VAR2}], \texttt{int}(\geq (\texttt{VAR1})), \neq, \texttt{all}, \texttt{dontcare}), to which corresponds the following textual form:

\begin{itemize}
  \item \texttt{VAR1} can be replaced by any value \leq \texttt{VAR2};
  \item \texttt{VAR2} can be replaced by any value \geq \texttt{VAR1}.
\end{itemize}

For example, since \texttt{LEQ(2, 9)} is a solution, we can replace value 2 by any value less than or equal to 9, e.g. value 5 and get another valid solution \texttt{LEQ(5, 9)}. But, within \texttt{LEQ(2, 9)}, we can also replace value 9 with any other value greater than or equal to 2, e.g. value 4 and get another valid solution \texttt{LEQ(2, 4)}.

The five parameters of \texttt{vals}([\texttt{VAR1}], \texttt{int}(\leq (\texttt{VAR2})), \neq, \texttt{all}, \texttt{dontcare}) have the following meaning:

\begin{itemize}
  \item \texttt{[VAR1]} indicates that the modification takes place within the value assigned to the argument \texttt{VAR1} of the constraint \texttt{LEQ}.
  \item \texttt{int}(\leq (\texttt{VAR2})) defines the partition of values \mathcal{P} = \ldots, \{\texttt{VAR2} - 2\}, \{\texttt{VAR2} - 1\}, \{\texttt{VAR2}\} (i.e., we only consider values that are less than or equal to \texttt{VAR2}).
  \item \texttt{\neq} indicates that the exchange of values takes place between two distinct elements of \mathcal{P}.
  \item \texttt{all} specifies that all occurrences of the source value have to be replaced by the target value. Note that, since the scope of the change is reduced to a single variable, we have one occurrence of the source value and no occurrence of the target value.
  \item \texttt{dontcare} tells that the source value will be replaced by a new value.
\end{itemize}

The meta-data \texttt{vals}([\texttt{VAR2}], \texttt{int}(\geq (\texttt{VAR1})), \neq, \texttt{all}, \texttt{dontcare}) has a similar explanation.

We now present two examples related to the \texttt{K_DISJOINT} constraint. The first example illustrates the fact the path specifying the scope of the exchange can contain more than one collection. The second example exemplifies the fact the path specifying the scope of the exchange does not necessarily start with a top level collection.
EXAMPLE 10: Consider the $\text{K\_DISJOINT}(\text{SETS})$ constraint which, given $|\text{SETS}|$ sets of domain variables, forces that no value is assigned to more than one set. Note that we can swap all the occurrences of two values, or replace all occurrences of a value by a value that is not yet used. Within the electronic catalogue this is represented by the following meta-data, $\text{vals}([\text{SETS}.\text{set}.\text{var}], \text{int}, \neq, \text{all}, \text{dontcare})$, to which corresponds the following textual form:

*All occurrences of two distinct values of $\text{SETS}.\text{set}.\text{var}$ can be swapped; all occurrences of a value of $\text{SETS}.\text{set}.\text{var}$ can be renamed to any unused value.*

For example, since $\text{K\_DISJOINT}((\text{set} — \langle 1, 9, 1, 5 \rangle, \text{set} — \langle 7, 2, 7 \rangle))$ is a solution, we can replace value 1 by any value that is different from the already used values 2, 5, 7, and 9, e.g. value 3, and get another valid solution $\text{K\_DISJOINT}((\text{set} — \langle 3, 9, 3, 5 \rangle, \text{set} — \langle 7, 2, 7 \rangle))$. From the solution $\text{K\_DISJOINT}((\text{set} — \langle 1, 9, 1, 5 \rangle, \text{set} — \langle 7, 2, 7 \rangle))$, we can also swap all occurrences of two values, e.g. values 1 and 2, and get another valid solution $\text{K\_DISJOINT}((\text{set} — \langle 2, 9, 2, 5 \rangle, \text{set} — \langle 7, 1, 7 \rangle))$.

The five parameters of $\text{vals}([\text{SETS}.\text{set}.\text{var}], \text{int}, \neq, \text{all}, \text{dontcare})$ have the following meaning:

- $[\text{SETS}.\text{set}.\text{var}]$ indicates that the modification takes place within the values assigned to the var attribute of the $\text{SETS}.\text{set}$ collections.
- int defines the partition of values $\mathcal{P} = \ldots, \{-1\}, \{0\}, \{1\}, \ldots$
- $\neq$ indicates that the exchange of values takes place between two distinct elements of $\mathcal{P}$.
- all specifies that all occurrences of the source value have to be exchanged with all occurrences of the target value.
- dontcare tells that the source value can be replaced by an already existing value or by a new value, i.e., a value not already used in $\text{SETS}.\text{set}.\text{var}$. 
EXAMPLE 11: Consider the $\text{K\_DISJOINT(SETS)}$ constraint which, given $|\text{SETS}|$ sets of domain variables, forces that no value is assigned to more than one set. Note that, within any set, we can replace any occurrence of a value by another value that is already used in the same set. Within the electronic catalogue this is represented by the following meta-data, \texttt{vals([\text{VARIABLES.var}], \text{int}, \neq, \text{dontcare}, \text{in})}, to which corresponds the following textual form:

An occurrence of a value of \text{VARIABLES.var} can be replaced by any value of \text{VARIABLES.var}.

For example, since $\text{K\_DISJOINT}((\text{set} \rightarrow \langle 1, 9, 1, 5 \rangle, \text{set} \rightarrow \langle 7, 2, 7 \rangle))$ is a solution, we can replace within the first set the first occurrence of value $1$ by the already used value $5$, and get another valid solution $\text{K\_DISJOINT}((\text{set} \rightarrow \langle 5, 9, 1, 5 \rangle, \text{set} \rightarrow \langle 7, 2, 7 \rangle))$. The five parameters of \texttt{vals([\text{VARIABLES.var}], \text{int}, \neq, \text{dontcare}, \text{in})} have the following meaning:

- [\text{VARIABLES.var}] indicates that the modification takes place within the values assigned to the \text{var} attribute of the \text{VARIABLES.var} collections. Note that since the corresponding path does not start from a top level collection (i.e., \text{VARIABLES} does not correspond to an argument of the \text{K\_DISJOINT} constraint), this represents one set of values for each set: the scope of value symmetry is located within a single set.
- \text{int} defines the partition of values $P = \ldots, \{-1\}, \{0\}, \{1\}, \ldots$
- $\neq$ indicates that the exchange of values takes place between two distinct elements of $P$.
- \text{dontcare} specifies that one occurrence of the source value has to be replaced by the target value.
- \text{in} tells that the source value has to be replaced by an already existing value in \text{VARIABLES.var}.

We present a last example where the path specifying the scope of the exchange does not end with an attribute but rather with a collection. This can be seen as a generalisation of value symmetry where, instead of exchanging values, we exchange tuples of values. This kind of value symmetry occurs in constraints like $\text{COND\_LEX\_COST}$, $\text{IN\_RELATION}$, $\text{NPAIR}$, $\text{NVECTOR}$, $\text{NVECTORS}$, or $\text{PATTERN}$. 
EXAMPLE 12: Consider the `NVECTOR(NVEC, VECTORS)` constraint which forces an equality between `NVEC` and the number of distinct tuples of values taken by the vectors of the collection `VECTORS`. Note that we can swap all the occurrences of two tuples of values, or replace all occurrences of a tuple of values by a tuple of values that is not yet used. Within the electronic catalogue this is represented by the following meta-data, `vals([VECTORS.vec], int, ≠, all, dontcare)`, to which corresponds the following textual form:

All occurrences of two distinct tuples of values of `VECTORS.vec` can be swapped; all occurrences of a tuple of values of `VECTORS.vec` can be renamed to any unused tuple of values.

For example, since `NVECTOR(2, ⟨vec − ⟨5, 6⟩, vec − ⟨9, 2⟩, vec − ⟨5, 6⟩⟩)` is a solution, we can replace all the occurrences of the tuple of values ⟨5, 6⟩ by any unused tuple of values, e.g. the tuple of values ⟨1, 2⟩, and get another valid solution `NVECTOR(2, ⟨vec − ⟨1, 2⟩, vec − ⟨9, 2⟩, vec − ⟨1, 2⟩⟩)`.

The five parameters of `vals([VECTORS.vec], int, ≠, all, dontcare)` have the following meaning:

- `[VECTORS.vec]` indicates that the modification takes place within the tuples of values assigned to the `vec` attribute of the `VECTORS` collections.
- `int` defines the partition of values \( P = \mathbb{Z}^{[VECTORS]} \).
- `≠` indicates that the exchange of tuple of values takes place between two distinct elements of \( P \).
- `all` specifies that all occurrences of the source tuple of values have to be exchanged with all occurrences of the target tuple of values.
- `dontcare` tells that the source tuple of values can be replaced by an already existing tuple of values or by a new tuple of values, i.e., a tuple of values not already used in `VECTORS.vec`.

- `translate(ATTRIBUTES)` denotes the fact that we add a constant to some collection attributes (i.e., we express the fact that solutions are preserved under some specific translation). `ATTRIBUTES` is a list of terms of the form `ARG1`, or `ARG2.attr`, or `ARG3.attr\(_i\).attr\(_j\)`, where:

  - `ARG1` is an argument of the global constraint of type domain variable or integer.
  - `ARG2` is an argument of the global constraint that corresponds to a collection, and `attr` is an attribute of `ARG2` of type domain variable or integer.
  - `ARG3` is an argument of the global constraint that corresponds to a collection, and `attr\(_i\)` is an attribute of `ARG3` of type collection, and `attr\(_j\)` is an attribute of `ARG3.attr\(_i\)` of type domain variable or integer.

Its purpose is to define all the elements that have to be simultaneously incremented by one and the same constant.

- The case corresponding to `ARG1` is motivated by the fact that we sometimes want to increment an argument that is a domain variable or an integer.
2.2. DESCRIBING THE ARGUMENTS OF A GLOBAL CONSTRAINT

- The case corresponding to ARG2.attr is the standard case where we want to express that we increment attribute attr of all items of a collection that is passed as an argument of the global constraint.

- Finally, the last case ARG3.attr_i.attr_j corresponds to the fact that we want to increment attribute attr_j of all items corresponding to ARG3.attr_i.

We now provide two examples, where the translation is respectively applied on a single attribute and on two attributes of a collection.

**EXAMPLE 1:** Consider the \texttt{ALL\_MIN\_DIST}(MINDIST, VARIABLES) constraint which forces for each pair \((\text{var}_i, \text{var}_j)\) of distinct variables of the collection VARIABLES that \(|\text{var}_i - \text{var}_j| \geq \text{MINDIST}\). Note that we can add one and the same constant to all variables of the collection VARIABLES since this does not change the difference between any pair of variables. Within the electronic catalogue this is represented by the following meta-data, \texttt{translate([VARIABLES.var])}, to which corresponds the following textual form:

\begin{itemize}
  \item One and the same constant can be added to the \text{var} attribute of all items of VARIABLES.
\end{itemize}

For example, since \texttt{ALL\_MIN\_DIST}(2, \langle 5, 1, 9, 3 \rangle) is a solution, we can add the constant 6 to all items of the collection \langle 5, 1, 9, 3 \rangle, and get another valid solution \texttt{ALL\_MIN\_DIST}(2, \langle 11, 7, 15, 9 \rangle).

**EXAMPLE 2:** Consider the \texttt{CUMULATIVE}(TASKS, LIMIT) constraint which forces that at each point in time, the cumulated height of the set of tasks that overlap that point, does not exceed a given limit. Note that we can add one and the same constant to all origin and end attributes of the different tasks of the TASKS collection. This operation simply shifts the overall schedule by a given constant without affecting the maximum resource consumption. Within the electronic catalogue this is represented by the following meta-data, \texttt{translate([TASKS.origin, TASKS.end])}, to which corresponds the following textual form:

\begin{itemize}
  \item One and the same constant can be added to the \text{origin} and \text{end} attributes of all items of TASKS.
\end{itemize}

For example, since

\[
\begin{pmatrix}
\text{origin} - 1 & \text{duration} - 3 & \text{end} - 4 & \text{height} - 1, \\
\text{origin} - 2 & \text{duration} - 9 & \text{end} - 11 & \text{height} - 2, \\
\text{origin} - 3 & \text{duration} - 10 & \text{end} - 13 & \text{height} - 1, \\
\text{origin} - 6 & \text{duration} - 6 & \text{end} - 12 & \text{height} - 1, \\
\text{origin} - 7 & \text{duration} - 2 & \text{end} - 9 & \text{height} - 3
\end{pmatrix}, 8
\]

is a solution, we can add the constant 2 to all origin and end attributes, and get another valid solution

\[
\begin{pmatrix}
\text{origin} - 3 & \text{duration} - 3 & \text{end} - 6 & \text{height} - 1, \\
\text{origin} - 4 & \text{duration} - 9 & \text{end} - 13 & \text{height} - 2, \\
\text{origin} - 5 & \text{duration} - 10 & \text{end} - 15 & \text{height} - 1, \\
\text{origin} - 8 & \text{duration} - 6 & \text{end} - 14 & \text{height} - 1, \\
\text{origin} - 9 & \text{duration} - 2 & \text{end} - 11 & \text{height} - 3
\end{pmatrix}, 8
\].
We conclude by listing other types of symmetries that we may also consider in the future, namely:

- In the context of graph constraints we can usually relabel the vertices of the corresponding graph. This is the case, for example, of the CIRCUIT constraint where the index attribute corresponds to the name of a vertex.

- In the context of constraints on a matrix we can have symmetries on both the rows and the columns of the matrix. On the one hand, since a row corresponds to a collection this can be currently expressed. On the other hand, since a column corresponds to all the \( i \)th items of the collections corresponding to the rows, this currently cannot be expressed.

- Given a collection of items, we want to express a symmetry on different subsets of items: more precisely, on all items for which a given attribute is assigned the same value. As an illustrative example consider the CUMULATIVES constraint. We would like to express the possibility of translating the origin of all tasks that are assigned the same machine.

- Given a collection of items we can sometimes multiply by \(-1\) all occurrences of one of its attributes. This usually corresponds to a mirror symmetry. This is the case, for example, for the origin attribute of the CUMULATIVE constraint.

2.3 Describing global constraints in terms of graph properties

Through a practical example, we first present in a simplified form the basic principles used for describing the meaning of global constraints in terms of graph properties. We then give the full details about the different features used in the description process.

2.3.1 Basic ideas and illustrative example

Within the graph-based representation, a global constraint is represented as a digraph where each vertex corresponds to a variable and each arc to a binary arc constraint between the variables associated with the extremities of the corresponding arc. The main difference from classical constraint networks [142], stems from the fact that we do not force any more all arc constraints to hold. We rather consider this graph from which we discard all the arc constraints that do not hold as well as all isolated vertices (i.e, vertices not involved any more in any arc) and impose one or several graph properties on this remaining graph. These properties can be, for example, a restriction on the number of connected components, on the size of the smallest connected component or on the size of the largest connected component.
2.3. **Describing global constraints in terms of graph properties**

![Graph Properties Diagram](image)

**Figure 2.5**: Illustration of the link between graph properties and global constraints

**Example**: We give an example of interpretation of such graph properties in terms of global constraints. For this purpose we consider the sequence $s$ of values 1 3 1 2 8 8 2 3 6 8 8 3 from which we construct the following graph $G$:

- To each value associated with a position in $s$ corresponds a vertex of $G$.
- There is an arc from a vertex $v_1$ to a vertex $v_2$ if these vertices correspond to the same value.

Figure 2.5 depicts graph $G$. Since $G$ is symmetric, we omit the directions of the arcs.

We have the following correspondence between graph properties and constraints on the sequence $s$:

- The number of connected components of $G$ corresponds to the number of distinct values of $s$.
- The size of the smallest connected component of $G$ is the smallest number of occurrences of the same value in $s$.
- The size of the largest connected component of $G$ is the largest number of occurrences of the same value in $s$.

As a result, in this context, putting a restriction on the number of connected components of $G$ can be seen as a global constraint on the number of distinct values of a sequence of variables. Similar global constraints can be associated with the two other graph properties.

We now explain how to generate the initial graph associated with a global constraint. A global constraint has one or more arguments, which usually correspond to an integer value, to one variable or to a collection of variables. Therefore we have to describe the process that allows for generating the vertices and the arcs of the initial graph from the arguments of a global constraint under consideration. For this purpose we will take a concrete example.

Consider the constraint $NVALUE(NVAL, VARIABLES)$ where $NVAL$ and $VARIABLES$ respectively correspond to a domain variable and to a collection of domain variables
2. DESCRIBING GLOBAL CONSTRAINTS

\( \langle \text{var} - V_1, \text{var} - V_2, \ldots, \text{var} - V_m \rangle \). This constraint holds if NVAL is equal to the number of distinct values assigned to the variables \( V_1, V_2, \ldots, V_m \). We first show how to generate the initial graph associated with the NVALUE constraint. We then describe the arc constraint associated with each arc of this graph. Finally, we give the graph property we impose on the final graph.

To each variable of the collection VARIABLES corresponds a vertex of the initial graph. We generate an arc between each pair of vertices. To each arc, we associate an equality constraint between the variables corresponding to the extremities of that arc. We impose that NVAL, the variable corresponding to the first argument of NVALUE, be equal to the number of strongly connected components of the final graph. This final graph consists of the initial graph from which we discard all arcs such that the corresponding equality constraint does not hold.

Part (A) of Figure 2.6 shows the graph initially generated for the constraint NVALUE (NVAL, \( \langle \text{var} - V_1, \text{var} - V_2, \text{var} - V_3, \text{var} - V_4 \rangle \)), where NVAL, V_1, V_2, V_3 and V_4 are domain variables. Part (B) presents the final graph associated with the ground instance NVALUE(3, \( \langle \text{var} - 5, \text{var} - 5, \text{var} - 1, \text{var} - 8 \rangle \)). For each vertex of the initial and final graph we respectively indicate the corresponding variable and the value assigned to that variable. We have removed from the final graph all the arcs associated with equalities that do not hold. The constraint NVALUE(3, \( \langle \text{var} - 5, \text{var} - 5, \text{var} - 1, \text{var} - 8 \rangle \)) holds since the final graph contains three strongly connected components, which in the context of the definition of the NVALUE constraint, can be reinterpreted as the fact that NVAL is the number of distinct values assigned to variables \( V_1, V_2, V_3, V_4 \).

Figure 2.6: (A) Initial and (B) final graph associated with the constraint NVALUE(3, \( \langle \text{var} - 5, \text{var} - 5, \text{var} - 1, \text{var} - 8 \rangle \))

Now that we have illustrated the basic ideas for describing a global constraint in terms of graph properties, we go into more details.

### 2.3.2 Ingredients used for describing global constraints

We first introduce the basic ingredients used for describing a global constraint and illustrate them shortly on the example of the NVALUE constraint introduced in the previous

\[^{12}\text{var} \text{ corresponds to the name of the attribute used in the collection of variables.}\]
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

section on page 49. We then go through each basic ingredient in more detail. The graph-based description is founded on the following basic ingredients:

- **Data types and restrictions** used in order to describe the arguments of a global constraint. Data types and restrictions were already described in the previous section (from page 14 to page 27).

- **Collection generators** used in order to derive new collections from the arguments of a global constraint for one of the following reasons:
  
  - Collection generators are sometimes required since the initial graph of a global constraint cannot always be directly generated from the arguments of the global constraint. The \( \text{NVALUE}(\text{NVAL}, \text{VARIABLES}) \) constraint did not require any collection generator since the vertices of its initial graph were directly generated from the \text{VARIABLES} collection.
  
  - A second use of collection generators is for deriving a collection of items for different set of vertices of the final graph. This is sometimes required when we use set generators (see the last item of the enumeration).

- **Elementary constraints** associated with the arcs of the initial and final graph of a global constraint. The \( \text{NVALUE} \) constraint was using an equality constraint, but other constraints are usually required.

- **Graph generators** employed for constructing the initial graph of a global constraint. In the context of the \( \text{NVALUE} \) constraint the initial graph was a clique. As we will see later, other patterns are needed for generating an initial graph.

- **Graph properties** and graph classes used for constraining the final graph we want to obtain. In the context of the \( \text{NVALUE} \) constraint we were using the number of strongly connected components for counting the number of distinct values.

- **Set generators** that may be used for generating specific sets of vertices of the final graph on which we want to enforce a given constraint. Since the \( \text{NVALUE} \) constraint forces a graph property on the final graph (and not on subparts of the final graph) we did not use this feature.

We first start to explain each ingredient separately and then show how one can describe most global constraints in terms of these basic ingredients.

**Collection generators**

The vertices of the initial graph are usually directly generated from collections of items that are arguments of the global constraint \( G \) under consideration. However, it sometimes happens that we would like to derive a new collection from existing arguments of \( G \) in order to produce the vertices of the initial graph.
2. DESCRIBING GLOBAL CONSTRAINTS

EXAMPLE: This is the case, for example, of the `ELEMENT(INDEX, TABLE, VALUE)` constraint, where `INDEX` and `VALUE` are domain variables that we would like to group as a single item $I$ (with two attributes) of a new derived collection. This is in fact done in order to generate the following initial graph:

- The item $I$ as well as all items of `TABLE` constitute the vertices,
- There is an arc from $I$ to each item of the `TABLE` collection.

We provide the following mechanism for deriving new collections:

- In a first phase we declare the name of the new collection as well as the names of its attributes and their respective types. This is achieved exactly in the same way as those collections that are used in the arguments of a global constraint (see page 16).

EXAMPLE: Consider again the example of the `ELEMENT(INDEX, TABLE, VALUE)` constraint. The declaration `ITEM − collection(index − dvar, value − dvar)` introduces a new collection called `ITEM` where each item has an `index` and a `value` attribute. Both attributes correspond to domain variables.

- In a second phase we give a list of patterns that are used for generating the items of the new collection. A pattern $o − item(a_1 − v_1, a_2 − v_2, ..., a_n − v_n)$ or $item(a_1 − v_1, a_2 − v_2, ..., a_n − v_n)$ specifies for each attribute $a_i (1 \leq i \leq n)$ of the new collection how to fill it.\(^\text{13}\) This is done by providing for each attribute $a_i$ one of the following expression $v_i$:

- A constant.
- An argument of the global constraint $G$.
- An expression $c.a$, where $a$ is an attribute of a collection $c$, such that $c$ is an argument of the global constraint $G$ or a derived collection that was previously declared. An expression of this form is called a direct reference to an attribute of a collection.
- An expression $c_1.c_2.a$, where $a$ is an attribute of a collection $c_2$, and $c_2$ is an attribute of a collection $c_1$ such that $c_1$ is an argument of the global constraint $G$ or a derived collection that was previously declared. An expression of this form is called an indirect reference to an attribute of a collection.

This expression $v_i$ must be compatible with the type declaration of the corresponding attribute of the new collection.

\(^{13}\) $o$ is one of the comparison operators $=, \neq, <, \geq, >, \leq$. When omitted its default value is $=$.
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

**EXAMPLE:** We continue the example of the `ELEMENT(INDEX, TABLE, VALUE)` constraint and the derived collection `ITEM - COLLEcTION(index - dvar, value - dvar)`. The pattern `item(index - INDEX, value - VALUE)` indicates that:

- The index attribute of the `ITEM` collection will be generated by using the `INDEX` argument of the `ELEMENT` constraint. Since `INDEX` is a domain variable, it is compatible with the declaration `ITEM - COLLEcTION(index - dvar, value - dvar)` of the new collection.
- The value attribute of the `ITEM` collection will be generated by using the `VALUE` argument of the `ELEMENT` constraint. `VALUE` is also compatible with the declaration statement of the new collection.

We now describe how we use the pattern for generating the items of a derived collection. We have the following two cases:

- If the pattern `o - item(a₁ - v₁, a₂ - v₂, ..., aₙ - vₙ)` does not contain any direct or indirect reference to an attribute of a collection then we generate a single item for such pattern. In this context the value `vᵢ` of the attribute `aᵢ` (1 ≤ i ≤ n) corresponds to a constant, to an argument of the global constraint or to a new derived collection.
- If the pattern `o - item(a₁ - v₁, a₂ - v₂, ..., aₙ - vₙ)`, where `o` is one of the comparison operators `=, ≠, <, >, ≥, ≤`, contains one or several direct or indirect references to an attribute of a collection we denote by:

- `D` the set of indices of the positions corresponding to a direct reference to an attribute of a collection within `item(a₁ - v₁, a₂ - v₂, ..., aₙ - vₙ)`. In this context, let `cᵩ₁, cᵩ₂, ..., cᵩₘ` and `aᵩ₁, aᵩ₂, ..., aᵩₘ` respectively denote the corresponding collections and attributes.
- `I` the set of indices of the positions corresponding to an indirect reference to an attribute of a collection within `item(a₁ - v₁, a₂ - v₂, ..., aₙ - vₙ)`. In this context, let `cᵦ₁, cᵦ₂, ..., cᵦᵣ, cᵦₙ, cᵦ₁, cᵦ₂, ..., cᵦₙ` and `aᵦ₁, aᵦ₂, ..., aᵦₙ` respectively denote the corresponding collections, attributes of type collection and attributes.
- Let `dir₁, dir₂, ..., dirₘ`, `ind₁, ind₂, ..., indₚ` and `id₁, id₂, ..., idₘ₊ₚ` respectively denote the indices sorted in increasing order of `D`, `I` and `D∪I`.

For each combination of items `cᵩ₁[j₁], cᵩ₂[j₂], ..., cᵩₘ[iₘ], cᵦ₁[k₁], cᵦ₂[k₂], ..., cᵦₙ[ᵦₙ]` such that:

\[
\begin{align*}
    i₁ &\in [1, |cᵩ₁|], & i₂ &\in [1, |cᵩ₂|], & \ldots & & iₘ &\in [1, |cᵩₘ|] \\
    j₁ &\in [1, |cᵦ₁|], & j₂ &\in [1, |cᵦ₂|], & \ldots & & jₚ &\in [1, |cᵦₚ|] \\
    k₁ &\in [1, |cᵦ₁[j₁]|], & k₂ &\in [1, |cᵦ₂[j₂]|], & \ldots & & kₚ &\in [1, |cᵦₙ[ᵦₙ]|] \\
    id₁ &\circ id₂ &\circ \ldots & idₘ₊ₚ
\end{align*}
\]

we generate an item of the new derived collection `(a₁ - w₁ a₂ - w₂ \ldots aₙ - wₙ)` defined by:

---

14 In this first case the value of `o` is irrelevant.
15 This collection is an argument of the global constraint or corresponds to a newly derived collection.
2. DESCRIBING GLOBAL CONSTRAINTS

\[ w_j (1 \leq j \leq n) = \begin{cases} 
  c_{\alpha_r}[i_r]a_{\alpha_r} & \text{if } j \in D, j = dir_r \\
  c_{\beta_r}[i_r]c_{\beta_r}[k_r]a_{\beta_r} & \text{if } j \in I, j = ind_r \\
  v_j & \text{if } j \notin D \cup I 
\end{cases} \]

We illustrate this generation process on a set of examples. Each example is described by providing:

- The global constraint and its arguments,
- The declaration of the new derived collection,
- The pattern used for creating an item of the new collection,
- The items generated by applying this pattern to the global constraint,
- A comment about the generation process.

We first start with four examples that do not mention any references to an attribute of a collection. A box surrounds an argument of a global constraint that is mentioned in a generated item.

**EXAMPLE**

**CONSTRAINT**: `ELEMENT(INDEX, TABLE, VALUE)`
**DERIVED COLLECTION**: `ITEM−collection(index−dvar, value−dvar)`
**PATTERN(S)**: `item(index−INDEX, value−VALUE)`
**GENERATED ITEM(S)**: `⟨index−INDEX value−VALUE⟩`

We generate a single item where the two attributes index and value respectively take the first argument INDEX and the third argument VALUE of the `ELEMENT` constraint.

**EXAMPLE**

**CONSTRAINT**: `LEX_LESSEQ(VECTOR1, VECTOR2)`
**DERIVED COLLECTION**: `DESTINATION−collection(index−int, x−int, y−int)`
**PATTERN(S)**: `item(index−0, x−0, y−0)`
**GENERATED ITEM(S)**: `⟨index−0 x−0 y−0⟩`

We generate a single item where the three attributes index, x and y take value 0.

**EXAMPLE**

**CONSTRAINT**: `IN_RELATION(VARIABLES, TUPLES_OF_VALS)`
**DERIVED COLLECTION**: `TUPLES_OF_VARS−collection(vec−TUPLE_OF_VARS)`
**PATTERN(S)**: `item(vec−VARIABLES)`
**GENERATED ITEM(S)**: `⟨vec−VARIABLES⟩`

We generate a single item where the unique attribute vec takes the first argument of the `IN_RELATION` constraint as its value.
2.3. Describing Global Constraints in Terms of Graph Properties

**Example**

**Constraint:** \( \text{DOMAIN\_CONSTRAINT}([\text{VAR}], \text{VALUES}) \)

**Derived Collection:** \( \text{VALUE} \rightarrow \text{collection}(\text{var01} \rightarrow \text{int}, \text{value} \rightarrow \text{dvar}) \)

**Pattern(s):** \( \text{item}(\text{var01} \rightarrow 1, \text{value} \rightarrow \text{VAR}) \)

**Generated Item(s):** \( (\text{var01} \rightarrow 1, \text{value} \rightarrow \text{VAR}) \)

We generate a single item where the two attributes \( \text{var01} \) and \( \text{value} \) respectively take value 1 and the first argument of the \( \text{DOMAIN\_CONSTRAINT} \) constraint.

We continue with three examples that mention one or several direct references to an attribute of some collections. We now need to explicitly give the items of these collections in order to generate the items of the derived collection.

**Example**

**Constraint:** \( \text{LEX\_LESSEQ}(\text{VECTOR1}, \text{VECTOR2}) \)

**VECTOR1:** \( (\text{var} \rightarrow 5, \text{var} \rightarrow 2, \text{var} \rightarrow 3, \text{var} \rightarrow 1) \)

**VECTOR2:** \( (\text{var} \rightarrow 5, \text{var} \rightarrow 2, \text{var} \rightarrow 6, \text{var} \rightarrow 2) \)

**Derived Collection:** \( \text{COMPONENTS} \rightarrow \text{collection}(\text{index} \rightarrow \text{int}, \text{x} \rightarrow \text{dvar}, \text{y} \rightarrow \text{dvar}) \)

**Pattern(s):** \( \text{item}(\text{index} \rightarrow \text{VECTOR1}.\text{key}, \text{x} \rightarrow \text{VECTOR1}.\text{var}, \text{y} \rightarrow \text{VECTOR2}.\text{var}) \)

**Generated Item(s):** \( (\text{index} \rightarrow 1, \text{x} \rightarrow 5, \text{y} \rightarrow 5), (\text{index} \rightarrow 2, \text{x} \rightarrow 2, \text{y} \rightarrow 2), (\text{index} \rightarrow 3, \text{x} \rightarrow 6, \text{y} \rightarrow 2), (\text{index} \rightarrow 4, \text{x} \rightarrow 1, \text{y} \rightarrow 2) \)

The pattern mentions three references \( \text{VECTOR1}.\text{key}, \text{VECTOR1}.\text{var} \) and \( \text{VECTOR2}.\text{var} \) to the collections \( \text{VECTOR1} \) and \( \text{VECTOR2} \) used in the arguments of the \( \text{LEX\_LESSEQ} \) constraint. \( \forall i_1 \in [1, |\text{VECTOR1}|], \forall i_2 \in [1, |\text{VECTOR2}|] \) such that \( i_1 = i_2 \), we generate an item \( \text{index} \rightarrow v_1, \text{x} \rightarrow v_2, \text{y} \rightarrow v_3 \) where:

\( v_1 = i_1, \quad v_2 = \text{VECTOR1}[i_1].\text{var}, \quad v_3 = \text{VECTOR2}[i_1].\text{var} \).

This leads to the four items listed in the \( \text{GENERATED ITEM(S)} \) field.

---

\(^a\)As defined in Section 2.2.2 on page 16, \( \text{key} \) is an implicit attribute corresponding to the position of an item within a collection.

\(^b\)We use an equality since this is the default value of the comparison operator \( o \) when we do not use a pattern of the form \( o - \text{item}(...) \).
2. DESCRIBING GLOBAL CONSTRAINTS

EXAMPLE

CONSTRAINT : $\text{CUMULATIVES}([\text{TASKS}\text{ MACHINES,CTR}])$

TASKS : $(\text{machine} - 1 \text{ origin} - 1 \text{ duration} - 4 \text{ end} - 5 \text{ height} - 1, \text{machine} - 1 \text{ origin} - 4 \text{ duration} - 2 \text{ end} - 6 \text{ height} - 3, \text{machine} - 1 \text{ origin} - 2 \text{ duration} - 3 \text{ end} - 5 \text{ height} - 2, \text{machine} - 2 \text{ origin} - 5 \text{ duration} - 2 \text{ end} - 7 \text{ height} - 2)$

DERIVED COLLECTION: $\text{TIME_POINTS} - \text{collection}(\text{idm} - \text{int},$
$\text{duration} - \text{dvar}, \text{point} - \text{dvar})$

PATTERN(S) : $\text{item}(\text{idm} - \text{TASKS.machine},$
$\text{duration} - \text{TASKS.duration}, \text{point} - \text{TASKS.origin})$
$\text{item}(\text{idm} - \text{TASKS.machine},$
$\text{duration} - \text{TASKS.duration}, \text{point} - \text{TASKS.end})$

GENERATED ITEM(S) : $(\text{idm} - 1 \text{ duration} - 4 \text{ point} - 1, \text{idm} - 1 \text{ duration} - 2 \text{ point} - 4, \text{idm} - 1 \text{ duration} - 3 \text{ point} - 2, \text{idm} - 2 \text{ duration} - 2 \text{ point} - 5, \text{idm} - 1 \text{ duration} - 4 \text{ point} - 5, \text{idm} - 1 \text{ duration} - 2 \text{ point} - 6, \text{idm} - 1 \text{ duration} - 3 \text{ point} - 5, \text{idm} - 2 \text{ duration} - 2 \text{ point} - 7)$

The two patterns mention the references $\text{TASKS.machine, TASKS.duration, TASKS.origin}$ and $\text{TASKS.end}$ of the TASKS collection used in the arguments of the $\text{CUMULATIVES}$ constraint. $\forall i \in [1,|\text{TASKS}|]$, we generate two items $\text{idm} - u_1 \text{ duration} - u_2 \text{ point} - u_3, \text{idm} - v_1 \text{ duration} - v_2 \text{ point} - v_3$ where:
$u_1 = \text{TASKS}[i].\text{machine}, u_2 = \text{TASKS}[i].\text{duration}, u_3 = \text{TASKS}[i].\text{origin}, v_1 = \text{TASKS}[i].\text{machine}, v_2 = \text{TASKS}[i].\text{duration}, v_3 = \text{TASKS}[i].\text{end}$. This leads to the eight items listed in the GENERATED ITEM(S) field.

EXAMPLE

CONSTRAINT : $\text{GOLOMB}([\text{VARIABLES}])$

VARIABLES : $(\text{var} - 0, \text{var} - 1, \text{var} - 4, \text{var} - 6)$

DERIVED COLLECTION: $\text{PAIRS} - \text{collection}(x - \text{dvar}, y - \text{dvar})$

PATTERN(S) : $> - \text{item}(x - \text{VARIABLES.var}, y - \text{VARIABLES.var})$

GENERATED ITEM(S) : $(x - 1 y - 0, x - 4 y - 0, x - 4 y - 1, x - 6 y - 0, x - 6 y - 1, x - 6 y - 4)$

The pattern mentions two references $\text{VARIABLES.var}$ and $\text{VARIABLES.var}$ to the VARIABLES collection used in the arguments of the $\text{GOLOMB}$ constraint. $\forall i_1 \in [1,|\text{VARIABLES}|], \forall i_2 \in [1,|\text{VARIABLES}|]$ such that $i_1 > i_2$ we generate the item $x - u_1 y - u_2$ where:
$u_1 = \text{VARIABLES}[i_1].\text{var}, u_2 = \text{VARIABLES}[i_2].\text{var}$. This leads to the six items listed in the GENERATED ITEM(S) field.

*We use the comparison operator $>$ since we have a pattern of the form $> - \text{item}(\ldots)$.*
2.3. DESCRIPTING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

We finish with an example that mentions an indirect reference to an attribute of a collection.

**EXAMPLE**

**CONSTRAINT** : `CUMULATIVE_CONVEX(TASKS, LIMIT)`

**TASKS** :
- `(points − (var − 2, var − 1, var − 5)) height − 1`,
- `(points − (var − 4, var − 5, var − 7)) height − 2`,
- `(points − (var − 14, var − 15)) height − 2`

**DERIVED COLLECTION** : `INSTANTS − collection(instant − int)`

**PATTERN** (S) :
- `item(instant − TASKS.points.var)`

**GENERATED ITEM** (S) :
- `(instant − 2, instant − 1, instant − 5, instant − 4, instant − 5, instant − 7, instant − 14, instant − 15)`

The pattern mentions the indirect reference `TASKS.points.var` of the `TASKS` collection used in the arguments of the `CUMULATIVE_CONVEX` constraint. ∀i ∈ [1, |TASKS|], ∀j ∈ [1, |TASKS[i].points|] we generate the item `instant − u_{ij}` where:

\[ u_{ij} = TASKS[i].points[j] \]

This leads to the eight items listed in the **GENERATED ITEM** (S) field.

**Elementary constraints attached to the arcs**

This section describes the constraints that are associated with the arcs of the initial graph of a global constraint. These constraints are called arc constraints. To each arc one can associate one or several arc constraints. An arc will belong to the final graph if and only if all its arc constraints hold. An arc constraint from a vertex \( v_1 \) to a vertex \( v_2 \) mentions variables and/or values associated with \( v_1 \) and \( v_2 \). Before defining an arc constraint, we first need to introduce simple arithmetic expressions as well as arithmetic expressions. Simple arithmetic expressions and arithmetic expressions are defined recursively.

**Simple arithmetic expressions**

A simple arithmetic expression is defined by one of the five following expressions.

- \( I \) : \( I \) is an integer.
- \( Arg \) : \( Arg \) is an argument of the global constraint of type int or dvar.
- \( Arg \) : \( Arg \) is a formal parameter provided by the arc generator\(^{16}\) of the graph-constraint.
- \( Col.Attr \) : \( Col \) is a formal parameter provided by the arc generator or the collection used in the For all items of iterator\(^{17}\) \( Attr \) is an attribute of the collection referenced by \( Col \).

\(^{16}\)Arc generators are described in Section 2.3.2 on page 61.

\(^{17}\)The For all items of iterator is described in Section 2.3.3 on page 80.
2. DESCRIBING GLOBAL CONSTRAINTS

EXAMPLE: As an example consider the first graph-constraint associated with the `GLOBAL_CARDINALITY_WITH_COSTS(VARIABLES, VALUES, MATRIX, COST)` constraint and its arc constraint variables.var = VALUES.val. Both, variables.var as well as VALUES.val are simple arithmetic expressions of the form Col.Attr:

- In variables.var, variables corresponds to the formal parameter provided by the arc generator `SELF ↦→ collection(variables)`, while var is an attribute of the VARIABLES collection.
- In VALUES.val, VALUES corresponds to the collection denoted by the For all items of iterator, while val is an attribute of the VALUES collection.

Arithmetic expressions

An arithmetic expression is recursively defined by one of the following expressions:

- A simple arithmetic expression.
- `Exp₁ Op Exp₂`
  - `Exp₁` is an arithmetic expression,
  - `Op` is one of the following symbols `+`, `−`, `∗`, `/\(^{18}\)`,
  - `Exp₂` is an arithmetic expression.
- `|Collection|`
  - Collection is an argument of type collection and `|Collection|` denotes the number of items of that collection.

\(^{18}\) / denotes an integer division, a division in which the fractional part is discarded.

• Col[Expr].Attr: Col is an argument of type collection, Attr one attribute of Col and Expr an arithmetic expression.

Col[Expr].Attr denotes the value of attribute Attr of the Expr\(^{\text{th}}\) item of the collection denoted by Col.

• Collection: collection is a collection of items of type (int, int, int) where all items are sorted in increasing order on attributes i, j (because of the restriction increasing_seq(MATRIX, [i, j])).

• MATRIX[(variables.key − 1) * |VALUES| + values.key].c denotes the value of attribute c of an item of the MATRIX collection. The position of this item within the MATRIX collection depends on the position of a variable of the VARIABLES collection as well as on the position of a value of the VALUES collection.

\(^{\text{a}}\)This position is denoted by the expression variables.key. As defined in Section 2.2.2 on page 16, key is an implicit attribute corresponding to the position of an item within a collection.

\(^{\text{b}}\)This position is denoted by the expression values.key.
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

- \(|\text{Exp}|\):
  - \text{Exp} is an arithmetic expression, and \(|\text{Exp}|\) denotes the absolute value of this expression.

- \text{sign(Exp)}:
  - \text{Exp} is an arithmetic expression, and \text{sign(Exp)} the sign of \text{Exp} (−1 if Exp is negative, 0 if Exp is equal to 0, 1 if Exp is positive).

  \textbf{EXAMPLE:} An example of use of \text{sign} can be found in the last part of the arc constraint of the \texttt{CROSSING} constraint:
  \[
  \text{sign}((s2.ox - s1.ex) \times (s1.ey - s1.oy) - (s1.ex - s1.ox) \times (s2.oy - s1.ey))
  \]

- \text{card\_set(Set)}:
  - \text{Set} is a reference to a set of integers or to a set variable. \text{card\_set(Set)} denotes the number of elements of that set.

  \textbf{EXAMPLE:} An example of use of \text{card\_set} can be found in the \texttt{SYMMETRIC\_GCC} constraint: \texttt{vars.nocc = card\_set(vars.var)}.

- \text{SimpleExp}_1 \text{ mod } \text{SimpleExp}_2,
  \text{min(}\text{SimpleExp}_1, \text{SimpleExp}_2\text{)} \text{ or } \text{max(}\text{SimpleExp}_1, \text{SimpleExp}_2\text{)}:
  - \text{SimpleExp}_1 is a simple arithmetic expression,
  - \text{SimpleExp}_2 is a simple arithmetic expression.

\textbf{Arc constraints}  Now that we have introduced simple arithmetic expressions as well as arithmetic expressions we define an arc constraint. An arc constraint is recursively defined by one of the following expressions:

- \text{TRUE}:
  This stands for an arc constraint that always holds. As a result, the corresponding arc always belongs to the final graph.

  \textbf{EXAMPLE:} An example of use of \texttt{TRUE} can be found in the \texttt{SUM\_CTR(VARIABLES, CTR, VAR)} constraint, where it is used in order to enforce keeping all items of the \texttt{VARIABLES} collection in the final graph.

- \text{Exp}_1 \text{ Comparison Exp}_2:
  - \text{Exp}_1 is an arithmetic expression,
  - \text{Comparison} is one of the comparison operators \(\leq, \geq, <, >, =, \neq\),
  - \text{Exp}_2 is an arithmetic expression.
As an example of such an arc constraint, the second graph-constraint of the CUMULATIVE(TASKS, LIMIT) constraint uses the following arc constraints:
- \( tasks_1.\text{duration} > 0 \),
- \( tasks_2.\text{origin} \leq tasks_1.\text{origin} \),
- \( tasks_1.\text{origin} < tasks_2.\text{end} \).

The conjunction of these three arc constraints can be interpreted in the following way: an arc from a task \( tasks_1 \) to a task \( tasks_2 \) will belong to the final graph if and only if \( tasks_2 \) overlaps the origin of \( tasks_1 \).

- **Exp \(_1\) SimpleCtr Exp \(_2\)**
  - **Exp \(_1\)** is an arithmetic expression,
  - **SimpleCtr** is an argument of type \( \text{atom} \) that can only take one of the values \( \leq, \geq, <, >, =, \neq \),
  - **Exp \(_2\)** is an arithmetic expression.

An example of use of such an arc constraint can be found in the CHANGE(NCHANGE, VARIABLES, CTR) constraint: \( \text{variables}_1.\text{var} \sim \text{CTR} \text{variables}_2.\text{var} \). Within this expression, \( \text{variables}_1 \) and \( \text{variables}_2 \) correspond to consecutive items of the VARIABLES collection.

- **Exp \(_1\) \neg SimpleCtr Exp \(_2\)**
  - **Exp \(_1\)** is an arithmetic expression,
  - **SimpleCtr** is an argument of type \( \text{atom} \) that can only take one of the values \( \leq, \geq, <, >, =, \neq \),
  - **Exp \(_2\)** is an arithmetic expression.

An example of use of such an arc constraint can be found in the CHANGECONTINUITY(NB_PERIOD_CHANGE, NB_PERIOD_CONTINUITY, MIN_SIZE_CHANGE, MAX_SIZE_CHANGE, MIN_SIZE_CONTINUITY, MAX_SIZE_CONTINUITY, NB_CHANGE, NB_CONTINUITY, VARIABLES, CTR) constraint: \( \text{variables}_1.\text{var} \sim \neg \text{CTR} \text{variables}_2.\text{var} \). Within this expression, \( \text{variables}_1 \) and \( \text{variables}_2 \) correspond to consecutive items of the VARIABLES collection.

- **constraint(Exp\(_1\),...,Exp\(_n\))**
  - **constraint** is a global constraint defined in the catalogue for which there exists a graph-based and/or an automaton-based representation,
  - **Exp\(_1\),...,Exp\(_n\)** correspond to the arguments of the global constraint **constraint**. Each argument should be a simple arithmetic expression that is compatible with the type declaration of the argument of **constraint**.
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

**EXAMPLE:** An example of such arc constraint can be found in the definition of \textsc{diffn}: \textsc{diffn}(\textsc{orthotopes}) uses the \texttt{TWO ORTH DO NOT OVERLAP(ORTHOTOPE1, ORTHOTOPE2)} global constraint for defining its arc constraint. Since \textsc{orthotopes} is a collection of type \texttt{collection(ori – dvar, siz – dvar, end – dvar)} and since both \textsc{orthotope1} and \textsc{orthotope2} correspond to items of \textsc{orthotopes} there is no type compatibility problem between the call to \texttt{TWO ORTH DO NOT OVERLAP} and its definition.

- \texttt{ArcCtr1 LogicalConnector ArcCtr2}
  - \texttt{ArcCtr1} is an arc constraint,
  - \texttt{LogicalConnector} is one of the logical connectors \texttt{∨}, \texttt{∧}, \texttt{⇒}, \texttt{⇔},
  - \texttt{ArcCtr2} is an arc constraint.

**EXAMPLE:** As shown by the following example, \textsc{minimum}(\texttt{min, variables}) uses this kind of arc constraint: \texttt{variables1 = variables2} \texttt{∨ variables1.var < variables2.var}, where \texttt{variables1} and \texttt{variables2} correspond to items of the \texttt{variables} collection, holds if and only if one of the following conditions holds:
  - \texttt{variables1} and \texttt{variables2} correspond to the same item of the \texttt{variables} collection,
  - The \texttt{var} attribute of \texttt{variables1} is strictly less than the \texttt{var} attribute of \texttt{variables2}.

**Graph generators**

This section describes how to generate the initial graph associated with a global constraint. Initial graphs correspond to directed hypergraphs [64], which have a very regular structure. They are defined in the following way:

- The vertices of the directed hypergraph are generated from collections of items such that each item corresponds to one vertex of the directed hypergraph. These collections are either collections that arise as arguments of the global constraint, or collections that are derived from one or several arguments of the global constraint. In this latter case these derived collections are computed by using the collection generators previously introduced (see Section 2.3.2 on page 51).

- To all arcs of the directed hypergraph corresponds the same arc constraint that involves vertices in a given order. These arc constraints, which are mainly unary and binary constraints, were described in the previous section (see Section 2.3.2 on page 57). We describe all the arcs of an initial graph with a set of predefined arc generators, which correspond to classical regular structures one can find in the graph literature [402, pages 140–153]. An arc generator of arity \( a \) takes \( n \) collections of items, denoted \( c_i(1 \leq i \leq n) \), as input and returns the corresponding hypergraph where the vertices are the items of the input collections.

---

\[^{19}\text{Usually the edges of a hypergraph are not oriented [64, pages 1–2]. However for our purpose we need to define an order on the vertices of an edge since the corresponding arc constraint takes its arguments in a given order.}\]
2. DESCRIBING GLOBAL CONSTRAINTS

\( c_i(1 \leq i \leq n) \) and where all arcs involve \( a \) vertices. Specific arc generators allow for giving an \( a \)-ary constraint for which \( a \) is not fixed, which means that the corresponding hypergraph contains arcs involving various number of vertices.

Each arc generator has a name and takes one or several collections of items as input and generates a set of arcs. Each arc is made from a sequence of items \( i_1 i_2 \ldots i_a \) and is denoted by \( (i_1, i_2, \ldots, i_a) \). \( a \) is called the arity of the arc generator. We have the following types of arc generators:

- Arc generators with a fixed predefined arity. In fact most arc generators have a fixed predefined arity of 2. The graphs they generate correspond to digraphs.

- Arc generators that can be used with any arity \( a \) greater than or equal to 1. These arc generators generate directed hypergraphs where all arcs consist of \( a \) items.

- Arc generators that generate arcs that do not involve the same number of items.

We now give the list of arc generators, listed in alphabetic order, and the arcs they generate. For each arc generator we point to a global constraint where it is used in practice. Finally, Figure 2.8 illustrates the different arc generators. At present the following arc generators are in use:

- **CHAIN** has a predefined arity of 2. It takes one collection \( c \) and generates the following arcs:\(^{20}\):

  \[- \forall i \in [1, |c| - 1]: (c[i], c[i + 1]), \quad - \forall i \in [1, |c| - 1]: (c[i + 1], c[i]).\]

**EXAMPLE:** The arc generator **CHAIN** is used, for example, in the **GROUP_SKIP_ISOLATED_ITEM** constraint.

- **CIRCUIT** has a predefined arity of 2. It takes one collection \( c \) and generates the following arcs:

  \[- \forall i \in [1, |c| - 1]: (c[i], c[i + 1]), \quad - (c[|c|], c[1]).\]

**EXAMPLE:** The arc generator **CIRCUIT** is used, for example, in the **CIRCULAR_CHANGE** constraint.

- **CLIQUE** can be used with any arity \( a \) greater than or equal to 2. It takes one collection \( c \) and generates the arcs: \( \forall i_1 \in [1, |c|], \forall i_2 \in [1, |c|], \ldots, \forall i_a \in [1, |c|] : (c[i_1], c[i_2], \ldots, c[i_a]) \).

**EXAMPLE:** The arc generator **CLIQUE** is usually used with an arity \( a = 2 \). For example, this is the case of the **ALLDIFFERENT** constraint.

---

\(^{20}\)As defined in Section 2.2.2 on page 16 we use the following notation: for a given collection \( c \), \( |c| \) and \( c[i] \) respectively denote the number of items of \( c \) and the \( i^{th} \) item of \( c \).
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

- **CLIQUE**(Comparison), where Comparison is one of the comparison operators ≤, ≥, <, >, =, ≠, can be used with any arity a greater than or equal to 2. It takes one collection c and generates the arcs:

  \[ \forall i_1 \in [1, |c|], \]
  \[ \forall i_2 \in [1, |c|] \text{ such that } i_1 \text{ Comparison } i_2, \]
  
  \[ \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \ldots \]
  \[ \forall i_a \in [1, |c|] \text{ such that } i_{a-1} \text{ Comparison } i_a : (c[i_1], c[i_2], \ldots, c[i_a]). \]

**Example:** The **ORCHARD(TREES)** constraint is an example of constraint that uses the **CLIQUE(<)** arc generator with an arity a = 3. It generates an arc for each set of three trees.

- **CYCLE** has a predefined arity of 2. It takes one collection c and generates the following arcs:

  - \[ \forall i \in [1, |c| - 1] : (c[i], c[i + 1]) \text{ and } (c[i + 1], c[i]), \]
  - \[ (c[c]), c[1]) \text{ and } (c[1], c[c]). \]

  The arc generator **CYCLE** is currently not used.

- **GRID**([d_1, d_2, \ldots, d_n]) takes a collection c consisting of \(d_1 \cdot d_2 \cdot \ldots \cdot d_n\) items and generates the arcs (c[i], c[j]) where i and j satisfy the following condition. There exists an integer \(\alpha\) (0 ≤ \(\alpha\) ≤ n − 1) such that (1) and (2) hold:

  \[ (1) |i - j| = \prod_{1 \leq k \leq \alpha} d_k \] (when \(\alpha = 0\) we have \(\prod_{1 \leq k \leq \alpha} = 1\),

  \[ (2) |\prod_{1 \leq k \leq \alpha+1} d_k| = |\prod_{1 \leq k \leq \alpha+1} d_k|. \]

  **Example:** The **CONNECT_POINTS** constraint uses the **GRID** arc generator.

- **LOOP** has a predefined arity of 2. It takes one collection c and generates the arcs: \(\forall i \in [1, |c|]: (c[i], c[i]). \)** **LOOP** is usually used in order to generate a loop on some vertices, so that they do not disappear from the final graph.

  **Example:** The **GLOBAL_CONTIGUITY(VARIABLES)** constraint is an example of constraint that uses the **LOOP** arc generator so that each variable of the VARIABLES collection belongs to the final graph.

- **PATH** can be used with any arity a greater than or equal to 1. It takes one collection c, and generates the following arcs: \(\forall i \in [1, |c| - a + 1] : (c[i], c[i + 1], \ldots, c[i + a - 1]). \)

  **Example:** **PATH** is used, for example, in the **SLIDING_SUM**(LOW, UP, SEQ, VARIABLES) constraint with an arity SEQ, where SEQ is an argument of the **SLIDING_SUM** constraint.
2. DESCRIBING GLOBAL CONSTRAINTS

- **PATH_1** generates arcs that do not involve the same number of items. It takes one collection \( c \), and generates the following arcs: \((c[1]), (c[2]), \ldots, (c[1], c[2], \ldots, c[|c|])\).

**EXAMPLE:** \( PATH_1 \) is used in the \( SIZE_MAX_STARTING_SEQ_ALLDIFFERENT \) constraint.

- **PATH_N** generates arcs that do not involve the same number of items. It takes one collection \( c \), and generates the following arcs: \( \forall i \in [1, |c|], \forall j \in [i, |c|] : (c[i], c[i+1], \ldots, c[j]) \).

**EXAMPLE:** \( PATH_N \) is used, for example, in the \( SIZE_MAX_SEQ_ALLDIFFERENT \) constraint.

- **PRODUCT** has a predefined arity of 2. It takes two collections \( c_1, c_2 \) and generates the arcs: \( \forall i \in [1, |c_1|], \forall j \in [1, |c_2|] : (c_1[i], c_2[j]) \).

**EXAMPLE:** \( PRODUCT \) is used, for example, in the \( SAME(VARIABLES1, VARIABLES2) \) constraint for generating an arc from every item of the \( VARIABLES1 \) collection to every item of the \( VARIABLES2 \) collection.

- **PRODUCT(Comparison)**, where Comparison is one of the comparison operators \( \leq, \geq, <, >, =, \neq \), has a predefined arity of 2. It takes two collections \( c_1, c_2 \) and generates the arcs: \( \forall i \in [1, |c_1|], \forall j \in [1, |c_2|] : (c_1[i], c_2[j]) \).

**EXAMPLE:** \( PRODUCT(=) \) is used, for example, in the \( DIFFER_FROM_AT_LEAST_K_POS(K, VECTOR1, VECTOR2) \) constraint in order to generate an arc between the \( i^{th} \) component of \( VECTOR1 \) and the \( i^{th} \) component of \( VECTOR2 \).

- **SELF** has a predefined arity of 1. It takes one collection \( c \) and generates the arcs: \( \forall i \in [1, |c|] : (c[i]) \).

**EXAMPLE:** \( SELF \) is used, for example, in the \( AMONG(NVAR, VARIABLES, VALUES) \) constraint in order to generate a unary arc constraint \( IN(variables.var, VALUES) \) for each variable of the \( VARIABLES \) collection.

- **SYMMETRIC_PRODUCT** has a predefined arity of 2. It takes two collections \( c_1, c_2 \) and generates the following arcs: \( \forall i \in [1, |c_1|], \forall j \in [1, |c_2|] : (c_1[i], c_2[j]) \) and \( (c_2[j], c_1[i]) \).

**EXAMPLE:** \( SYMMETRIC_PRODUCT \) is used, for example, in the \( INVERSE_WITHIN_RANGE \) constraint.

- **SYMMETRIC_PRODUCT(Comparison)**, where Comparison is one of the comparison operators \( \leq, \geq, <, >, =, \neq \), has a predefined arity of 2. It takes two collections \( c_1, c_2 \) and generates the arcs: \( \forall i \in [1, |c_1|], \forall j \in [1, |c_2|] \) such that \( i \) Comparison \( j : (c_1[i], c_2[j]) \) and \( (c_2[j], c_1[i]) \).
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

**EXAMPLE:** The `TWO ORTH DO NOT OVERLAP` constraint is an example of constraint that uses the `SYMMETRIC PRODUCT (=)` arc generator.

- **VOID** takes one collection and does not generate any arc.

**EXAMPLE:** `VOID` is used, for example, in the `LEX LESSEQ` constraint.

Finally, we can combine the `PRODUCT` arc generator with the arc generators from the following set $\mathcal{G}_{\text{enerator}} = \{\text{CIRCUIT}, \text{CHAIN}, \text{CLIQUE}, \text{LOOP}, \text{PATH}, \text{VOID}\}$. This is achieved by using the construction $\text{PRODUCT}(G_1, G_2)$ where $G_1$ and $G_2$ belong to $\mathcal{G}_{\text{enerator}}$. It applies $G_1$ to the first collection $c_1$ passed to $\text{PRODUCT}$ and $G_2$ to the second collection $c_2$ passed to $\text{PRODUCT}$. Finally, it applies $\text{PRODUCT}$ on $c_1$ and $c_2$. In a similar way the $\text{PRODUCT}(\text{Comparison})$ arc generator is extended to $\text{PRODUCT}(G_1, G_2, \text{Comparison})$.

**EXAMPLE:** As an illustrative example, consider the `ALLDIFFERENT SAME VALUE (NSAME, VARIABLES1, VARIABLES2)` constraint, which uses the arc generator $\text{PRODUCT(CLIQUE,LOOP,=)}$ on the collections $\text{VARIABLES1}$ and $\text{VARIABLES2}$. It generates the following arcs:

- Since the first argument of $\text{PRODUCT}$ is $\text{CLIQUE}$ it generates an arc between each pair of items of the $\text{VARIABLES1}$ collection.
- Since the second argument of $\text{PRODUCT}$ is $\text{LOOP}$ it generates a loop for each item of the $\text{VARIABLES2}$ collection.
- Since the third argument is the comparison operator $=$ it finally generates an arc between an item of the $\text{VARIABLES1}$ collection and an item of the $\text{VARIABLES2}$ collection when the two items have the same position.

Figure 2.7 shows the generated graph under the hypothesis that $\text{VARIABLES1}$ and $\text{VARIABLES2}$ have respectively 3 and 3 items.

![Figure 2.7](image-url)

**Figure 2.7:** Example of initial graph generated by $\text{PRODUCT(CLIQUE,LOOP,=)}$ when applied to collections $\text{VARIABLES1}$ and $\text{VARIABLES2}$

Figure 2.8 illustrates the different arc generators. On the one hand, for those arc generators that take a single collection, we apply them on the collection of items $\langle i - 1, i - 2, i - 3, i - 4 \rangle$. On the other hand, for those arc generators that take two collections, we apply them on $\langle i - 1, i - 2 \rangle$ and $\langle i - 3, i - 4 \rangle$. We use the following pictogram for the graphical representation of a constraint network:
2. DESCRIBING GLOBAL CONSTRAINTS

- A line for an arc constraint of arity 1,
- An arrow for an arc constraint of arity 2,
- A closed line for an arc constraint with an arity strictly greater than 2. In this last case, since the vertices of an arc are ordered, a black circle at one of the extremities indicates the direction of the closed line. For example, consider the example of PATH in Figure 2.8. The closed line that contains vertices 1, 2 and 3 means that a 3-ary arc constraint involves items 1, 2, and 3 in this specific order.

Dotted circles represent vertices that do not belong to the graph. This stems from the fact the arc generator did not produce any arc involving these vertices. The leftmost lowest corner indicates the arity of the corresponding arc generator:

- An integer if it has a fixed predefined arity,
- \( n \) if it can be used with any arity greater than or equal to 1,
- \( * \) if it generates arcs that do not necessarily involve the same number of items.

Figure 2.8: Examples of arc generators
Graph properties

We represent a global constraint as the search of a subgraph (i.e., a final graph) of a known initial graph, so that this final graph satisfies a given set of graph properties and possibly belongs to a specific graph class. Most graph properties have the form Parameter Comparison Exp or the form Parameter $\notin [\text{Exp}_1, \text{Exp}_2]$, where Parameter is a graph parameter [63], [208], Comparison is one of the comparison operators $=, <, \geq, >, \leq, \neq$, and Exp, Exp$_1$, Exp$_2$ are expressions that can be evaluated to an integer. Before defining each graph parameter, let’s first introduce some basic vocabulary on graphs.

Graph terminology and notations  A digraph $G = (V(G), E(G))$ is a pair where $V(G)$ is a finite set, called the set of vertices, and where $E(G)$ is a set of ordered pairs of vertices, called the set of arcs. The arc, path, circuit and strongly connected component of a graph $G$ correspond to oriented concepts, while the edge, chain, cycle and connected component are non-oriented concepts. However, as reported in [63, page 6] an undirected graph can be seen as a digraph where to each edge we associate the corresponding two arcs. Parts (A) and (B) of Figure 2.9 respectively illustrate the terms for undirected graphs and digraphs.

- We say that $e_2$ is a successor of $e_1$ if there exists an arc that starts from $e_1$ and ends at $e_2$. In the same way, we say that $e_2$ is a predecessor of $e_1$ if there exists an arc that starts from $e_2$ and ends at $e_1$.

- A vertex of $G$ that does not have any predecessor is called a source. A vertex of $G$ that does not have any successor is called a sink.

- A sequence $(e_1, e_2, \ldots, e_k)$ of edges of $G$ such that each edge has a common vertex with the previous edge, and the other vertex common to the next edge is called a chain of length $k$. A chain where all vertices are distinct is called an elementary chain. Each equivalence class of the relation “$e_i$ is equal to $e_j$ or
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

there exists a chain between $e_i$ and $e_j$” is a connected component of the graph $G$.

• A sequence $(e_1, e_2, \ldots, e_k)$ of arcs of $G$ such that, for each arc $e_i$ ($1 \leq i < k$) the end of $e_i$ is equal to the start of the arc $e_{i+1}$, is called a path of length $k$. A path where all vertices are distinct is called an elementary path. Each equivalence class of the relation “$e_i$ is equal to $e_j$ or there exists a path between $e_i$ and $e_j$” is a strongly connected component of the graph $G$.

• A chain $(e_1, e_2, \ldots, e_k)$ of $G$ is called a cycle if the same edge does not occur more than once in the chain and if the two extremities of the chain coincide. A cycle $(e_1, e_2, \ldots, e_k)$ of $G$ is called a circuit if for each edge $e_i$ ($1 \leq i < k$), the end of $e_i$ is equal to the start of the edge $e_{i+1}$.

• Given a graph $G$, we define the reduced graph $R(G)$ of $G$ as follows: to each strongly connected component of $G$ corresponds a vertex of $R(G)$; to each arc of $G$ that connects different strongly connected components corresponds an arc in $R(G)$ (multiple arcs between the same pair of vertices are merged).

• The rank function associated with the vertices $V(G)$ of a graph $G$ that does not contain any circuit is defined in the following way:
  
  – The rank of the vertices that do not have any predecessor (i.e., the sources) is equal to 0,
  
  – The rank $r$ of a vertex $v$ that is not a source is the length of longest path $(e_1, e_2, \ldots, e_r)$ such that the start of the arc $e_1$ is a source and the end of arc $e_r$ is the vertex $v$.

We now present the different notations used in the catalogue:

• $[k]$ corresponds to $\{1, \cdots, k\}$ for $k$ any positive integer.

• Given a set $X$, $|X|$ is the number of its elements.

• Given two sets $X$ and $Y$, $X \cup Y$ denotes the union of the two sets when they are disjoint.

• Given a digraph $G$ and $x \in V(G)$, $d_G^+(x) = |\{y : y \in V(G) : (x, y) \in E(G)\}|$ and $d_G^-(x) = |\{y : y \in V(G) : (y, x) \in E(G)\}|$.

• Given a digraph $G$ and $X$ a subset of $V(G)$, the sub-digraph of $G$ induced by $X$ is the digraph $G[X]$ where $V(G[X]) = X$ and $E(G[X]) = X^2 \cap E(G)$. By aim of simplicity, we denote $G[V(G) - X]$ by $G - X$. Moreover, if $X = \{x\}$, we use $G - x$ instead of $G - \{x\}$.

• Given two digraphs $G_1$ and $G_2$ such that $V(G_1) \cap V(G_2) = \emptyset$, $G_1 \oplus G_2$ denotes the graph whose vertices set is $V(G_1) \cup V(G_2)$ and whose arcs set is $E(G_1) \cup E(G_2)$.
Given a graph parameter $P \in \{\text{NCC}, \text{NSCC}\}$, a digraph $G$ and an integer $k$, $\text{CH}(G, k)$ is the number of connected components (respectively strongly connected components) of $G$ with cardinal $k$.

Given a graph parameter, for example, the number of connected components, $\text{NCC}_{\text{INITIAL}}$ denotes the number of connected components of the initial graph (i.e., the graph induced by the constraint under consideration), $\text{NCC}$ denotes the number of connected components of the final graph (i.e., a subgraph of the initial graph). $\text{NCC}(G)$ denotes the number of connected components of the digraph $G$.

Given a global constraint $C$, and a graph parameter $P$ used in the description of $C$, $P$ (respectively $\overline{P}$) denotes a lower bound (respectively upper bound) of $P$ among all possible final graphs compatible with the current status of $C$.

**Graph parameters** We list in alphabetic order the different graph parameters we consider for a final graph $G_f = (V(G_f), E(G_f))$ associated with a global constraint and give an example of constraint where they are used:

- **MAX_DRG**: largest distance between sources and sinks in the reduced graph associated with $G_f$ (adjacent vertices are at a distance of 1).

  **EXAMPLE:** We do not provide any example since MAX_DRG is currently not used.

- **MAX_ID**: number of predecessors of the vertex of $G_f$ that has the maximum number of predecessors without counting an arc from a vertex to itself.

  **EXAMPLE:** The CIRCUIT constraint uses the graph property $\text{MAX}_\text{ID} = 1$ in order to force each vertex of the final graph to have at most one predecessor.

- **MAX_NCC**: number of vertices of the largest connected component of $G_f$.

  **EXAMPLE:** The LONGEST_CHANGE($\text{SIZE}$, VARIABLES, $\text{CTR}$) constraint uses the graph property $\text{MAX}_\text{NCC} = \text{SIZE}$ in order to catch in $\text{SIZE}$ the maximum number of consecutive variables of the VARIABLES collection for which constraint $\text{CTR}$ holds.

- **MAX_NSCC**: number of vertices of the largest strongly connected component of $G_f$.

  **EXAMPLE:** The TREE constraint covers a digraph by a set of trees in such a way that each vertex belongs to a distinct tree. It uses the graph-property $\text{MAX}_\text{NSCC} \leq 1$ in order to avoid to have any circuit involving more than one vertex.
2.3. **Describing Global Constraints in Terms of Graph Properties**

- **MAX_OD**: number of successors of the vertex of $G_f$ that has the maximum number of successors without counting an arc from a vertex to itself.

  **Example**: The **TOUR** constraint forces to cover a graph with a Hamiltonian cycle. It uses the graph-property $\text{MAX_OD} = 2$ to enforce that each vertex of $G_f$ have at most two successors.

  “Since the **TOUR** constraint uses the $\text{CLIQUE}(\neq)$ arc generator the vertices of $G_f$ do not have any loop.

- **MIN_DRG**: smallest distance between sources and sinks in the reduced graph associated with $G_f$ (adjacent vertices are at a distance of 1).

  **Example**: We do not provide any example since **MIN_DRG** is currently not used by any constraint.

- **MIN_ID**: number of predecessors of the vertex of $G_f$ that has the minimum number of predecessors without counting an arc from a vertex to itself.

  **Example**: The **TOUR** constraint forces to cover a graph with a Hamiltonian cycle. It uses the graph-property $\text{MIN_ID} = 2$ to enforce that each vertex of $G_f$ have at most two predecessors.

  “Since the **TOUR** constraint uses the $\text{CLIQUE}(\neq)$ arc generator the vertices of $G_f$ do not have any loop.

- **MIN_NCC**: number of vertices of the smallest connected component of $G_f$.

  **Example**: Within the **GROUP** constraint, each connected component of $G_f$ corresponds to a maximum sequence of consecutive variables that take their values in a given set of values. Therefore, the graph-property $\text{MIN_NCC} = \text{MIN_SIZE}$ forces that the smallest sequence of such variables consist of $\text{MIN_SIZE}$ variables.
2. DESCRIBING GLOBAL CONSTRAINTS

- **MIN_NSCC**: number of vertices of the smallest strongly connected component of $G_f$.

  **EXAMPLE**: The $\text{CIRCUIT}(\text{NODES})$ constraint forces covering a digraph with one circuit visiting once all its vertices. The graph-property $\text{MIN_NSCC} = |\text{NODES}|$ forces that the smallest strongly connected component of $G_f$ contain $|\text{NODES}|$ vertices. Since $|\text{NODES}|$ also corresponds to the number of vertices of the initial graph this means that $G_f$ is a strongly connected component involving all the vertices. This is clearly a necessary condition for having a circuit visiting once all vertices.

  "Of course, this is not enough, and the description of the $\text{CIRCUIT}$ constraint asks for some other properties.

- **MIN_OD**: number of successors of the vertex of $G_f$ that has the minimum number of successors without counting an arc from a vertex to itself.

  **EXAMPLE**: The $\text{TOUR}$ constraint forces to cover a graph with a Hamiltonian cycle. It uses the graph-property $\text{MIN_OD} = 2$ to enforce that each vertex of $G_f$ have at most two succeedors.

  "Since the $\text{TOUR}$ constraint uses the $\text{CLIQUE}(\neq)$ arc generator the vertices of $G_f$ do not have any loop.

- **NARC**: cardinality of the set $E(G_f)$.

  **EXAMPLE**: The $\text{DISJOINT}(\text{VARIABLES1, VARIABLES2})$ constraint forces that each variable of the collection $\text{VARIABLES1}$ take a value that is distinct from all the values assigned to the variables of the collection $\text{VARIABLES2}$. This is imposed by creating an arc from each variable of $\text{VARIABLES1}$ to each variable of $\text{VARIABLES2}$. To each arc corresponds an equality constraint involving the variables associated with the extremities of the arc. Finally, the graph property $\text{NARC} = 0$ forces $G_f$ to be empty so that no value is both assigned to a variable of $\text{VARIABLES1}$ as well as to a variable of $\text{VARIABLES2}$.

- **NARC_NO_LOOP**: cardinality of the set $E(G_f)$ without considering the arcs linking the same vertex (i.e., a loop).

  **EXAMPLE**: The constraint $\text{ALLDIFFERENT_SAME_VALUE}$ uses the $\text{NARC_NO_LOOP}$ graph-property.

- **NCC**: number of connected components of $G_f$. 
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

**EXAMPLE:** The **TREE** constraint covers a digraph by \(\text{NTREES}\) trees in such a way that each vertex belongs to a distinct tree. It uses the graph-property \(\text{NCC} = \text{NTREES}\) in order to state that \(G_f\) is made up from \(\text{NTREES}\) connected components.

- **NSCC** : number of strongly connected components of \(G_f\).

**EXAMPLE:** The constraint \(\text{NVALUE}(\text{NVAL}, \text{VARIABLES})\) forces \(\text{NVAL}\) to be equal to the number of distinct values assigned to the variables of the collection \(\text{VARIABLES}\). This is enforced by using the graph-property \(\text{NSCC} = \text{NVAL}\). Each strongly connected component of the final graph corresponds to the variables that are assigned to the same value.

- **NSINK** : number of vertices of \(G_f\) that do not have any successor.

**EXAMPLE:** The \(\text{SAME}(\text{VARIABLES1}, \text{VARIABLES2})\) forces that the variables of the \(\text{VARIABLES1}\) collection correspond to the variables of the \(\text{VARIABLES2}\) collection according to a permutation.

We first create an arc from each variable of \(\text{VARIABLES1}\) to each variable of \(\text{VARIABLES2}\). To each arc corresponds an equality constraint involving the variables associated with the extremities of the arc. We use the graph-property \(\text{NSINK} = |\text{VARIABLES2}|\) in order to express the fact that each value assigned to a variable of \(\text{VARIABLES2}\) should also be assigned to a variable of \(\text{VARIABLES1}\).

- **NSINK_NSOURCE** : sum over the different connected components of \(G_f\) of the minimum of the number of sinks and the number of sources of a connected component.

**EXAMPLE:** The \(\text{SOFT\_SAME\_VAR}(C, \text{VARIABLES1}, \text{VARIABLES2})\) constraint forces \(C\) to be the minimum number of values to change in the \(\text{VARIABLES1}\) and the \(\text{VARIABLES2}\) collections of variables, so that the variables of \(\text{VARIABLES2}\) correspond to the variables of \(\text{VARIABLES1}\) according to a permutation.

A connected component \(C_{val}\) of the final graph \(G_f\) corresponds to all variables that are assigned to the same value \(val\): the sources and the sinks of \(C_{val}\) respectively correspond to the variables of \(\text{VARIABLES1}\) and to the variables of \(\text{VARIABLES2}\) that are assigned to \(val\). For a connected component, the minimum of the number of sources and sinks expresses the number of variables for which we do not need to make any change. Therefore we use the graph-property \(\text{NSINK\_NSOURCE} = |\text{VARIABLES1}| - C\) for encoding the meaning of the \(\text{SOFT\_SAME\_VAR}\) constraint.

\(^a\)Both collections have the same number of variables.
2. DESCRIBING GLOBAL CONSTRAINTS

• **NSOURCE**: number of vertices of $G_f$ that do not have any predecessor.

*EXAMPLE:* The `SAME(VARIABLES1, VARIABLES2)` forces that the variables of the `VARIABLES1` collection correspond to the variables of the `VARIABLES2` collection according to a permutation.

We first create an arc from each variable of `VARIABLES1` to each variable of `VARIABLES2`. To each arc corresponds an equality constraint involving the variables associated with the extremities of the arc. We use the graph-property `NSOURCE = |VARIABLES1|` in order to express the fact that each value assigned to a variable of `VARIABLES1` should also be assigned to a variable of `VARIABLES2`.

• **NTREE**: number of vertices of $G_f$ that do not belong to any circuit and for which at least one successor belongs to a circuit. Such vertices can be interpreted as root nodes of a tree.

*EXAMPLE:* The `CYCLE(NCYCLE, NODES)` forces that `NCYCLE` equal the number of circuits for covering an initial graph in such a way that each vertex belongs to a single circuit.

The graph-property `NTREE = 0` forces that all vertices of the final graph belong to a circuit.

• **NVERTEX**: cardinality of the set $V(G_f)$.

*EXAMPLE:* The `CUTSET(SIZE, CUTSET, NODES)` constraint considers a digraph with $n$ vertices described by the `NODES` collection. It forces that the subset of kept vertices of cardinality $n - SIZE_CUTSET$ and their corresponding arcs form a graph without a circuit. It uses the graph-property `NVERTEX = n - SIZE_CUTSET` for enforcing that the final graph $G_f$ contain the required number of vertices.

• **RANGE_DRG**: difference between the largest distance between sources and sinks in the reduced graph associated with $G_f$ and the smallest distance between sources and sinks in the reduced graph associated with $G_f$.

*EXAMPLE:* The `TREE_RANGE` constraint forces to cover a digraph in such a way that each vertex belongs to a distinct tree. In addition it forces the difference between the longest and the shortest paths of $G_f$ to be equal to the variable $R$. For this purpose it uses the graph-property `RANGE_DRG = R`.

• **RANGE_NCC**: difference between the number of vertices of the largest connected component of $G_f$ and the number of vertices of the smallest connected component of $G_f$.
2.3. **DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES**

**EXAMPLE:** We do not provide any example since `RANGE_NCC` is currently not used by any constraint.

- **RANGE_NSCC**: difference between the number of vertices of the largest strongly connected component of $G_f$ and the number of vertices of the smallest strongly connected component of $G_f$.

**EXAMPLE:** The `BALANCE` constraint forces `BALANCE` to be equal to the difference between the number of occurrences of the value that occurs the most and the value that occurs the least within the collection of variables `VARIABLES`. Each strongly connected component of $G_f$ corresponds to the variables that are assigned to the same value. The graph property `RANGE_NSCC = BALANCE` allows for expressing this definition.

- **ORDER**(rank, default, attr)
  - rank is an integer or an argument of type integer of the global constraint,
  - default is an integer,
  - attr is an attribute corresponding to an integer or to a domain variable that occurs in all the collections that were used for generating the vertices of the initial graph.

We explain what is the value associated with `ORDER(rank, default, attr)`. Let $V$ denotes the vertices of rank $rank$ of $G_f$ from which we remove any loops.

- When $V$ is not empty, it corresponds to the values of attribute `attr` of the items associated with the vertices of $V$,
- Otherwise, when $V$ is empty, it corresponds to the default value `default`.

**EXAMPLE:** The `MINIMUM` constraint forces `MIN` to be the minimum value of the collection of domain variables `VARIABLES`. There is an arc from a variable `var1` to a variable `var2` if and only if `var1 < var2`. The graph-property `ORDER(0, MAXINT, var) = MIN` expresses the fact that `MIN` is equal to the value of the source of $G_f$ (since $rank = 0$).

- **PATH_FROM_TO**(attr, from, to)
  - `attr` is an attribute corresponding to an integer that occurs in all the collections that were used for generating the vertices of the initial graph,
2. DESCRIBING GLOBAL CONSTRAINTS

- *from* is an integer or an argument of type integer of the global constraint.
- *to* is an integer or an argument of type integer of the global constraint.

Let \( F \) (respectively \( T \)) denotes the vertices of \( G_f \) such that \( attr \) is equal to \( from \) (respectively \( to \)). \( \text{PATH\_FROM\_TO}(attr, from, to) \) is equal to 1 if there exists a path between each vertex of \( F \) and each vertex of \( T \), and 0 if there exists no path between a vertex of \( F \) and a vertex of \( T \).

- *attr* is an attribute corresponding to an integer that occurs in all the collections that were used for generating the vertices of the initial graph.
- *from* is an attribute corresponding to an integer or to a set of integers that occurs in all the collections that were used for generating the vertices of the initial graph.
- *to* is an attribute corresponding to an integer or to a set of integers that occurs in all the collections that were used for generating the vertices of the initial graph.

For each vertex \( v \) of \( G_f \) let:

- \( \mathcal{F}_v \) the set of vertices for which the value of the attribute \( attr \) is equal to the \( from \) attribute (or is included within the \( from \) attribute when it corresponds to a set of integers).
- \( \mathcal{T}_v \) the set of vertices for which the value of the attribute \( attr \) is equal to the \( to \) attribute (or is included within the \( to \) attribute when it corresponds to a set of integers).

\( \text{PATH\_FROM\_TO}(attr, from, to) \) is equal to

- 1 if for each vertex of \( G_f \) there exists a path between each vertex of \( \mathcal{F}_v \) and each vertex of \( \mathcal{T}_v \).
- 0 if for a vertex of \( G_f \) there is no path between a vertex of \( \mathcal{F}_v \) and a vertex of \( \mathcal{T}_v \).

**EXAMPLE:** The constraints \( \text{LEX\_LESSEQ} \) and \( \text{STABLE\_COMPATIBILITY} \) use the \( \text{PATH\_FROM\_TO} \) graph-property.

* **PROD**\( (col, attr) \)

  - \( col \) is a collection that was used for generating the vertices of the initial graph.
  - \( attr \) is an attribute corresponding to an integer or to a domain variable of the collection \( col \).

Let \( V \) be the set of vertices of \( G_f \) that were generated from the items of the collection \( col \).
2.3. **DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES**

- If \( V \) is not empty, \( \text{PROD}(\text{col}, \text{attr}) \) corresponds to the product of the values of attribute \( \text{attr} \) associated with the vertices of \( V \),
- Otherwise, if \( V \) is empty, \( \text{PROD}(\text{col}, \text{attr}) \) is equal to 1.

**EXAMPLE:** The constraint \( \text{PRODUCT}_{\text{CTR}}(\text{VARIABLES}, \text{CTR}, \text{VAR}) \) forces the product of the variables of the \( \text{VARIABLES} \) collection to be equal, less than or equal, ... to a given domain variable \( \text{VAR} \).

To each variable of \( \text{VARIABLES} \) corresponds a vertex of the initial graph. Since we want to keep all the vertices of the initial graph we use the \( \text{SELF} \) arc generator together with the \( \text{TRUE} \) arc constraint. Finally, \( \text{PROD}(\text{VARIABLES}, \text{var}) \) \( \text{CTR} \) \( \text{VAR} \) expresses the required condition. In this expression \( \text{var} \) and \( \text{CTR} \) respectively corresponds to the attribute of the collection \( \text{VARIABLES} \) (a domain variable) and to the condition we want to enforce. Since the final graph \( G_f \) contains all the vertices of the initial graph, the expression \( \text{PROD}(\text{VARIABLES}, \text{var}) \) corresponds to the product of the variables of the \( \text{VARIABLES} \) collection.

- \( \text{RANGE}(\text{col}, \text{attr}) \)

  - \( \text{col} \) is a collection that was used for generating the vertices of the initial graph,
  - \( \text{attr} \) is an attribute corresponding to an integer or to a domain variable of the collection \( \text{col} \).

Let \( V \) be the set of vertices of \( G_f \) that were generated from the items of the collection \( \text{col} \).

- If \( V \) is not empty, \( \text{RANGE}(\text{col}, \text{attr}) \) corresponds to the difference between the maximum and the minimum values of attribute \( \text{attr} \) associated with the vertices of \( V \),
- Otherwise, if \( V \) is empty, \( \text{RANGE}(\text{col}, \text{attr}) \) is equal to 0.

**EXAMPLE:** The constraint \( \text{RANGE}_{\text{CTR}}(\text{VARIABLES}, \text{CTR}, \text{VAR}) \) forces the difference between the maximum value and the minimum value of the variables of the \( \text{VARIABLES} \) collection to be equal, less than or equal, ... to a given domain variable \( \text{VAR} \).

To each variable of \( \text{VARIABLES} \) corresponds a vertex of the initial graph. Since we want to keep all the vertices of the initial graph we use the \( \text{SELF} \) arc generator together with the \( \text{TRUE} \) arc constraint. Finally, \( \text{RANGE}(\text{VARIABLES}, \text{var}) \) \( \text{CTR} \) \( \text{VAR} \) expresses the required condition. In this expression \( \text{var} \) and \( \text{CTR} \) respectively corresponds to the attribute of the collection \( \text{VARIABLES} \) (a domain variable) and to the condition we want to enforce. Since the final graph \( G_f \) contains all the vertices of the initial graph, the expression \( \text{RANGE}(\text{VARIABLES}, \text{var}) \) corresponds to the difference between the maximum value and the minimum value of the variables of the \( \text{VARIABLES} \) collection.
• **SUM(col, attr)**
  - col is a collection that was used for generating the vertices of the initial graph.
  - attr is an attribute corresponding to an integer or to a domain variable of the collection col.

Let $\mathcal{V}$ be the set of vertices of $G_f$ that were generated from the items of the collection col.

- If $\mathcal{V}$ is not empty, $\text{SUM}(\text{col}, \text{attr})$ corresponds to the sum of the values of attribute attr associated with the vertices of $\mathcal{V}$.
- Otherwise, if $\mathcal{V}$ is empty, $\text{SUM}(\text{col}, \text{attr})$ is equal to 0.

**EXAMPLE:** The constraint $\text{SUM_CTR}(\text{VARIABLES}, \text{CTR}, \text{VAR})$ forces the sum of the variables of the VARIABLES collection to be equal, less than or equal, ... to a given domain variable VAR.

To each variable of VARIABLES corresponds a vertex of the initial graph. Since we want to keep all the vertices of the initial graph we use the SELF arc generator together with the TRUE arc constraint. Finally, $\text{SUM}(\text{VARIABLES}, \text{VAR})$ CTR VAR expresses the required condition. In this expression VAR and CTR respectively correspond to the attribute of the collection VARIABLES (a domain variable) and to the condition we want to enforce. Since the final graph $G_f$ contains all the vertices of the initial graph, the expression $\text{SUM}(\text{VARIABLES}, \text{VAR})$ corresponds to the sum of the variables of the VARIABLES collection.

• **SUM_WEIGHT_ARC(Expr)**  
  Expr is an arithmetic expression.  
  For each arc $a$ of $E(G_f)$, let $f(a)$ denotes the value of Expr. $\text{SUM_WEIGHT_ARC}(\text{Expr})$ is equal to $\sum_{a \in E(G_f)} f(a)$. The value of Expr usually depends on the attributes of the items located at the extremities of an arc.

**EXAMPLE:** The constraint $\text{GLOBAL_CARDINALITY_WITH_COSTS}(\text{VARIABLES, VALUES, MATRIX, COST})$ forces that each value $\text{VALUES}[i].\text{val}$ be assigned to exactly $\text{VALUES}[i].\text{occurrence}$ variables of the VARIABLES collection. In addition the COST of an assignment is equal to the sum of the elementary costs associated with the fact that we assign the $i^{th}$ variable of the VARIABLES collection to the $j^{th}$ value of the VALUES collection. These elementary costs are given by the MATRIX collection.

The graph-property $\text{SUM_WEIGHT_ARC}(\text{MATRIX}[\text{variables.key} - 1] \ast \text{size}(\text{VALUES}) + \text{values.key}).c) = \text{COST}$ expresses that the COST variable is equal to the sum of the elementary costs associated with each variable-value assignment. All these elementary costs are recorded in the MATRIX collection. More precisely, the cost $c_{ij}$ is recorded in the attribute c of the $((i - 1) \ast |\text{VALUES}| + j)^{th}$ entry of the MATRIX collection.

A last graph parameter, **DISTANCE**, is computed on two final graphs $G_1$ and $G_2$ that have the same set $V$ of vertices and the sets $E(G_1)$ and $E(G_2)$ of arcs. This
2.3. DESCRIBING GLOBAL CONSTRAINTS IN TERMS OF GRAPH PROPERTIES

A graph parameter is the cardinality of the set \((E(G_1) - E(G_2)) \cup (E(G_2) - E(G_1))\). This corresponds to the number of arcs that belong to \(E(G_1)\) but not to \(E(G_2)\), plus the number of arcs that are in \(E(G_2)\) but not in \(E(G_1)\).

**Graph class**  For a given global constraint, a graph class specifies a general property that holds on its final digraph. We list the different graph classes and, for each of them, we point to some global constraints that fit in that class. Finding all the global constraints corresponding to a given graph class can be done by looking into the list of keywords (see Section 3.7 on page 161).

- **ACYCLIC**: the final graph does not have any circuit.
- **BIPARTITE**: the final graph is bipartite.
- **CONSECUTIVE LOOPS ARE CONNECTED**: denotes that the graph constraint of a global constraint uses only the **PATH** and the **LOOP** arc generators and that the final graph does not contain consecutive vertices that have a loop and that are not connected together by an arc.
- **EQUIVALENCE**: the final graph is reflexive, symmetric and transitive.
- **NO LOOP**: the final graph does not have any loop.
- **ONE SUCC**: the vertices of the initial graph belong to the final graph and all vertices of the final graph have exactly one successor.
- **SYMMETRIC**: the final graph is symmetric. A digraph is symmetric if and only if, if there is an arc from a vertex \(u\) to a vertex \(v\), there is also an arc from \(v\) to \(u\).
2. DESCRIBING GLOBAL CONSTRAINTS

2.3.3 Graph constraint

A global constraint can be defined as a conjunction of several simple or dynamic graph constraints\(^\text{21}\) that all share the same name, the same arguments and the same argument restrictions.\(^\text{22}\) This section first describes simple graph constraints and then dynamic graph constraints, which are an extension of simple graph constraints.

Simple graph constraint

To a simple graph constraint correspond several initial graphs, usually one, where all the initial graphs have the same vertices and arcs. Specifying more than one initial graph is usually\(^\text{23}\) achieved by using the FOR ALL ITEMS OF iterator (e.g., see the definition of the GLOBAL CARDINALITY constraint), which takes a collection \(C\) and generates an initial graph \(G_i(t)\) for each item \(t\) of \(C\). In this context, the arc constraints and/or graph properties of an initial graph may depend of the attributes of the item \(t\) of \(C\) from which they were generated. All arc constraints attached to a given arc\(^\text{24}\) have to be pairwise mutually incompatible.\(^\text{25}\)

The graphs of a simple graph constraint are defined by the following slots:

- An **Arc input(s)** slot, which consists of:
  - Either a sequence of collections \(C_1, C_2, \ldots, C_d\) (\(d \geq 1\)). To each item of these collections corresponds a vertex of the initial graph (i.e., in this context we generate a single initial graph).
  - Either a list of sequences of collections. To each item of the collections of a given sequence corresponds a vertex of one of the initial graphs (i.e., in this context we generate one initial graph for each sequence\(^\text{26}\)).

- An **Arc generator** slot, which can be one or several expressions\(^\text{27}\) of the following forms:
  - \(ARC\_GENERATOR \mapsto collection(item_1, item_2, \ldots, item_a)\), where \(ARC\_GENERATOR\) is one of the arc generators with a fixed arity\(^\text{28}\) defined in Section 2.3.2 on page 61, and \(item_i\) (\(1 \leq i \leq a\)) denotes the \(i\)th item associated with the \(i\)th vertex of an arc. These items correspond to formal parameters\(^\text{29}\) which can be used within an arc constraint.

\(^{21}\)For an example of a global constraint that is defined by more than one graph constraint see, for instance, the SORT constraint and its two graph constraints.

\(^{22}\)The arguments and the argument restrictions were described in Section 2.2.4 on page 26.

\(^{23}\)Another way of generating several initial graphs will be explained later on in the Arc input(s) slot.

\(^{24}\)As we previously said, even though we have more than one initial graph, all vertices and arcs of the different initial graphs are identical.

\(^{25}\)Two arc constraints \(\text{constraint}_1(X_1, X_2, \ldots, X_n)\) and \(\text{constraint}_2(X_1, X_2, \ldots, X_n)\) are incompatible if there does not exist any tuple of values \((v_1, v_2, \ldots, v_n)\) such that both \(\text{constraint}_1(X_1, X_2, \ldots, X_n)\) and \(\text{constraint}_2(X_1, X_2, \ldots, X_n)\) hold.

\(^{26}\)This is the case, for example, for the DISTANCE_BETWEEN constraint.

\(^{27}\)Usually a single expression.

\(^{28}\)Any arc generator different from \(PATH\_1\) and \(PATH\_N\).

\(^{29}\)See the description of simple arithmetic expressions page 57.
When the Arc input(s) slot consists of a single collection \((d = 1)\), \(\text{item}_i\) \((1 \leq i \leq a)\) represents an item of the collection \(C_1\). Otherwise, when \(d > 1\), we must have \(a = d\) and, in this context, \(\text{item}_i\) \((1 \leq i \leq a)\) represents an item of \(C_i\).

**EXAMPLE:** The **ALLDIFFERENT(VARIABLES)** constraint has the following Arc input(s) and Arc generator slots:

- Its Arc input(s) slot refers only to the collection **VARIABLES** (i.e., \(d = 1\)).
- Its Arc generator slot consists of **CLIQUE** \(\rightarrow\) **collection** \((\text{variables}_1, \text{variables}_2)\) (i.e., \(a = 2\)).

In this context, where \(d = 1\), both \(\text{variables}_1\) and \(\text{variables}_1\) are items of the **VARIABLES** collection.

**EXAMPLE:** The **SAME(VARIABLES1, VARIABLES2)** constraint has the following Arc input(s) and Arc generator slots:

- Its Arc input(s) slot refers to the collections **VARIABLES1** and **VARIABLES2** (i.e., \(d = 2\)).
- Its Arc generator slot consists of **PRODUCT** \(\rightarrow\) **collection** \((\text{variables}_1, \text{variables}_2)\) (i.e., \(a = 2\)).

In this context, where \(d > 1\), \(\text{variables}_1\) and \(\text{variables}_1\) respectively correspond to items of the **VARIABLES1** and the **VARIABLES2** collections.

- **ARC_GENERATOR** \(\rightarrow\) **collection**, where **ARC_GENERATOR** is one of the arc generators **PATH_1** or **PATH_N**. In this context, **collection** denotes a collection of items corresponding to the vertices of an arc of the initial graph. An arc constraint forces a restriction on the items of this collection.

**EXAMPLE:**
The **SIZE_MAX_SEQ_ALLDIFFERENT** (SIZE, **VARIABLES**) constraint has the following Arc input(s) and Arc generator slots:

- Its Arc input(s) slot refers to the **VARIABLES** collection.
- Its Arc generator slot consists of **PRODUCT** \(\rightarrow\) **collection**.

In this context, **collection** is a collection of the same type as the **VARIABLES** collection. It corresponds to the variables associated with an arc of the initial graph.

When the Arc generator slot consists of \(n\) \((n > 1)\) expressions then these expressions have the form:

\[
\begin{align*}
ARC\_GENERATOR_1 & \rightarrow \text{collection} (\text{item}_1, \text{item}_2, \ldots, \text{item}_a) \\
ARC\_GENERATOR_2 & \rightarrow \text{collection} (\text{item}_1, \text{item}_2, \ldots, \text{item}_a) \\
\vdots & \\
ARC\_GENERATOR_n & \rightarrow \text{collection} (\text{item}_1, \text{item}_2, \ldots, \text{item}_a)
\end{align*}
\]

All leftmost part of the expressions must be the same since they will be involved in a single Arc constraint(s) slot. The **GLOBAL_CONTIGUITY** constraint is an
example of global constraint where more than one arc generator is used.

- An **Arc arity** slot, which corresponds to the number of vertices $a$ of each arc of the initial graph. $a$ is either a strictly positive integer, an argument of the global constraint of type `int`, or the character `*`. In this last case, this is used for denoting that all the arc constraints do not involve the same number of vertices. This is the case, for example, when we use the arc generators `PATH_1` or `PATH_N` as in the `ARITH_SLIDING` or the `SIZE_MAX_SEQ_ALLDIFFERENT` constraints.

- An **Arc constraint(s)** slot, which corresponds to a conjunction of arc constraints\(^{30}\) those were introduced in Section 2.3.2 on page 57.

- A **Graph property(ies)** slot, which corresponds to one or several graph properties (see Section 2.3.2 on page 68) to be satisfied on the final graphs associated with an instantiated solution to the global constraint. To each initial graph corresponds one final graph obtained by removing all arcs for which the corresponding arc constraints do not hold as well as all vertices that do not have any arc.

We now give several examples of descriptions of simple graph constraints, starting from the `NVALUE` constraint, which was introduced as a first example of global constraint that can be modelled by a graph property in Section 2.3.1 on page 48.

```
EXAMPLE: The constraint NVALUE(NVAL, VARIABLES) restricts NVAL to be the number of distinct values taken by the variables of the collection VARIABLES. Its meaning is described by a simple graph constraint corresponding to the following items:

- **Arc input(s)**: VARIABLES
- **Arc generator**: CLIQUE $\rightarrow$ collection(variables1,variables2)
- **Arc arity**: 2
- **Arc constraint(s)**: variables1.var = variables2.var
- **Graph property(ies)**: NSCC = NVAL

Since this description does not use the FOR ALL ITEMS OF iterator we generate a single initial graph. Each vertex of this graph corresponds to one item of the VARIABLES collection. Since we use the CLIQUE arc generator we have an arc between each pair of vertices. An arc constraint corresponds to an equality constraint between the two variables that are associated with the extremities of the arc. Finally, the **Graph property(ies)** slot forces the final graph to have NVAL strongly connected components.
```

\(^{30}\)Usually this conjunction consists of a single **arc constraint**.
EXAMPLE: The constraint `GLOBAL_CONTIGUITY(VARIABLES)` forces all variables of the `VARIABLES` collection to be assigned to 0 or 1. In addition, all variables assigned to value 1 appear contiguously. Its meaning is described by a simple graph constraint corresponding to the following items:

- **Arc input(s):** `VARIABLES`
- **Arc generator:**
  - `PATH` \(\mapsto\) `collection(variables1, variables2)`
  - `LOOP` \(\mapsto\) `collection(variables1, variables2)`
- **Arc arity:** 2
- **Arc constraint(s):**
  - `variables1.var = variables2.var`
  - `variables1.var = 1`
- **Graph property(ies):** `NCC \leq 1`

Since this description does not use the `FOR ALL ITEMS OF` iterator we generate a single initial graph. Each vertex of this graph corresponds to one item of the `VARIABLES` collection. Since we use the `PATH` arc generator we generate an arc from item `VARIABLES[i]` to item `VARIABLES[i + 1]` (1 \(\leq i < |VARIABLES|\)). In addition, since we use the `LOOP` arc generator, we generate also an arc from each item of the `VARIABLES` collection to itself.

The effect of the arc constraint is to keep in the final graph those vertices for which the corresponding variable is assigned to 1. Adjacent variables assigned to 1 form a connected component of the final graph and the graph property `NCC \leq 1` forces to have at most one such group of adjacent variables assigned to 1.

*We use the `LOOP` arc generator in order to keep in the final graph those isolated variables assigned to 1. This is because isolated vertices with no arcs are always removed from the final graph.*

EXAMPLE:
The `GLOBAL_CARDINALITY(VARIABLES, VALUES)` constraint forces that each value `VALUES[i].val` (1 \(\leq i \leq |VALUES|\)) be taken by exactly `VALUES[i].noccurrence` variables of the `VARIABLES` collection. Its meaning is described by a simple graph constraint corresponding to the following items:

- **For all items of VALUES:**
  - **Arc input(s):** `VARIABLES`
  - **Arc generator:** `SELF` \(\mapsto\) `collection(variables)`
  - **Arc arity:** 1
  - **Arc constraint(s):** `variables.var = VALUES.val`
- **Graph property(ies):** `NVERTEX = VALUES.noccurrence`

Since this description uses the `FOR ALL ITEMS OF` iterator on the `VALUES` collection we generate an initial graph for each item of the `VALUES` collection (i.e., one graph for each value). Each vertex of an initial graph corresponds to one item of the `VARIABLES` collection. Since we use the `SELF` arc generator we have an arc for each vertex. For an initial graph associated with a value `val` an arc constraint on a vertex `v` corresponds to an equality constraint between the variable associated with `v` and the value `val`. Finally, the **Graph property(ies)** slot forces the final graph to have a given number of vertices (i.e., associated with the attribute `val`).
2. DESCRIBING GLOBAL CONSTRAINTS

Dynamic graph constraint

The purpose of a dynamic graph constraint is to enforce a condition on different subsets of variables, not known in advance. This situation occurs frequently in practice and is hard to express since one cannot use a classical constraint for which it is required to provide all variables right from the beginning. One good example of such global constraint is the \texttt{CUMULATIVE} constraint where one wants to force the sum of some variables to be less than or equal to a given limit. In the context of the \texttt{CUMULATIVE} constraint, each set of variables is defined by the height of the different tasks that overlap a given instant $i$. Since the origins of the tasks are not initially fixed, we do not know in advance which task will overlap a given instant and so, we cannot state any sum constraint initially.

A dynamic graph constraint is defined in exactly the same way as a simple graph constraint, except that we may omit the \texttt{Graph property(ies)} slot, and that we have to provide the two following additional slots:

- The \texttt{Set} slot denotes a generator of sets of vertices. Such a generator takes as argument a final graph and produces different sets of vertices. In order to have something tractable, we force the total number of generated sets to be polynomial in the number of vertices.

  In practice each set of vertices is represented by a collection of items. The type of this collection corresponds either to the type of the items associated with the vertices, or to the type of a new derived collection. This is achieved by providing an expression of the form \texttt{name} or \texttt{name-derived}\_collection, where \texttt{name} represents a formal parameter, and \texttt{derived}\_collection a declaration of a new derived collection (as specified in Section 2.3.2 on page 51).

- The \texttt{Constraint(s) on sets} slot provides a global constraint defined in the catalogue that has to hold for each set created by the previous generator.

We now describe the different generators of sets of vertices currently available:

- \texttt{ALL\_VERTICES} generates a single set containing all the vertices of the final graph. It is specified by a declaration of the form
  \begin{verbatim}
  ALL\_VERTICES>> [vertices]
  \end{verbatim}
  where \texttt{vertices} represents all the vertices of the final graph.

- \texttt{CC} generates one set of vertices for each connected component of the final graph. These sets correspond to all the vertices of a given connected component. It is specified by a declaration of the form
  \begin{verbatim}
  CC>> [connected\_component]
  \end{verbatim}
  where \texttt{connected}\_component represents the vertices of a connected component of the final graph.

- \texttt{PATH\_LENGTH($L$)} generates all elementary paths\footnote{A path where all vertices are distinct is called an elementary path.} of $L$ vertices of the final graph such that, discarding loops, all vertices of a path (except the last one) have
no more than one successor in the final graph. It is specified by a declaration of the form

\[
\text{PATH\_LENGTH}(L) >> \text{[path]}
\]

where \text{path} represents the vertices of an elementary path, ordered according to their occurrences in the path.

- **PRED** generates the non-empty sets corresponding to the predecessors of each vertex of the final graph. It is specified by a declaration of the form

\[
\text{PRED} >> \text{[predecessor, destination]}
\]

where \text{destination} represents a vertex of the final graph and \text{predecessor} its predecessors.

- **SUCC** generates the non-empty sets corresponding to the successors of each vertex of the final graph. It is specified by a declaration of the form

\[
\text{SUCC} >> \text{[source, successor]}
\]

where \text{source} represents a vertex of the final graph and \text{successor} its successors.

As an illustrative example of *dynamic graph constraint* we now consider the **CUMULATIVE** constraint.
EXAMPLE: The \texttt{CUMULATIVE}(\texttt{TASKS,LIMIT}) constraint, where \texttt{TASKS} is a collection of the form \texttt{collection(origin−dvar,\text{duration}−dvar,\text{end}−dvar,\text{height}−dvar)}, and where \texttt{LIMIT} is a non-negative integer, holds if, for any point the cumulated height of the set of tasks that overlap that point, does not exceed \texttt{LIMIT}.

The first graph constraint of \texttt{CUMULATIVE} forces for each task of the \texttt{TASKS} collection the equality \texttt{origin + duration = end}. We focus on the second graph constraint, which uses a \textit{dynamic graph constraint} described by the following items:

- **Arc input(s)**: \texttt{TASKS TASKS}
- **Arc generator**: \texttt{PRODUCT} ↦ \texttt{collection(tasks1,tasks2)}
- **Arc arity**: 2
- **Arc constraint(s)**:
  - \texttt{tasks1.duration > 0}
  - \texttt{tasks2.origin \leq tasks1.origin}
  - \texttt{tasks1.origin \leq tasks2.end}

- **Sets**: \texttt{SUCC}>>
  - \texttt{variables − col(VARIABLES − collection(var − dvar), [item(var − TASKS.height)])}
- **Constraint(s) on sets**: \texttt{SUM_CTR}(variables, ≤, \text{LIMIT})

The second graph constraint is defined by:

- To each item of the \texttt{TASKS} collection correspond two vertices of the initial graph.
- The arity of the arc constraint is 2.
- The arcs of the initial graph are constructed with the \texttt{PRODUCT} arc generator between the \texttt{TASKS} collection and the \texttt{TASKS} collection. Therefore, each vertex associated with a task is linked to all the vertices related to the different tasks.
- The arc constraint that is associated with an arc between a task \texttt{tasks1} and a task \texttt{tasks2} is an overlapping constraint that holds if both, the duration of \texttt{tasks1} is strictly greater than zero, and if the origin of \texttt{tasks1} is overlapped by task \texttt{tasks2}.
- The set generator is \texttt{SUCC}. The final graph will consist of those tasks for which the origin is covered by at least one task and of those corresponding tasks.
- The dynamic constraint on a set forces the sum of the heights of the tasks that belong to a successor set to not exceed \texttt{LIMIT}. 
Figure 2.10: Initial and final graph of an instance of the CUMULATIVE constraint

Parts (A) and (B) of Figure 2.10 respectively show the initial and the final graph corresponding to the following instance:

\[
\text{CUMULATIVE}((\text{origin} - 1 \text{ duration} - 3 \text{ height} - 1, \\
\text{origin} - 2 \text{ duration} - 9 \text{ height} - 2, \\
\text{origin} - 3 \text{ duration} - 10 \text{ height} - 1, \\
\text{origin} - 6 \text{ duration} - 6 \text{ height} - 1, \\
\text{origin} - 7 \text{ duration} - 2 \text{ height} - 3), 8).)
\]

We label the vertices of the initial and final graph by giving the key of the corresponding task. On both graphs the edges are oriented from left to right. On the final graph we consider the sets that consist of the successors of the different vertices; those are the sets of tasks \(\{1\}\), \(\{1, 2\}\), \(\{1, 2, 3\}\), \(\{2, 3, 4\}\) and \(\{2, 3, 4, 5\}\). Since the SUCC set generator uses a derived collection that only considers the height attribute of a task, these sets respectively correspond to the following collection of items:

- \((\text{var} - 1)\),
- \((\text{var} - 1, \text{var} - 2)\),
- \((\text{var} - 1, \text{var} - 2, \text{var} - 1)\),
- \((\text{var} - 2, \text{var} - 1, \text{var} - 1)\),
- \((\text{var} - 2, \text{var} - 1, \text{var} - 1, \text{var} - 3)\).

The CUMULATIVE constraint holds since, for each successors set, the corresponding constraint holds:

- \(\text{SUM}_\text{CTR}((\text{var} - 1), \leq, 8)\),
- \(\text{SUM}_\text{CTR}((\text{var} - 1, \text{var} - 2), \leq, 8)\),
- \(\text{SUM}_\text{CTR}((\text{var} - 1, \text{var} - 2, \text{var} - 1), \leq, 8)\),
- \(\text{SUM}_\text{CTR}((\text{var} - 2, \text{var} - 1, \text{var} - 1), \leq, 8)\),
- \(\text{SUM}_\text{CTR}((\text{var} - 2, \text{var} - 1, \text{var} - 1, \text{var} - 3), \leq, 8)\).

The \(\text{SUM}_\text{CTR}(\text{VARIABLES}, \text{CTR}, \text{VAR})\) constraint holds if the sum \(S\) of the variables of the VARIABLES collection satisfies \(S \text{CTR} \text{VARIABLES}\), where \(\text{CTR}\) is a comparison operator.

\(^{a}\text{key is an implicit attribute corresponding to the position of an item within a collection that was introduced in Section 2.2.2 on page 16.}\)
2.4 Describing global constraints in terms of automata

This section is based on the article describing global constraint in terms of automata [39]. The main difference from the original article is the introduction of array of counters within the description of an automaton. We consider global constraints for which any ground instance can be checked in linear time by scanning once through their variables without using any data structure, except counters or arrays of counters. In order to concretely illustrate this point we first select a set of global constraints and write down a checker for each of them. Finally, we give for each checker a sketch of the corresponding automaton. Based on these observations, we define the type of automaton we use in the catalogue.

2.4.1 Selecting an appropriate description

As we previously said, we focus on those global constraints that can be checked by scanning once through their variables. This is the case, for example, of:

- `ELEMENT [429]`,
- `MINIMUM [29]`,
- `PATTERN [92]`,
- `GLOBAL_CONTIGUITY [282]`,
- `LEX_LESSEQ [184]`,
- `AMONG [47]`,
- `INPLEXION [27]`,
- `ALLDIFFERENT [351]`.

Since they illustrate key points needed for characterising the set of solutions associated with a global constraint, our discussion will be based on the last five constraints for which we now recall the definition:

- The `GLOBAL_CONTIGUITY(vars)` constraint forces the sequence of 0-1 variables `vars` to have at most one group of consecutive 1. For example, the constraint `GLOBAL_CONTIGUITY(⟨0, 1, 1⟩)` holds since we have only one group of consecutive 1.

- The lexicographic ordering constraint `x \leq_{\text{lex}} y` (see `LEX_LESSEQ`) over two vectors of variables `x = ⟨x_0, \ldots, x_{n-1}⟩` and `y = ⟨y_0, \ldots, y_{n-1}⟩` holds if and only if `n = 0` or `x_0 < y_0` or `x_0 = y_0` and `⟨x_1, \ldots, x_{n-1}⟩ \leq_{\text{lex}} ⟨y_1, \ldots, y_{n-1}⟩`.

- The `AMONG(nvar, vars, values)` constraint restricts the number of variables of the sequence of variables `vars` that take their values in a given set `values`, to be equal to the variable `nvar`. For example, `AMONG(3, ⟨4, 5, 5, 4, 1⟩, ⟨1, 5, 8⟩)` holds since exactly 3 values of the sequence `45541` are located in the set of values `{1, 5, 8}`.

- The `INPLEXION(ninf, vars)` constraint forces the number of inflexions of the sequence of variables `vars` to be equal to the variable `ninf`. An inflexion is described by one of the following patterns: a strict increase followed by a strict decrease or, conversely, a strict decrease followed by a strict increase. For example, `INPLEXION(4, ⟨3, 3, 1, 4, 5, 5, 6, 5, 5, 6, 3⟩)` holds since we can extract from
the sequence 3314556563 the four subsequences 314, 565, 6556 and 563, which all follow one of these two patterns.

• The \texttt{ALLDIFFERENT}(\texttt{vars}) constraint forces all pairs of distinct variables of the collection \texttt{vars} to take distinct values. For example, \texttt{ALLDIFFERENT}([6, 1, 5, 9]) holds since we have four distinct values.

Parts (A1), (B1), (C1), (D1) and (E1) of Figure 2.11 depict the five checkers respectively associated with \texttt{GLOBAL\_CONTIGUITY}, with \texttt{LEX\_LESSEQ}, with \texttt{AMONG}, with \texttt{INFLexion} and with \texttt{ALLDIFFERENT}. Within the corresponding automata an initial state is indicated by an arc coming from no state and an accepting state is denoted graphically by a double circle. For each checker we note the following facts:

• Within the checker depicted by part (A1) of Figure 2.11, the values of the sequence \texttt{vars}[0], \ldots, \texttt{vars}[n-1] are successively compared against 0 and 1 in order to check that we have at most one group of consecutive 1. This can be translated to the automaton depicted by part (A2) of Figure 2.11. The automaton takes as input the sequence \texttt{vars}[0], \ldots, \texttt{vars}[n-1], and triggers successively a transition for each term of this sequence. Transitions labelled by 0 and 1 are respectively associated with the conditions \texttt{vars}[i] = 0 and \texttt{vars}[i] = 1. Transitions leading to failure are systematically skipped. This is why no transition labelled with a 1 starts from state \( z \).

• Within the checker given by part (B1) of Figure 2.11, the components of vectors \( \overrightarrow{x} \) and \( \overrightarrow{y} \) are scanned in parallel. We first skip all the components that are equal and then perform a final check. This is represented by the automaton depicted by part (B2) of Figure 2.11. The automaton takes as input the sequence \( \langle x[0], y[0] \rangle, \ldots, \langle x[n-1], y[n-1] \rangle \) and triggers a transition for each term of this sequence. Unlike the \texttt{GLOBAL\_CONTIGUITY} constraint, some transitions now correspond to a condition (e.g., \( x[i] = y[i], x[i] < y[i] \)) between two variables of the \texttt{LEX\_LESSEQ} constraint.

• Note that the \texttt{AMONG}(\texttt{nvar}, \texttt{vars}, \texttt{values}) constraint involves a variable \texttt{nvar} whose value is computed from a given collection of variables \texttt{vars}. The checker depicted by part (C1) of Figure 2.11 counts the number of variables of \texttt{vars}[0], \ldots, \texttt{vars}[n-1] that take their values in \texttt{values}. For this purpose it uses a counter \( c \), which is possibly tested against the value of \texttt{nvar}. This convinced us to allow the use of counters in an automaton. Each counter has an initial value, which can be updated while triggering certain transitions. The accepting states of an automaton can force a variable of the constraint to be equal to a given counter. Part (C2) of Figure 2.11 describes the automaton corresponding to the code given in part (C1) of the same figure. The automaton uses the counter variable \( c \) initially set to 0 and takes as input the sequence \texttt{vars}[0], \ldots, \texttt{vars}[n-1]. It triggers a transition for each variable of this sequence and increments \( c \) when the corresponding variable takes its value in \texttt{values}. The accepting state returns a success when the value of \( c \) is equal to \texttt{nvar}. At this point we want to stress the following fact: it would have been
possible to use an automaton that avoids the use of counters. However, this automaton would depend on the effective value of the argument nvar. In addition, it would require more states than the automaton of part (C2) of Figure 2.11. This is typically a problem if we want to have a fixed number of states in order to save memory as well as time.
As the AMONG constraint, the INFLEXION \((\text{ninf}, \text{vars})\) constraint involves a variable \text{ninf} whose value is computed from a given sequence of variables \(\text{vars}[0], \ldots, \text{vars}[n-1]\). Therefore, the checker depicted in part (D1) of Figure 2.11 uses also a counter \(c\) for counting the number of inflexions, and compares its final value to the \text{ninf} argument. The automaton depicted by part (D2) of Figure 2.11 represents this program. It takes as input the sequence of pairs \(\langle \text{vars}[0], \text{vars}[1] \rangle, \langle \text{vars}[1], \text{vars}[2] \rangle, \ldots, \langle \text{vars}[n-2], \text{vars}[n-1] \rangle\) and triggers a transition for each pair. Note that a given variable may occur in more than one pair. Each transition compares the respective values of two consecutive variables of \(\text{vars}[0..n-1]\) and increments the counter \(c\) when a new inflexion is detected. The accepting state returns a success when the value of \(c\) is equal to \text{ninf}.

The checker associated with ALLDIFFERENT is depicted by part (E1) of Figure 2.11. It first initialises an array of counters to 0. The entries of the array correspond to the potential values of the sequence \(\text{vars}[0], \ldots, \text{vars}[n-1]\). In a second phase the checker computes for each potential value its number of occurrences in the sequence \(\text{vars}[0], \ldots, \text{vars}[n-1]\). This is done by scanning this sequence. Finally in a third phase the checker verifies that no value is used more than once. These three phases are represented by the automaton depicted by part (E2) of Figure 2.11. The automaton depicted by part (E2) takes as input the sequence \(\text{vars}[0], \ldots, \text{vars}[n-1]\). Its initial state initialises an array of counters to 0. Then it triggers successively a transition for each element \(\text{vars}[i]\) of the input sequence and increments by 1 the entry corresponding to \(\text{vars}[i]\). The accepting state checks that all entries of the array of counters are strictly less than 2, which means that no value occurs more than once in the sequence \(\text{vars}[0], \ldots, \text{vars}[n-1]\).

Synthesising all the observations we got from these examples leads to the following remarks and definitions for a given global constraint \(C\):

- For a given state, no transition can be triggered indicates that the constraint \(C\) does not hold.

- Since all transitions starting from a given state are mutually incompatible all automata are deterministic. Let \(\mathcal{M}\) denotes the set of mutually incompatible conditions associated with the different transitions of an automaton.

- Let \(S_0, \ldots, S_{m-1}\) denotes the sequence of subsets of variables of \(C\) on which the transitions are successively triggered. All these subsets contain the same number of elements and refer to some variables of \(C\). Since these subsets typically depend on the constraint, we leave the computation of \(S_0, \ldots, S_{m-1}\) outside the automaton. To each subset \(S_i\) of this sequence corresponds a variable \(S_i\) with an initial domain ranging over \([\text{min}, \text{min} + |\mathcal{M}| - 1]\), where \(\text{min}\) is a fixed integer. To each integer of this range corresponds one of the mutually incompatible conditions of \(\mathcal{M}\). The sequences \(S_0, \ldots, S_{m-1}\) and \(S_0, \ldots, S_{m-1}\) are respectively called the signature and the signature argument of the constraint. The
constraint between $S_i$ and the variables of $S_i$ is called the *signature constraint* and is denoted by $\Psi_C(S_i, S_i)$.

- From a pragmatic point of view, the task of writing a constraint checker is naturally done by writing down an imperative program where local variables, arrays, assignment statements and control structures are used. This suggested us to consider deterministic finite automata augmented with local variables and assignment statements on these variables. Regarding control structures, we did not introduce any extra feature since the deterministic choice of which transition to trigger next seemed to be good enough.

- Many global constraints involve a variable whose value is computed from a given collection of variables. This convinced us to allow the accepting state of an automaton to optionally return a result. In practice, this result corresponds to the value of a local variable of the automaton in the accepting state.

### 2.4.2 Defining an automaton

An automaton $A$ of a global constraint $C$ is defined by

$$
\langle \text{Signature}, \text{SignatureDomain}, \text{SignatureArg}, \text{SignatureArgPattern}, \\
\text{Counters}, \text{Arrays}, \text{States}, \text{Transitions} \rangle
$$

where:

- *Signature* is the sequence of variables $S_0, \ldots, S_{m-1}$ corresponding to the signature of the constraint $C$.

- *SignatureDomain* is an interval that defines the range of possible values of the variables of Signature.

- *SignatureArg* is the signature argument $S_0, \ldots, S_{m-1}$ of the constraint $C$. The link between the variables of $S_i$ and the variable $S_i$ ($0 \leq i < m$) is done by writing down the signature constraint $\Psi_C(S_i, S_i)$.

- When used, *SignatureArgPattern* defines a symbolic name for each term of SignatureArg. These names can be used within the description of a transition for expressing an additional condition for triggering the corresponding transition.

- *Counters* is the, possibly empty, list of all counters used in the automaton $A$. Each counter is described by a term $t(\text{Counter}, \text{InitialValue}, \text{FinalVariable})$ where Counter is a symbolic name representing the counter, InitialValue is an integer giving the value of the counter in the initial state of $A$, and FinalVariable gives the variable that should be unified with the value of the counter in the accepting state of $A$.

- *Arrays* is the, possibly empty, list of all arrays used in the automaton $A$. Each array is described by a term $t(\text{Array}, \text{InitialValue}, \text{FinalConstraint})$.
where \textit{Array} is a symbolic name representing the array, \textit{InitialValue} is an integer giving the value of all the entries of the array in the initial state of \(\mathcal{A}\). \textit{FinalConstraint} denotes an existing constraint of the catalogue that should hold in the accepting state of \(\mathcal{A}\). Arguments of this constraint correspond to collections of variables that are bound to array of counters, or to variables that are bound to counters declared in \textit{Counters}. For an array of counters we only consider those entries that are located between the first and the last entries that were modified while triggering a transition of \(\mathcal{A}\).

- \textit{States} is the list of states of \(\mathcal{A}\), where each state has the form \textit{source}(\textit{id}), \textit{sink}(\textit{id}) or \textit{node}(\textit{id}). \textit{id} is a unique identifier associated with each state. Finally, \textit{source}(\textit{id}) and \textit{sink}(\textit{id}) respectively denote the initial and the accepting state of \(\mathcal{A}\). An automaton has a single initial state and at least one accepting state. The initial and accepting states may coincide.

- \textit{Transitions} is the list of transitions of \(\mathcal{A}\). Each transition \(t\) has the form \textit{arc}(\textit{id}_1, \textit{label}, \textit{id}_2) or \textit{arc}(\textit{id}_1, \textit{label}, \textit{id}_2, \textit{counters}). \textit{id}_1 and \textit{id}_2 respectively correspond to the state just before and just after \(t\), while \textit{label} denotes the value that the signature variable should have in order to trigger \(t\). When used, \textit{counters} gives for each counter of \textit{Counters} its value after firing the corresponding transition. This value is specified by an arithmetic expression involving counters, constants, as well as usual arithmetic functions, such as \(+, -, \text{min}, \text{or max}\). The order used in the \textit{counters} list is identical to the order used in \textit{Counters}.

**EXAMPLE:** As an illustrative example we give the description of the automaton associated with the \texttt{INPLEXION}(\textit{ninf}, \textit{vars}) constraint. We have:

- \textit{Signature} = \(S_0, S_1, \ldots, S_{n-2}\),
- \textit{SignatureDomain} = \([0..2]\),
- \textit{SignatureArg} = \langle \textit{vars}[0], \textit{vars}[1]\rangle, \ldots, \langle \textit{vars}[n-2], \textit{vars}[n-1]\rangle,
- \textit{SignatureArgPattern} is not used,
- \textit{Counters} = \texttt{t(c, 0, \textit{ninf})},
- \textit{States} = \texttt{[source(s), sink(s), sink(i), sink(j)]},
- \textit{Transitions} = \{ \texttt{arc(1, s, 2, i)}, \texttt{arc(2, s, 0, j)}, \texttt{arc(i, 1, i)}, \texttt{arc(i, 2, i)}, \texttt{arc(i, 0, j, [i+1])}, \texttt{arc(j, 1, j)}, \texttt{arc(j, 0, j)}, \texttt{arc(j, 2, i, [i+1])}\}.

The signature constraint relating each pair of variables \(\langle \textit{vars}[i], \textit{vars}[i+1]\rangle\) to the signature variable \(S_i\) is defined as follows: \(\Psi_{\text{inflexion}}(S_i, \textit{vars}[i], \textit{vars}[i+1]) \equiv \text{vars}[i] > \text{vars}[i+1] \iff S_i = 0 \land \text{vars}[i] = \text{vars}[i+1] \iff S_i = 1 \land \text{vars}[i] < \text{vars}[i+1] \iff S_i = 2\). The sequence of transitions triggered on the ground instance \texttt{INPLEXION}(4, \texttt{[3, 3, 1, 4, 5, 5, 6, 5, 6, 3]}\) is \(\text{\begin{array}{lllllllll} j & 1 < 4 & S_2 = 2 & j & 4 < 5 & S_3 = 2 & i & 5 < 5 & S_4 = 1 & j & 5 < 6 & S_5 = 2 & i & 6 > 5 & S_6 = 0 & j \\ c = 1 & c = 2 & c = 3 & c = 4 & c = 2 & c = 2 & c = 3 & c = 4 & c = 2 & c = 2 \end{array}}\). Each transition gives the corresponding condition and, possibly, the value of the counter \(c\) just after firing that transition. After the last encountered state \(j\) the first argument \textit{ninf} of the \texttt{INPLEXION} constraint is fixed to the current value of the counter \(c\), i.e. \textit{ninf} = 4.
2. DESCRIBING GLOBAL CONSTRAINTS

2.5 Reformulating global constraints as a conjunction

Many global constraints can be reformulated as a conjunction of global or reified constraints. The slot Reformulation provides for some global constraints such reformulations (see, for example, the reformulation slots respectively associated with the COLOURED, CUMULATIVE or the TREE constraints). When it exists, the corresponding code is available in the “.pl file” attached to a constraint. The initial concrete motivation for providing reformulations was triggered by the fact that it is usually an easy way to have a first implementation of a constraint, which is a feature we want to have in the context of the catalogue. However many reformulations (e.g., ALLDIFFERENT, NVALUE, TREE) involve a quadratic (or even more) number of variables and/or constraints, which does not scale in practice when one wants to handle constraints with thousands of variables. This is why many filtering algorithms compute again and again common quantities that would require too much memory if stored explicitly.

2.6 Semantic links between global constraints

For each global constraint entry of the catalogue, the slot See also provides links to other global constraints. Rather than just pointing to a set of constraints, we prefer to explicitly indicate the reason why we point to a given constraint. A link \( \text{link}(C_{entry}, C_{also}) \) from a constraint \( C_{entry} \) (i.e., the constraint associated with a catalogue entry) to another constraint \( C_{also} \) (i.e., the constraint of the See also slot located in the catalogue entry of constraint \( C_{entry} \)) has a given semantics and this section describes the kind of semantic links that are currently used. Before introducing each semantic link and its meaning, let us first quote that some of them are related by one of the following relations:

- A link \( \text{link} \) is symmetric if and only if \( \text{link}(C_1, C_2) \Leftrightarrow \text{link}(C_2, C_1) \).
- A link \( \text{link} \) is asymmetric if and only if \( \text{link}(C_1, C_2) \Rightarrow \neg \text{link}(C_2, C_1) \) (\( \neg \text{link}(C_2, C_1) \) is a shortcut for denoting that the link \( \text{link}(C_2, C_1) \) does not occur in the catalogue).
- A link \( \text{link}_j \) is the converse of a link \( \text{link}_i \) if and only if \( \text{link}_i(C_1, C_2) \Leftrightarrow \text{link}_j(C_2, C_1) \).

Table 2.1 lists each semantic link and the relation it has.\(^{32}\) Then one section describes the meaning of each semantic link.

2.6.1 Assignment dimension added

Constraint \( C_{also} \) corresponds to constraint \( C_{entry} \) where an assignment dimension is added to \( C_{entry} \).

\(^{32}\)All links are automatically checked with respect to their relations each time the catalogue is generated.

Table 2.1: Available semantic links between constraints

**EXAMPLE:** As an example, constraint $C_{also} = \text{CUMULATIVES}$ corresponds to constraint $C_{entry} = \text{CUMULATIVE}$ where an assignment dimension corresponding to the machine attribute is added (i.e., the constraint \text{CUMULATIVES} enforces a \text{CUMULATIVE} constraint for each maximum set of tasks that are assigned the same machine).

#### 2.6.2 Assignment dimension removed

Constraint $C_{also}$ corresponds to constraint $C_{entry}$ where an assignment dimension is removed from $C_{entry}$.

**EXAMPLE:** As an example, constraint $C_{also} = \text{AMONG_LOW_UP}$ corresponds to constraint $C_{entry} = \text{INTERVAL_AND_COUNT}$ where an assignment dimension corresponding to the origin attribute is removed from $C_{entry} = \text{INTERVAL_AND_COUNT}$ (i.e., the constraint \text{INTERVAL_AND_COUNT} enforces a \text{AMONG_LOW_UP} constraint for each maximum set of tasks for which the origin is assigned the same interval $[k \cdot \text{SIZE_INTERVAL}, k \cdot \text{SIZE_INTERVAL} + \text{SIZE_INTERVAL} - 1]$) ($\text{SIZE_INTERVAL}$ is the last argument of \text{INTERVAL_AND_COUNT}).
2.6.3 Attached to cost variant

Constraint $C_{also}$ is the original version attached to the cost variant constraint $C_{entry}$.

**EXAMPLE:** As an example, constraint $C_{also} = \text{ALLDIFFERENT}$ is the original version attached to the cost variant constraint $C_{entry} = \text{MINIMUM_WEIGHT_ALLDIFFERENT}$, where the total cost of a solution is the sum of the costs associated with the fact that we assign a given value to a specific variable.

2.6.4 Common keyword

Constraints $C_{entry}$ and $C_{also}$ share one or more common keywords with a strong semantic connotation.

**EXAMPLE:** As an example, constraints $C_{entry} = \text{TREE}$ and $C_{also} = \text{CYCLE}$ are both graph partitioning constraints (i.e., constraints that partition the vertices of a given initial digraph so that each partition corresponds to a specific pattern, a tree and a circuit in this example).

2.6.5 Comparison swapped

Constraint $C_{also}$ corresponds to constraint $C_{entry}$ where one of the following conditions holds:

- The comparison operator $\geq$ is swapped to $\leq$, or conversely, $\leq$ is swapped to $\geq$.
- The comparison operator $>$ is swapped to $<$, or conversely, $<$ is swapped to $>$.

**EXAMPLE:** Constraint $C_{also} = \text{ATMOST}$ corresponds to constraint $C_{entry} = \text{ATLEAST}$ where the comparison $\leq n$ for expressing that we should not exceed a given threshold (i.e., restricts the maximum number of occurrences for a given value) is replaced by $\geq n$ for expressing that we should reach a given threshold (i.e., forces a minimum number of occurrences for a given value).

2.6.6 Cost variant

Constraint $C_{also}$ is a cost variant of constraint $C_{entry}$.

**EXAMPLE:** As an example, constraint $C_{also} = \text{SUM_OF_WEIGHTS_OF_DISTINCT_VALUES}$ is the cost variant of constraint $C_{entry} = \text{NVALUE}$, where we introduce a weight for each value and we replace the number of distinct values by the sum of weights associated with distinct values.

2.6.7 Generalisation

Denotes that constraint $C_{also}$ is a generalisation of constraint $C_{entry}$.

**EXAMPLE:** As an example, constraint $C_{also} = \text{ALL_MIN_DIST}$ is a generalisation of constraint $C_{entry} = \text{ALLDIFFERENT}$ where we replace a disequality between two variables by the fact that two line segments of same length do not overlap.
2.6.8 Hard version

Constraint $C_{also}$ is a hard version of constraint $C_{entry}$ (i.e., constraint $C_{entry}$ is a soft variant of constraint $C_{also}$).

**EXAMPLE:** As an example, constraint $C_{also} = \textsc{ALLDIFFERENT}$ is a hard version of constraint $C_{entry} = \textsc{SOFT,ALLDIFFERENT}$, which restricts the minimum number of variables that should be assigned differently in order that all variables take a distinct value.

2.6.9 Implied by

If constraint $C_{also}$ holds and if all restrictions of constraint $C_{entry}$ hold then constraint $C_{entry}$ also holds. Note that we try to restrict ourselves to the transitive reduction of the implication graph between constraints.

**EXAMPLE:** As an example, constraint $C_{entry} = \textsc{MINIMUM}$ is implied by constraint $C_{also} = \textsc{AND}$.

2.6.10 Implies

If constraint $C_{entry}$ holds and if all restrictions of constraint $C_{also}$ hold then constraint $C_{also}$ also holds. Note that we also consider all the implications depicted in the implication graphs mentioned in the tables associated with the normalised signature tree of global constraints arguments. For an example of such table see Table 3.1.

**EXAMPLE:** As an example, constraint $C_{entry} = \textsc{ALLDIFFERENT}$ implies constraint $C_{also} = \textsc{NOT\_ALL\_EQUAL}$. Note that the case of an $\textsc{ALLDIFFERENT}$ constraint with a single variable does not imply a $\textsc{NOT\_ALL\_EQUAL}$ constraint since its restriction (i.e., the number of variables of a $\textsc{NOT\_ALL\_EQUAL}$ constraint should be strictly greater than one) does not hold.

2.6.11 Implies (if swap arguments)

Given two constraints $C_{entry}$ and $C_{also}$ that both have two arguments, if constraint $C_{entry}(\text{arg}_1, \text{arg}_2)$ holds then constraint $C_{also}(\text{arg}_2, \text{arg}_1)$ also holds.

**EXAMPLE:** As an example, we can go from constraint $C_{entry} = \textsc{LEX\_LESSEQ}$ to constraint $\textsc{LEX\_GREATEREQ}$ if we swap the two arguments of constraint $\textsc{LEX\_LESSEQ}$.

2.6.12 Implies (items to collection)

Given two constraints $C_{entry}$ and $C_{also}$ where:

- $C_{entry}$ has a single argument $\text{arg}_1$ corresponding to a collection of $k$ items, each attribute of type int or dvar.

- $C_{also}$ has a single argument $\text{arg}_2$ corresponding to a collection of collections of dvar, each of them having the same number of items $k$.

If constraint $C_{entry}(\text{arg}_1)$ holds then constraint $C_{also}(\text{arg}_2)$ also holds.
2.6.13 Negation

If constraint $C_{entry}$ holds then constraint $C_{also}$ does not hold. Reciprocally, if constraint $C_{also}$ holds then constraint $C_{entry}$ does not hold. Note that constraints $C_{entry}$ and $C_{also}$ must also have exactly the same parameters, but not necessarily the same parameters restrictions.

**EXAMPLE:** As an example, the constraint $C_{also} = \text{NOT\_ALL\_EQUAL}$ (i.e., prevent all variables to be assigned the same value) is the negation of constraint $C_{entry} = \text{ALL\_EQUAL}$ (i.e., enforce all variables to be assigned the same value).

Note that negation is also directly available for constraints which are defined by:

- A single counter free automaton, see keyword automaton without counters.
- A single automaton with counter, see keyword automaton with counters.
- A set of functional dependencies, see keyword pure functional dependency.

2.6.14 Part of system of constraints

Denotes that a constraint $C_{entry}$ is a conjunction of constraints $C_{also}$ (i.e., see the keyword system of constraints).

**EXAMPLE:** As an example, the constraint $C_{also} = \text{NEQ}$ (i.e., prevent two variables to be assigned the same value) can be used to reformulate the constraint $C_{entry} = \text{ALLDIFFERENT}$ (i.e., enforce a set of variables to take distinct values) as a conjunction of $\text{NEQ}$ constraints.

2.6.15 Related

Denotes that a constraint $C_{entry}$ and a constraint $C_{also}$ are related by a specific reason that is not covered by an existing link.

**EXAMPLE:** As an example, the constraint $C_{also} = \text{TREE\_RANGE}$ (i.e., given a digraph, partition it so that each vertex belongs to one tree for which the difference between the longest and the shortest paths – from a leaf to the root – is restricted) is related to the constraint $C_{entry} = \text{BALANCE}$ (i.e., given a set of variables, restrict the difference between the number of occurrence of the value that occurs the most and the value that occurs the least) by the fact that, on the one hand the constraint $\text{TREE\_RANGE}$ can express a balanced tree, on the other side the constraint $\text{BALANCE}$ can express a balanced assignment.

2.6.16 Related to a common problem

Denotes that a constraint $C_{entry}$ and a constraint $C_{also}$ are related to a same problem (i.e., they can both be used for modelling that problem).
2.6. SEMANTIC LINKS BETWEEN GLOBAL CONSTRAINTS

EXAMPLE: As an example, the constraints \( C_{\text{entry}} = \text{COLORED\_MATRIX} \) and \( C_{\text{also}} = \text{SAME} \) can both be used for modelling the matrix reconstruction problem.

2.6.17 Root concept

Constraint \( C_{\text{entry}} \) is derived from constraint \( C_{\text{also}} \).

EXAMPLE: As an example, the constraint \( C_{\text{entry}} = \text{TREE\_RESOURCE} \) is derived from the constraint \( C_{\text{also}} = \text{TREE} \). Given a digraph \( G \), the \( \text{TREE} \) constraint forces a partitioning of \( G \) by a set of trees in such a way that each vertex of \( G \) belongs to one distinct tree. In addition, the \( \text{TREE\_RESOURCE} \) constraint distinguishes resource and task vertices, and forces each tree to contain exactly one resource vertex.

2.6.18 Shift of concept

Constraint \( C_{\text{also}} \) is derived from constraint \( C_{\text{entry}} \).

EXAMPLE: As an example, constraint \( C_{\text{also}} = \text{GLOBAL\_CARDINALITY\_NO\_LOOP} \) is derived from constraint \( C_{\text{entry}} = \text{GLOBAL\_CARDINALITY} \) (i.e., each value \( \text{VALUES}[i].\text{val} \) should be taken by exactly \( \text{VALUES}[i].\text{val} \) variables of the \( \text{VARIABLES} \) collection) by discarding all variables such that \( \text{VARIABLES}[i].\text{var} = i \).

2.6.19 Soft variant

Constraint \( C_{\text{also}} \) is a soft variant of constraint \( C_{\text{entry}} \). Note that, from an academic point of view, a soft constraint \( C_{\text{also}} \) is usually defined with a cost variable that quantifies how much the constraint \( C_{\text{entry}} \) is violated. We exceptionally breaks this rule when it seems to make sense from an application point of view. For example, within the \( \text{ALLDIFFERENT} \) constraint, we refer to the \( \text{ALLDIFFERENT\_EXCEPT} \) since it can be seen as a kind of relaxation of the \( \text{ALLDIFFERENT} \) constraint where we allow to use value 0 several times.

EXAMPLE: As an example, one of the possible soft variants of constraint \( C_{\text{entry}} = \text{ALLDIFFERENT} \) (i.e., the \( \text{ALLDIFFERENT} \) constraint forces all variables of a collection to take distinct values) is the constraint \( C_{\text{also}} = \text{SOFT\_ALLDIFFERENT\_VAR} \), where the cost is the minimum number of variables that need to be assigned differently to satisfy the \( \text{ALLDIFFERENT} \) constraint.

2.6.20 Specialisation

Denotes that constraint \( C_{\text{also}} \) is a specialisation of constraint \( C_{\text{entry}} \).

EXAMPLE: As an example, constraint \( C_{\text{also}} = \text{PATH} \) is a specialisation of constraint \( C_{\text{entry}} = \text{TREE} \). Given a digraph \( G \), the \( \text{TREE} \) constraint forces a covering of \( G \) by a set of trees in such a way that each vertex of \( G \) belongs to one distinct tree. If, in addition, we restrict each vertex to have at most one child we get the \( \text{PATH} \) constraint.
2.6.21 System of constraints

Denotes that a constraint $C_{also}$ is a conjunction of constraints $C_{entry}$ (see the keyword system of constraints).

**EXAMPLE:** As an example, the constraint $C_{also} = \text{COLORED\_MATRIX}$ corresponds to a conjunction of constraints of the form $C_{entry} = \text{GLOBAL\_CARDINALITY}$. Given a matrix $M$ of variables, the \text{COLORED\_MATRIX} constraint forces a \text{GLOBAL\_CARDINALITY} on each row and each column of $M$.

2.6.22 Used in graph description

Constraint $C_{also}$ is used within a graph based description of constraint $C_{entry}$.

**EXAMPLE:** As an example, the constraint $C_{also} = \text{TWO\_ORTH\_DO\_NOT\_OVERLAP}$, a constraint enforcing two orthotopes to not overlap, is used in the graph based description of the constraint $C_{entry} = \text{DIFFN}$. Given a collection of orthotopes, the \text{DIFFN} constraint forces for each pair of orthotopes $(O_1, O_2)$ that $O_1$ and $O_2$ do not overlap.

*A orthotope corresponds to the generalisation of a segment, a rectangle and a box to the n-dimensional case.*

2.6.23 Used in reformulation

Constraint $C_{also}$ is used within a reformulation of constraint $C_{entry}$. Since it is already handled by the link part of system of constraints, we do not consider the case where constraint $C_{entry}$ can be expressed as a conjunction of constraints $C_{also}$.

**EXAMPLE:** As an example, the constraint $C_{also} = \text{OPEN\_MINIMUM}$ is used within the reformulation slot of the constraint $C_{entry} = \text{TREE\_RANGE}$.

2.6.24 Uses in its reformulation

Constraint $C_{also}$ uses constraint $C_{entry}$ in its reformulation. Since it is already handled by the link system of constraints, we do not consider the case where constraint $C_{also}$ can be expressed as a conjunction of constraints $C_{entry}$.

**EXAMPLE:** As an example, the reformulation slot of constraint $C_{also} = \text{TREE\_RANGE}$ uses the constraint $C_{entry} = \text{OPEN\_MINIMUM}$.

3. DESCRIPTION OF THE CATALOGUE

3.1 Which global constraints are included?

The global constraints of this catalogue come from the following sources:

- Existing constraint systems like:
  - ALICE [267],

---

3.7.245 Statistics ........................................ 375
3.7.246 Strip packing .................................... 375
3.7.247 Strong articulation point ....................... 375

3.7.276 Weighted assignment .............................. 399
3.7.277 Workload covering ............................... 399
3.7.278 Zebra puzzle ..................................... 400
3.7.279 Zero-duration task ............................... 405
3.1. WHICH GLOBAL CONSTRAINTS ARE INCLUDED?

- CHARME in C [309],
- CHIP [150] in Prolog, C and C++ (http://www.cosytec.com),
- Choco [256] in Java (http://choco.emn.fr/),
- ECLAIR [416] in Claire,
- ECLiPSe [121, 11] in Prolog (http://eclipseclp.org/),
- FaCile in OCaml (http://www.recherche.enac.fr/opti/facile/),
- Gecode in C++ [385] (http://www.gecode.org/),
- IF/PROLOG in Prolog (http://www.ifcomputer.com/IFProlog/Constraints/home_en.html),
- Ilog Solver [334] in C++ and later in Java (http://www.ilog.com),
- JaCoP in Java (http://www.jacop.eu/),
- Koolog in Java,
- Minion [199] (http://minion.sourceforge.net/index.html),
- Mozart [405, 130] in Oz (http://www.mozart-oz.org/),
- SICStus [109] in Prolog (http://www.sics.se/sicstus/).

When available, the Systems slot of a global constraint entry of the catalogue provides the name of the corresponding global constraint in the context of the Choco, Gecode, JaCoP, MiniZinc, and SICStus systems.

- Constraint programming articles mostly from conferences like:

  - The Principles and Practice of Constraint Programming (CP) (http://www.informatik.uni-trier.de/~ley/db/conf/cp/index.html),
  - The International Joint Conference on Artificial Intelligence (IJCAI) (http://www.informatik.uni-trier.de/~ley/db/conf/ijcai/index.html),
  - The National Conference on Artificial Intelligence (AAAI) (http://www.informatik.uni-trier.de/~ley/db/conf/aaai/index.html),
  - The International Conference on Logic Programming (ICLP) (http://www.informatik.uni-trier.de/~ley/db/conf/iclp/index.html),
  - The International Conference of AI and OR Techniques in Constraint Programming for Combinatorial Optimisation Problems (CPAIOR) (http://www.informatik.uni-trier.de/~ley/db/conf/cpaior/).

- Graph constraints from the CP(Graph) computation domain [151].

- New constraints inspired by variations of existing constraints, practical applications, combinatorial problems, puzzles or discussions with colleagues.
3.2 Which global constraints are missing?

Constraints with too many arguments like, for example, the original \textsc{cycle} \cite{133} constraint with 16 arguments, which are in fact a combination of several constraints, were not directly put into the catalogue. Constraints that have complex arguments were also omitted. Beside this, the following constraints should be added in some future version of the catalogue: \textsc{alldifferent} on \textsc{multisets} \cite{346, 347}, \textsc{case} \cite{108, 103, 122, 123}, \textsc{choquet} \cite{231}, \textsc{cost\_regular} \cite{145}, \textsc{cumulative\_trapeze} \cite{331, 59}, \textsc{deviation} \cite{382, 380}, \textsc{inequality\_sum} \cite{365, 366}, \textsc{minimum\_spanning\_tree} \cite{152, 360}, \textsc{no\_cycle} \cite{113}, \textsc{range} \cite{69, 71}, \textsc{regular} \cite{317} \cite{134}, \textsc{soft\_gcc\_val} \cite{435, 436, 457, 383}, \textsc{soft\_gcc\_var} \cite{435, 436, 457}, \textsc{soft\_regular} \cite{435}, \textsc{spread} \cite{318, 381}, \textsc{multicost\_regular} \cite{293}, \textsc{pref\_alldifferent\_var} (i.e., variable-based relaxation of \textsc{alldifferent} with preferences) \cite[page 100]{295}, \textsc{pref\_alldifferent\_ctr} (i.e., decomposition-based relaxation of \textsc{alldifferent} with preferences) \cite[page 103]{295}, \textsc{pref\_global\_cardinality\_low\_up\_var} (i.e., variable-based relaxation of \textsc{global\_cardinality\_low\_up} with preferences) \cite[page 123]{295}, \textsc{pref\_global\_cardinality\_low\_up\_ctr} (i.e., decomposition-based relaxation of \textsc{global\_cardinality\_low\_up} with preferences) \cite[page 126]{295}. Finally we only consider a restricted number of constraints involving set variables since this is a relatively new area, which is currently growing rapidly since 2003.

3.3 Searching in the catalogue

3.3.1 How to see if a global constraint is in the catalogue?

Searching a given global constraint through the catalogue can be achieved in the following ways:

- If you have an idea of the name of the global constraint you are looking for, then put all its letters in lower case, separate distinct words by an underscore and search the resulting name in the index. Within the pdf document, the entry of the catalogue where the constraint is defined is shown in \textbf{bold}. Common abbreviations, synonyms and usual names found in articles have also been put in the index in \textit{bold and italic}.

- If you do not know the name of the global constraint you are looking for, but you know the types of its arguments then Section 3.5 lists the different argument patterns and the corresponding global constraints.

- You can also search a global constraint through the list of keywords that is attached to each global constraint. All available keywords are listed alphabetically in Section 3.7 on page 161. For each keyword we give the list of global constraints using the corresponding keyword as well as the definition of the keyword.
3.3. SEARCHING IN THE CATALOGUE

- In order to make it possible to search for all keywords related to a specific area, we have also attached to each keyword one, or exceptionally two, meta-keywords. For example, if you are searching for global constraints that are mentioning puzzles, you first look to the meta-keyword *Puzzles* where you find the keywords corresponding to puzzles (i.e., *Autoref*, *Conway packing problem*, ..., *Sudoku*, *Zebra puzzle*). Then as previously described, for each keyword you can access to the corresponding global constraints. All available meta-keywords are listed alphabetically in Section 3.6 on page 150. For each meta-keyword it first gives the list of keywords using the corresponding meta-keyword and then defines the meta-keyword.

3.3.2 How to search for all global constraints sharing the same structure

Since we have three ways of defining global constraints (e.g., searching for a graph with specific properties, coming up with an automaton that only recognises the solutions associated with the global constraint or using a first order logic formula) we can look to the global constraints from these three perspectives.

Searching from a graph property perspective

The index contains all the arc generators as well as all the graph properties and the pages where they are mentioned.\(^1\) This allows finding all global constraints that use a given arc generator or a given graph property in their definitions. You can further restrict your search to those global constraints using a specific combination of arc generators and graph properties. All these combinations are listed at the “signature” entry of the index. Within these combinations, a graph property with an underline means that the constraint should be evaluated each time the minimum of this graph property increases. Similarly a graph property with an overline indicates that the constraint should be evaluated each time the maximum of this graph property decreases. For example, if we look for those constraints that both use the *CLIQUE* arc generator as well as the *NARC* graph-property we find the *INVERSE* and *PLACE_IN_PYRAMID* constraints. Since *NARC* is underlined and overlined these constraints will have to be woken each time the minimum or the maximum of *NARC* changes. The signature associated with a global constraint is also shown in the header of the even pages corresponding to the description of the global constraint.

Searching from an automaton perspective

We have created the following list of keywords, which allow finding all global constraints defined by a specific type of automaton that recognises its solutions\(^2\):

- **Automaton** indicates that the catalogue provides a deterministic automaton,

---

\(^1\)Arc generators and graph properties are introduced in the section “Describing Explicitly Global Constraints”.

\(^2\)Automata that recognise the solutions to a global constraint were introduced in the section “Describing Explicitly Global Constraints”.
3. DESCRIPTION OF THE CATALOGUE

- **Automaton without counters** indicates that the catalogue provides a deterministic automaton without counters as well as without array of counters,

- **Automaton with counters** indicates that the catalogue provides a deterministic automaton with counters but without array of counters,

- **Automaton with array of counters** indicates that the catalogue provides a deterministic automaton with array of counters and possibly with counters.

In addition, we also provide a list of keywords that characterise the structure of the hypergraph associated with the decomposition of the automaton of a global constraints (i.e., see the meta-keyword constraint network structure). Note that, when a global constraint is defined by several graph properties it is also defined by several automata (usually one automata for each graph property). This is the case, for example, of the CHANGE_CONTINUITY constraint. Currently we have these keywords:

- Berge-acyclic constraint network,
- Alpha-acyclic constraint network(2),
- Alpha-acyclic constraint network(3),
- Sliding cyclic(1) constraint network(1),
- Sliding cyclic(1) constraint network(2),
- Sliding cyclic(1) constraint network(3),
- Sliding cyclic(2) constraint network(2),
- Circular sliding cyclic(1) constraint network(2),
- Centered cyclic(1) constraint network(1),
- Centered cyclic(2) constraint network(1),
- Centered cyclic(3) constraint network(1),

When a global constraint is only defined by one or several automaton its signature is set to the keyword AUTOMATON.

**Searching from a first order logic perspective**

The keyword logic provides the list of constraints that are described within the catalogue in term of a first order logic formula where predicates are replaced by arithmetic constraints.

**3.3.3 Searching all places where a global constraint is referenced**

Beside the page where a global constraint is defined (in bold), the index also gives all the pages where a global constraint is referenced.

Last, since a global constraint can also be used for defining another global constraint the slot **Used in** of the description of a global constraint provides this information.
3.3.4 Searching the mapping with a constraint of a concrete system

Two distinct ways are provided for making the correspondence between a constraint of the catalogue and a constraint of a concrete existing system:

1. Appendix C provides, when it exists, the direct correspondence\(^3\) between the constraints of the catalogue and the constraints of a given concrete system. For the time being we have considered, with the help of their respective authors, the following systems:
   - **Choco** in Java [256] (http://choco.emn.fr/),
   - **Gecode** in C++ [385] (http://www.gecode.org/),
   - **JaCoP** in Java (http://www.jacop.eu/),
   - **MiniZinc** (http://www.minizinc.org/),
   - **SICStus** [109] in Prolog (http://www.sics.se/sicstus/).

Since not all constraints of a given system always have their counterparts in the current version of the catalogue, and since systems are always enriched, this is the reason why this mapping is not complete.

2. Within the entry of the catalogue the slot **Systems** provides the correspondence between the constraint associated with that entry and the name of the constraint in a given concrete system or modelling language. For example, the **Systems** slot of the entry of the catalogue corresponding to the **ELEMENT** constraint indicates that **ELEMENT** is called **NTH** in **Choco** and **ELEMENT** in **Gecode**, **JaCoP**, **MiniZinc** and **SICStus**.

3.4 Figures of the catalogue

The catalogue contains the following types of figures:

- Figures that give the normalised signature tree of the arguments of a global constraint. These figures are located in Section 3.5.

- Figures that provide the implication graph between global constraints that have the same normalised signature tree for their arguments (e.g., see the figure embedded in the lower part of Table 3.1).

- Figures that illustrate a global constraint or a keyword (e.g., see Figure 3.38 that illustrates the keyword **limited discrepancy search**).

- Figures that depict the initial as well as the final graphs associated with a global constraint (e.g., see Figure 5.159 that provides the initial and final graphs of the **CHANGE** constraint).

\(^3\)We do not consider that a given constraint of the catalogue can be reformulated in terms of a conjunction of constraints of a given concrete system.
3. DESCRIPTION OF THE CATALOGUE

- Figures that provide an automaton that only recognises the solutions associated with a given global constraint (e.g., see Figure 5.387 that gives the automaton of the `GLOBAL_CONTIGUITY` constraint).

- Figures that give the hypergraph associated with the decomposition of an automaton in terms of signature and transition constraints (e.g., see Figure 5.388 that gives the hypergraph of the automaton-based reformulation of the `GLOBAL_CONTIGUITY` constraint).

- Figures for the graph structure of the XML schema of the parameters of a global constraint. They are only available in the on-line version of the catalogue.

- Figures for visualising different views (i.e., compulsory part and cumulative profile) of two-dimensional placement of constraints. These figures are only available in the on-line version of the catalogue. They are accessible from the table containing the squared squares problem instances.

Most of the graph figures that depict the initial and final graph of a global constraint of this catalogue as well as the graph structure of the XML schema of the parameters of a global constraint were automatically generated by using the open source graph drawing software Graphviz [193] available from AT&T. Since late 2012 TiKZ [415] is used for generating all new figures and for converting the old Xfig, PSTricks [447] and Graphviz figures so that all figures are done with TiKZ.

---

3.5 Constraints argument patterns

If you do not know the name of the global constraint you are looking for, but you know the types of its arguments this section allows to find out all global constraints which have similar arguments. For this purpose we associate to each global constraint of the catalogue a unique normalised signature tree derived from the types of its arguments. The purpose of this normalised signature tree is to get a concise normal form of the arguments of a global constraint that does not depend on the order in which these arguments are defined.

Figure 3.1: Illustrating steps (2), (3) and (4) for computing the normalised signature tree

The normalisation takes as input the slots Type(s) and Argument(s) of the description of a global constraint and computes the normalised signature tree in four steps:

1. The first step converts all types related to variables to their corresponding ground counterparts: the types dvar, svar, mvar and rvar are respectively transformed to int, sint, mint and real.

2. The second step builds a tree of types \( T \) by exploring the slot Argument(s) and by developing the compound data types possibly used. The root of this tree is the type atom and represents the name of the global constraint.

3. The third step normalises the tree of types \( T \) by first normalising each subtree of \( T \) and then by sorting the children of \( T \). We assume the following ordering:

   - ALLDIFFERENT
   - CHANGE
   - COUNT
   - CUMULATIVE
   - DIFFN
   - MINIMUM
   - SAME

   An informal rule used in the catalogue about the order of the arguments of a constraint is that we usually first mention a domain variable which represents a result computed from one or several collections that occur just after. Finally, eventual parameters are put as the last arguments of the constraint.

   See Section 2.2.4 for the description of these slots.
3. DESCRIPTION OF THE CATALOGUE

on the different types: \texttt{atom} \preceq \texttt{int} \preceq \texttt{sint} \preceq \texttt{mint} \preceq \texttt{real} \preceq \texttt{list} \preceq \texttt{collection}. Let $T_n$ denotes the normalised tree obtained at this third step.

4. Finally the last step tries to reduce the size of the normalised tree $T_n$ by identifying $k (k > 1)$ children of a vertex $v$ of $T_n$ for which the $k$ subtrees are identical. When such a configuration is identified the $k$ subtrees of $v$ are replaced by a single subtree and the integer $k$ is put as an exponent of $v$.

Table 3.1: Example of information associated with a normalised signature tree (within the signature tree col is a shortcut for collection)

The three rows of Figure 3.1 illustrate respectively the second, third and fourth steps for computing the normalised signature tree associated with the arguments of the constraints ALLDIFFERENT, CHANGE, COUNT, CUMULATIVE, DIFFN, MINIMUM and SAME.

The next sections provide for each possible constraints arity all existing normalised signature trees together with the corresponding list of global constraints of the cata-
logue. The leftmost part of an entry corresponds to a normalised signature tree, while the rightmost upper part gives the corresponding list of global constraints. Finally the rightmost lower part describes the dependency between the constraints of the list: there is an edge from a constraint $\text{ctr}_1$ to a constraint $\text{ctr}_2$ if and only if the fact that $\text{ctr}_1$ holds implies that $\text{ctr}_2$ also holds. For example, consider the constraints associated with the normalised signature tree corresponding to two collections of integers depicted by Table 3.1. There is an edge from 16 (i.e., \textsc{sort}) to 14 (i.e., \textsc{same}) since the fact that a \textsc{sort} constraint holds implies that a \textsc{same} constraint also holds.

3.6 Meta-keywords attached to the keywords

This section explains the meaning of the meta-keywords attached to the keywords of the catalogue. Keywords are usually associated with a single meta-keyword, except some that are linked to the meta-keyword modelling exercises and to one other meta-keyword like modelling or puzzles (e.g., see the keywords magic series or degree of diversity of a set of solutions). For each meta-keyword it first gives the list of keywords using the corresponding meta-keyword and then defines the meta-keyword. At present the following meta-keywords are in use.

3.6.1 Application area

- Air traffic management,
- Assignment,
- Bioinformatics,
- Configuration problem,
- Deadlock breaking,
- Floor planning problem,
- Frequency allocation problem,
- Phylogeny,
- Program verification,
- SLAM problem,
- Sport timetabling,
- Workload covering.

Denotes that a keyword is related to an application area.

3.6.2 Characteristic of a constraint

- All different,
- Automaton,
- Automaton with array of counters,
- Automaton with counters,
- Automaton with same input symbol,
- Automaton without counters,
- Coloured,
- Consecutive values,
3.6. META-KEYWORDS ATTACHED TO THE KEYWORDS

- Convex,
- Convex hull relaxation,
- Core,
- Cyclic,
- Derived collection,
- Difference,
- Disequality,
- Equality,
- Hypergraph,
- Joker value,
- Maximum,
- maxint,
- Minimum,
- Modulo,
- Non-deterministic automaton,
- Pair,
- Partition,
- Product,
- Range,
- Rank,
- Reified automaton constraint,
- Reified constraint,
- Sort,
- Sort based reformulation,
- Sum,
- Time window,
- Tuple,
- Undirected graph,
- Vector.

Denotes that a keyword is related to a characteristic of the description of a constraint.

3.6.3 Combinatorial object

- Involution,
- Latin square,
- Matching,
- Multiset,
- Path,
- Pentomino,
- Periodic,
- Permutation,
- Relation,
- Run of a permutation,
- Sequence.

Denotes that a keyword corresponds to a combinatorial object or to a characteristic of a combinatorial object.
3. DESCRIPTION OF THE CATALOGUE

3.6.4 Complexity

- 3-dimensional-matching,
- 3-SAT,
- Minimum hitting set cardinality,
- Rectangle clique partition,
- Sequencing with release times and deadlines,
- Set packing,
- Subset sum.

Denotes that a keyword corresponds to a problem used to recognise NP-hard problems attached to the feasibility of a constraint.

3.6.5 Constraint network structure

- Alpha-acyclic constraint network(2),
- Alpha-acyclic constraint network(3),
- Berge-acyclic constraint network,
- Centered cyclic(1) constraint network(1),
- Centered cyclic(2) constraint network(1),
- Centered cyclic(3) constraint network(1),
- Circular sliding cyclic(1) constraint network(2),
- Sliding cyclic(1) constraint network(1),
- Sliding cyclic(1) constraint network(2),
- Sliding cyclic(1) constraint network(3),
- Sliding cyclic(2) constraint network(2),
- Sliding cyclic(2) constraint network(3),

Denotes that a keyword designates a specific constraint network structure occurring repeatedly in several constraints.
3.6. META-KEYWORDS ATTACHED TO THE KEYWORDS

3.6.6 Constraint type

- Arithmetic constraint,
- Boolean constraint,
- Conditional constraint,
- Constraint on the intersection,
- Counting constraint,
- Data constraint,
- Decomposition,
- Decomposition-based violation measure,
- Extension,
- Graph constraint,
- Graph partitioning constraint,
- Logic,
- Open automaton constraint,
- Open constraint,
- Order constraint,
- Overlapping alldifferent,
- Predefined constraint,
- Proximity constraint,
- Relaxation,
- Resource constraint,
- Scheduling constraint,
- Sliding sequence constraint,
- Soft constraint,
- System of constraints,
- Temporal constraint,
- Timetabling constraint,
- Value constraint,
- Value partitioning constraint,
- Variable-based violation measure.

Denotes that a keyword designates a constraint category.

3.6.7 Constraint arguments

- Aggregate,
- Binary constraint,
- Business rules,
- Constraint between three collections of variables,
- Constraint between two collections of variables,
- Constraint involving set variables,
- Contractible,
- Extensible,
- Pure functional dependency,
- Reverse of a constraint,
- Ternary constraint,
- Unary constraint.

Denotes that a keyword provides an information about the arguments of a constraint.
3.6.8 Filtering

- Abstract interpretation,
- Arc-consistency,
- Bipartite matching,
- Bipartite matching in convex bipartite graphs,
- Border,
- Bound-consistency,
- Compulsory part,
- Constructive disjunction,
- Convex bipartite graph,
- Cost filtering constraint,
- Cumulative longest hole problems,
- DFS-bottleneck,
- Duplicated variables,
- Dynamic programming,
- Entailment,
- Flow,
- Glue matrix,
- Hall interval,
- Hungarian method for the assignment problem,
- Hybrid-consistency,
- Klee measure problem,
- Linear programming,
- Minimum cost flow,
- Minimum task duration,
- Phi-tree,
- Planarity test,
- Quadtree,
- SAT,
- Strong articulation point,
- Strong bridge,
- Sweep.

Denotes that a keyword is related to an existing or a potential filtering algorithm of a constraint or to an algorithm checking a ground instance of a constraint.

3.6.9 Final graph structure

- Acyclic,
- Apartition,
- Bipartite,
- Circuit,
- Connected component,
- Consecutive loops are connected,
- Directed acyclic graph,
- Equivalence,
- No cycle,
- No loop,
- One succ,
- Strongly connected component,
- Symmetric,
- Tree,
- Vpartition.

Denotes that a keyword describes the structure of the final graph associated with a constraint.
3.6. **META-KEYWORDS ATTACHED TO THE KEYWORDS**

3.6.10 **Geometry**

- Alignment,
- Contact,
- Geometrical constraint,
- Guillotine cut,
- Line segments intersection,
- Non-overlapping,
- Orthotope,
- Polygon,
- Positioning constraint,
- RCC8,
- Touch.

Denotes that a keyword is related to a geometrical constraint or to a geometrical object.

3.6.11 **Heuristics**

- Heuristics,
- Heuristics and Berge-acyclic constraint network,
- Heuristics and lexicographical ordering,
- Heuristics for two-dimensional rectangle placement problems,
- Labelling by increasing cost,
- Limited discrepancy search,
- Regret based heuristics,
- Regret based heuristics in matrix problems.

Denotes that a keyword is related to a search heuristic.
3. DESCRIPTION OF THE CATALOGUE

3.6.12 Miscellaneous

- Obscure.

Denotes that a keyword does not belong to any class.

3.6.13 Modelling

- Array constraint,
- Assigning and scheduling tasks that run in parallel,
- Assignment dimension,
- Assignment to the same set of values,
- At least,
- At most,
- Balanced assignment,
- Balanced tree,
- Boolean channel,
- Channelling constraint,
- Cluster,
- Cost matrix,
- Cycle,
- Degree of diversity of a set of solutions,
- Difference between pairs of variables,
- Disjunction,
- Domain channel,
- Domain definition,
- Dual model,
- Empty intersection,
- Equality between multisets,
- Excluded,
- Functional dependency,
- Included,
- Inclusion,
- Incompatible pairs of values,
- Interval,
3.6. META-KEYWORDS ATTACHED TO THE KEYWORDS

- Matrix,
- Matrix model,
- Maximum number of occurrences,
- Minimum number of occurrences,
- Multi-site employee scheduling with calendar constraints,
- Number of changes,
- Number of distinct equivalence classes,
- Number of distinct values,
- Permutation channel,
- Preferences,
- Relaxation dimension,
- Scalar product,
- Scheduling with machine choice, calendars and preemption,
- Sequence dependent set-up,
- Set channel,
- Shared table,
- Sparse functional dependency,
- Sparse table,
- Statistics,
- Table,
- Variable indexing,
- Variable subscript,
- Zero-duration task.

Denotes that a keyword is related to a modelling issue.

3.6.14 Modelling exercises

- Assigning and scheduling tasks that run in parallel: inspired by a modelling question on the Choco mailing list about an assignment and scheduling problem involving nurses and surgeons, use one GEOST constraint as well as inequalities for breaking symmetries with respect to groups of identical persons. The keyword relaxation dimension shows how to extend the previous model in order to take into account over-constrained assignment and scheduling problems.

- Assignment to the same set of values: inspired by a presentation of F. Hermenier about a task assignment problem where subtasks have to be assigned a same group of machines, use several ELEMENT constraints and a single resource constraint that has an assignment dimension (e.g., BIN_PACKING, CUMULATIVES, DIFFN, GEOST).
• Degree of diversity of a set of solutions: inspired by a discussion with E. Hebrard, how to find out 9 completely different solutions for the 10-queens problem, use the ALLDIFFERENT, the SOFT_ALLDIFFERENT_CTR and the LEX_CHAIN_LESS constraints.

• Logigramhe: inspired by an instance from [328, page 36], use a conjunction of CONSECUTIVE_GROUPS_OF_ONES constraints.

• Magic series: a special case of Autoref, use a single GLOBAL_CARDINALITY constraint.

• Metro: a model from H. Simonis, use only LEQ_CST constraints and propagation (i.e., no enumeration) for modelling the shortest path problem in a network.

• Multi-site employee scheduling with calendar constraints: a timetabling problem, inspired by H. Simonis, where tasks have to be assigned groups of employees located in different countries subject to different calendars, use resource constraints as well as the CALENDAR constraint.

• n-Amazons: an extension of the n-queens problem, use one ALLDIFFERENT constraint, two ALLDIFFERENT_CST constraints and three SMOOTH constraints.

• relaxation dimension: illustrate how to model over-constrained placement problems by introducing an extra dimension in the context of the DIFFN and the GEOST constraints.

• Scheduling with machine choice, calendars and preemption: a scheduling problem with crossable and non-crossable unavailability periods as well as resumable and non-resumable tasks, illustrate the use of two time coordinates systems within the same model, use precedence and resource constraints as well as the CALENDAR constraint.

• Sequence dependent set-up: a classical scheduling problem, use the SUM_CTR, ELEMENT and TEMPORAL_PATH constraints.

• Zebra puzzle: illustrate the duality of choice of what is a variable and what is a value in a constraint model as well as the difficulty of stating the constraints in one of the two models, use the ALLDIFFERENT, the ELEMENT – with variables in the table – and the INVERSE constraints.

Denotes that a keyword describes a constraint modelling exercise.
3.6. 

**META-KEYWORDS ATTACHED TO THE KEYWORDS**

3.6.15  **Problems**

- Channel routing,
- Demand profile,
- Domination,
- Facilities location problem,
- Graph colouring,
- Hamiltonian,
- Maximum clique,
- Minimum feedback vertex set,
- Pallet loading,
- Pattern sequencing,
- Pick-up delivery,
- Producer-consumer,
- Schur number,
- Strip packing,
- Two-dimensional orthogonal packing,
- Weighted assignment.

Denotes that a keyword is related to a problem from Operations Research.

3.6.16  **Puzzles**

- Autoref,
- Conway packing problem,
- Costas arrays,
- Dominating queens,
- Euler knight,
- Golomb ruler,
- Logigraphe,
- Magic hexagon,
- Magic series,
- Magic square,
- n-Amazons,
- n-queens,
- Packing almost squares,
- Partridge,
- Pentomino,
- Shikaku,
- Smallest rectangle area,
- Smallest square for packing consecutive dominoes,
- Smallest square for packing rectangles with distinct sizes,
- Squared squares,
• Sudoku,
• Zebra puzzle.

Denotes that a keyword is related to a specific puzzle.

3.6.17 Symmetry

• Indistinguishable values,
• Lexicographic order,
• Matrix symmetry,

• Multiset ordering,
• Symmetry,
• Value precedence.

Denotes that a keyword is related to a symmetry breaking technique [129, 180].
3.7 Keywords attached to the global constraints

This section explains the meaning of the keywords attached to the global constraints of the catalogue. For each keyword it first gives the list of global constraints using the corresponding keyword and then defines the keyword. At present the following keywords are in use.

3.7.1 3-dimensional-matching

Denotes that, by reduction to 3-dimensional-matching, deciding whether a constraint has a solution or not was shown to be NP-hard. The 3-dimensional-matching problem can be described as follows: given a set $S \subseteq X \times Y \times Z$, where $X$, $Y$ and $Z$ are disjoint sets having the same number of elements $m$, does $S$ contain a subset $M$ of $m$ elements such that no two elements of $M$ agree in any coordinate?

3.7.2 3-SAT

Denotes that, by reduction to 3-SAT, deciding whether a constraint has a solution or not was shown to be NP-hard. The 3-SAT problem can be described as follows: given a collection $C$ of clauses involving a set of variables $V$, where each clause has exactly 3 variables, is there a truth assignment for $V$ that satisfies all the clauses of $C$?
3. DESCRIPTION OF THE CATALOGUE

3.7.3 Abstract interpretation

- GCD,
- POWER.

Denotes that abstract interpretation was used for deriving a filtering algorithm for a constraint $C$ from a polynomial algorithm describing a checker for a ground instance of $C$. Abstract interpretation [136] executes an algorithm on abstract values in order to deduce some information about that algorithm.

3.7.4 Acyclic

- USED_BY_PARTITION (union, union, id),
- USES (union, union).

Denotes that, given two instances of a constraint, we can combine (i.e., aggregate) these two instances in order to obtain a third constraint, which has the same name as the first two constraints. The first two constraints are called the source constraints, while the implied constraint is called the target constraint. The ith argument of the target constraint is obtained by combining the ith arguments of the two source constraints. This is specified for each argument by one of the following options.

- id: check that the corresponding arguments of the two source constraints are identical and take it as the argument of the target constraint; this option if often used for specifying that an argument corresponding to a parameter has to be the same in the two source constraints, as well as in the target constraint (i.e., the source and the target constraints share the same parameter).

- +: add the corresponding arguments of the two source constraints.

- ∗: multiply the corresponding arguments of the two source constraints.

- ∧: make an and between the corresponding 0-1 arguments of the two source constraints.

- ∨: make an or between the corresponding 0-1 arguments of the two source constraints.
• min: take the minimum of the corresponding arguments of the two source constraints.

• max: take the maximum of the corresponding arguments of the two source constraints.

• union: take the union, without removing duplicates, of the collections items of the corresponding arguments of the two source constraints.

• sunion: take the union, and remove duplicates, of the collections items of the corresponding arguments of the two source constraints, where collections correspond to collection of ground values (i.e., parameters).

Finally, the aggregation may be conditioned by a list of restrictions, each restriction corresponding to one of the restrictions described in Section 2.2.3. We call this conditional aggregation.

Most constraints for which aggregation applies correspond to constraints where one of the arguments is functionally determined by the other arguments. For example, this is the case for the \texttt{MAXIMUM}(\texttt{MAX}, \texttt{VARIABLES}) constraint which forces \texttt{MAX} to be equal to the maximum value assigned to the variables of \texttt{VARIABLES}. However some constraints, like the \texttt{SAME} constraint, for which aggregation applies, do not have any argument that is functionally determined by the other arguments.

We now present three examples of deductions that can be obtained by aggregating two source constraints.

• \texttt{AMONG}(1, \langle 4, 5, 5, 4, 1 \rangle, \langle 0, 1 \rangle) \land \texttt{AMONG}(3, \langle 1, 1, 9, 0 \rangle, \langle 0, 1 \rangle) \Rightarrow \texttt{AMONG}(4, \langle 4, 5, 5, 4, 1, 1, 1, 9, 0 \rangle, \langle 0, 1 \rangle), where:

1. The first argument of the target constraint, i.e., 4, is equal to the sum of the first arguments of the two source constraints, i.e., $1 + 3$.
2. The second argument of the target constraint, $\langle 4, 5, 5, 4, 1, 1, 1, 9, 0 \rangle$, is equal to the union (without removing duplicates) of the second arguments $\langle 4, 5, 5, 4, 1 \rangle$ and $\langle 1, 1, 9, 0 \rangle$ of the two source constraints.
3. The third arguments of the two source constraints are identical, i.e., $\langle 0, 1 \rangle$, and the third argument of the target constraint.

• \texttt{MAXIMUM}(5, \langle 3, 0, 5, 2, 5 \rangle) \land \texttt{MAXIMUM}(9, \langle 1, 1, 9, 0 \rangle) \Rightarrow \texttt{MAXIMUM}(9, \langle 3, 0, 5, 2, 5, 1, 1, 9, 0 \rangle), where:

1. The first argument of the target constraint, i.e., 9, is equal to the maximum value of the first arguments of the two source constraints, i.e., $\max(5, 9)$.
2. The second argument of the target constraint, $\langle 3, 0, 5, 2, 5, 1, 1, 9, 0 \rangle$, is equal to the union (without removing duplicates) of the second arguments $\langle 3, 0, 5, 2, 5 \rangle$ and $\langle 1, 1, 9, 0 \rangle$ of the two source constraints.

• \texttt{SAME}(\langle 3, 3, 1 \rangle, \langle 3, 1, 3 \rangle) \land \texttt{SAME}(\langle 1, 9, 1, 5, 5 \rangle, \langle 5, 5, 1, 1, 9 \rangle) \Rightarrow \texttt{SAME}(\langle 3, 3, 1, 1, 9, 1, 5, 5 \rangle, \langle 3, 1, 3, 5, 5, 1, 1, 9 \rangle), where:
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

1. The first argument of the target constraint, $\langle 3, 3, 1, 9, 1, 5, 5 \rangle$, is equal to the union (without removing duplicates) of the first arguments $\langle 3, 3, 1 \rangle$ and $\langle 1, 9, 1, 5, 5 \rangle$ of the two source constraints.

2. The second argument of the target constraint, $\langle 3, 1, 3, 5, 5, 1, 1, 9 \rangle$, is equal to the union (without removing duplicates) of the second arguments $\langle 3, 1, 3 \rangle$ and $\langle 5, 5, 1, 1, 9 \rangle$ of the two source constraints.

### 3.7.6 **Air traffic management**

- **ALL_MIN_DIST**,  
- **K_ALLDIFFERENT**,  
- **MULTI_INTER_DISTANCE**,  
- **SORT**.

Denotes that a constraint was used for solving a problem in the area of air traffic management.

### 3.7.7 **Alignment**

- **ORCHARD**.

Denotes that a constraint forces the alignment of different sets of points.
3.7.8 All different

- ALLDIFFERENT,
- ALLDIFFERENT_BETWEEN_SETS,
- ALLDIFFERENT_CST,
- ALLDIFFERENT_CONSECUTIVE_VALUES,
- ALLDIFFERENT_EXCEPT_0,
- ALLDIFFERENT_INTERVAL,
- ALLDIFFERENT_MODULO,
- ALLDIFFERENT_ON_INTERSECTION,
- ALLDIFFERENT_PARTITION,
- GOLOMB,
- K_ALLDIFFERENT,
- OPEN_ALLDIFFERENT,
- PERMUTATION,
- SIZE_MAX_STARTING_SEQ_ALLDIFFERENT,

- SOFT_ALLDIFFERENT_CTR,
- SOFT_ALLDIFFERENT_VAR,
- SYMMETRIC_ALLDIFFERENT,
- SYMMETRIC_ALLDIFFERENT_LOOP,
- WEIGHTED_PARTIAL_ALLDIFF.

Denotes that we have one or several cliques of disequalities or that a constraint is a variation of the ALLDIFFERENT constraint. Variations may be related to relaxation (see, e.g., the ALLDIFFERENT_EXCEPT_0, SOFT_ALLDIFFERENT_CTR, and SOFT_ALLDIFFERENT_VAR constraints), or to specialisation (see, e.g., the SYMMETRIC_ALLDIFFERENT constraint), of the ALLDIFFERENT constraint. Variations may also result from an extension of the notion of disequality (see, e.g., the ALLDIFFERENT_INTERVAL, ALLDIFFERENT_MODULO, ALLDIFFERENT_PARTITION and GOLOMB constraints).
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.9 ▲Alpha-acyclic constraint network(2) ➔ [15 CONS]

- AMONG,
- AMONG_DIFF_0,
- AMONG_INTERVAL,
- AMONG_LOW_UP,
- AMONG_MODULO,

- COUNTS,
- DIFFER_FROM_AT_LEAST_K_POS,
- EXACTLY,
- FULL_GROUP,
- GROUP,
- GROUP_SKIP_ISOLATED_ITEM,
- SLIDING_CARD_SKIP,

Before defining alpha-acyclic constraint network(2) we first need to introduce the following notions:

- The dual graph of a constraint network $\mathcal{N}$ is defined in the following way: to each constraint of $\mathcal{N}$ corresponds a vertex in the dual graph and if two constraints have a non-empty set $S$ of shared variables, there is an edge labelled $S$ between their corresponding vertices in the dual graph.

- An edge in the dual graph of a constraint network is redundant if its variables are shared by every edge along an alternative path between the two end points [144].

- If the subgraph resulting from the removal of the redundant edges of the dual graph is a tree the original constraint network is called $\alpha$-acyclic [168].

Alpha-acyclic constraint network(2) denotes an $\alpha$-acyclic constraint network such that, for any pair of constraints, the two sets of involved variables share at most two variables.

3.7.10 ▼Alpha-acyclic constraint network(3) ➔ [5 CONS]

- FULL_GROUP,
- GROUP,
- GROUP_SKIP_ISOLATED_ITEM,
- ITH_POS_DIFFERENT_FROM_0,
- MIN_SIZE_FULL_ZERO_STRETCH.

Alpha-acyclic constraint network(3) denotes an $\alpha$-acyclic constraint network (see alpha-acyclic constraint network(2)) such that, for any pair of constraints, the two sets of involved variables share at most three variables.
168  3. DESCRIPTION OF THE CATALOGUE

3.7.11 ▼ Apartition ➔

- CHANGE.Continuity.

Denotes that a constraint is defined by two graph constraints having the same initial graph, where each arc of the initial graph belongs to one of the final graphs (but not to both).

3.7.12 ▼ Arc-consistency ➔

Denotes that, for a given constraint involving only domain variables, there is a filtering algorithm that ensures arc-consistency. A constraint \( ctr \) defined on the distinct domain variables \( V_1, \ldots, V_n \) is \textit{arc-consistent} if and only if for every pair \( (V, v) \) such that \( V \) is a domain variable of \( ctr \) and \( v \in \text{dom}(V) \), there exists at least one solution to \( ctr \) in which \( V \) is assigned the value \( v \). As quoted by C. Bessière in [65], “\textit{a different name has often been used for arc-consistency on non-binary constraints}”, like domain consistency, generalised arc-consistency or hyper arc-consistency.
There is also a weaker form of arc-consistency that also try to remove values from the middle of the domain of a variable $V$ (i.e., unlike bound-consistency which focus on reducing the minimum and maximum value of a variable), called range consistency in [65], that is defined in the following way. A constraint $ctr$ defined on the distinct domain variables $V_1, \ldots, V_n$ is range-consistent if and only if, for every pair $(V, v)$ such that $V$ is a domain variable of $ctr$ and $v \in \text{dom}(V)$, there exists at least a solution to $ctr$ in which, (1) $V$ is assigned the value $v$, and (2) each variable $U \in \{V_1, \ldots, V_n\}$ distinct from $V$ is assigned a value located in its range $[U, \bar{U}]$.

- ELEM_FROM_TO,
- ELEMENT,
- ELEMENTS_ALLDIFFERENT,
- ELEMENT_LESSEQ,
- ELEMENT_GREATEREQ,
- ELEMENT_MATRIX,
- ELEMENT_PRODUCT,
- ELEMENT_SPARSE.

A constraint that allows for expressing simple array equations.

3.7.15 ▼Assigning and scheduling tasks that run in parallel ➔ [3 CONS]

- DIFFN,
- GEOST,
- GEOST_TIME.

Consider a set of tasks defined by a set of subtasks, where each subtask has the following attributes:

- A start telling when the subtask starts.
- A duration giving the duration of the subtask.
- A deadline indicating the date by which the subtask must be finished.
- A person indicating which person performs the subtask.
Both the start and the person correspond to decision variables, while the duration and the deadline are integers. Since all subtasks of a same task must run in parallel, their starts, durations and deadlines are identical. Since a person can perform at most one task at each timepoint, persons assigned to the subtasks of a same task must all be distinct. We also assume that a subtask cannot be preempted.

As an instance of this pattern, consider the problem of scheduling surgical operations in a hospital. Each surgery corresponds to a task that requires a number of persons with specific skills; these persons will all work together during the operation (e.g., typically an anaesthetist, a surgeon and one or several nurses). Moreover, each person has his own calendar defining his unavailability. On the one hand, let us assume we have two anaesthetists, two surgeons and four nurses, labelled from 1 to 8. Each of them has the following unavailability over the time horizon $[0, 24]$:

- The first anaesthetist is not available during the time periods $[0, 1]$, $[5, 6]$, and $[12, 16]$.
- The second anaesthetist is not available during the time periods $[0, 2]$, $[6, 6]$, $[15, 15]$, and $[22, 22]$.
- The first surgeon is not available during the time periods $[0, 1]$, $[8, 9]$, and $[13, 14]$.
- The second surgeon is not available during the time periods $[5, 5]$, and $[20, 21]$.
- The four nurses are all not available during the time periods $[0, 0]$, $[7, 7]$, $[12, 12]$, and $[22, 22]$.

On the other hand, let us suppose we have to schedule five surgery tasks, each of them requiring a specific team:

- Task $t_1$ needs one anaesthetist, one surgeon and two nurses during two consecutive time slots.
- Task $t_2$ needs one anaesthetist, one surgeon and one nurse during four consecutive time slots.
- Task $t_3$ needs one anaesthetist, two surgeons and two nurses during three consecutive time slots.
- Task $t_4$ needs one anaesthetist, one surgeon and three nurses during two consecutive time slots.
- Task $t_5$ needs one anaesthetist, one surgeon and one nurse during six consecutive time slots.

Moreover, tasks $t_1$, $t_2$, $t_3$, $t_4$ and $t_5$ must be respectively completed no later than time-point 12, 15, 24, 24 and 24. The problem is modelled by using a two-dimensional GEOST constraint, where the first and second dimensions respectively correspond to the time and resource axes. For each person required by a task we create a rectangle of length corresponding to the necessary duration and of height 1 (since it requires one
person). The coordinates of the lower left point of the rectangle correspond to the start of the corresponding task as well as to the person that will be assigned to the subtask (i.e., a value between 1 and 2 for an anaesthetist, a value between 3 and 4 for a surgeon, and a value between 5 and 8 for a nurse). Both the start and the person correspond to a domain variable. Each unavailability period of an anaesthetist, a surgeon and a nurse is modelled by introducing a fixed rectangle (i.e., its coordinates are set to the start of the unavailability period and to the person to which the unavailability belongs; its duration is set to the duration of the unavailability period) that prevent tasks overlapping the corresponding time period for a specific person. This leads to the following **GEOST** constraint,
3. DESCRIPTION OF THE CATALOGUE

- $\text{oid} = 5$: $t = (0,0)$, $1 = (5,1)$, $\text{sid} = 6$: $t = (0,0)$, $1 = (6,1)$

Figure 3.2: A solution to the surgery scheduling problem using four nurses where the start and the latest completion time of each task are respectively shown in bold and in red; a solution using only 3 nurses can be obtained by starting task $t_4$ at instant 13 and by assigning it to the second anaesthetist rather than to the first one.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

A deadline constraint for a surgery starting at \( o \) and of duration \( d \) is modelled by a precedence constraint of the form \( o + d \leq \text{deadline} \). This leads to the five constraints \( o_1 + 2 \leq 12, o_2 + 4 \leq 15, o_3 + 3 \leq 24, o_4 + 2 \leq 24 \), and \( o_5 + 6 \leq 24 \). Finally, we break symmetry on the assignment variables corresponding to a group of similar persons. In the example, the four nurses are similar since (1) they all have exactly the same unavailability periods, and since (2) no task requires a specific nurse. For each task using more than one nurse (i.e., tasks \( t_1, t_3, \) and \( t_4 \)) this leads to a chain of strict inequalities, i.e., \( n_{11} < n_{12}, n_{31} < n_{32}, \) and \( n_{41} < n_{42} < n_{43} \). Figure 3.2 depicts a solution to the problem corresponding to the assignment

A constraint related to assignment problems (i.e., K\_ALLDIFFERENT), or a constraint putting a restriction on all items that are assigned to the same equivalence class or on all equivalence classes that are actually used. Usually an equivalence class corresponds to a single value (see, e.g., the BALANCE, BIN\_PACKING, GLOBAL\_CARDINALITY, and SUM\_OF\_WEIGHTS\_OF\_DISTINCT\_VALUES constraints), to an interval of consecutive values (see, e.g., the BALANCE\_INTERVAL, INTERVAL\_AND\_COUNT, and INTERVAL\_AND\_SUM constraints) or to all values that are congruent modulo a given number (see, e.g., the BALANCE\_MODULO constraint). The restriction on all items that are assigned to the same equivalence class can be, for example, a constraint on the number of items (see, e.g., the CARDINALITY\_ATLEAST, CARDINALITY\_ATMOST, GLOBAL\_CARDINALITY, and GLOBAL\_CARDINALITY\_LOW\_UP constraints) or a constraint on the sum of a specific attribute (see, e.g., the BIN\_PACKING, and INTERVAL\_AND\_SUM constraints).

### 3.7.17 Assignment dimension

- DIFFN (attribute ori of ORTHOTOPE collection for which siz = 1),
- GEOST (attribute x of OBJECTS collection for which l = 1),
- GEOST\_TIME (attribute x of OBJECTS collection for which l = 1),
- INTERVAL\_AND\_COUNT (attribute origin of TASKS collection),
- INTERVAL\_AND\_SUM (attribute origin of TASKS collection).

A constraint for handling placement problems involving orthotopes, where one of the dimensions of the placement space is so called an assignment dimension (i.e., one of the attributes of a collection passed as argument indicates the assignment dimension — the attribute is shown in parenthesis for each constraint). In order to illustrate the notion of assignment dimension let us first introduce three typical examples described in Figure 3.3:

- Part (A) of Figure 3.3 considers a scheduling problem where we have both to assign a task to a machine and to fix its start to a time-point, in such a way that two
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

Tasks that overlap in time are not assigned to the same machine. In this context the different potential machines where tasks can be assigned is called an assignment dimension. This problem can be directly modelled by a CUMULATIVES, a DIFFN or a GEOST constraint. The corresponding three ground instances encoding the example are (attributes related to the assignment dimension are shown in bold and red):

oid − 2 sid − 2 x − ⟨1, 1, 2⟩,
oid − 3 sid − 3 x − ⟨2, 1, 1⟩
⟨sid − 1 t − ⟨0, 0, 0⟩ 1 − ⟨1, 1, 2⟩,
sid − 2 t − ⟨0, 0, 0⟩ 1 − ⟨1, 1, 1⟩,
sid − 3 t − ⟨0, 0, 0⟩ 1 − ⟨1, 2, 1⟩⟩)

In summary, within the context of placement problems that use a constraint like DIFFN or GEOST, the coordinate of an object in the assignment dimension corresponds to the resource to which the object is assigned. Note that the size of an object in the assignment dimension is always set to 1. This stems from the fact that an object is assigned to a single resource.

Using constraints like COLOURED_CUMULATIVES, CUMULATIVES, DIFFN, GEOST or GEOST_TIME allows to model directly with a single global constraint such problems without knowing in advance to which machine, to which rectangular piece, to which container, a task, a rectangle, a box will be assigned. For each object the potential values of its assignment variable provide the machines, the rectangular pieces, the containers to which the object can possibly be assigned. Note that this allows to avoid 0-1 variables for modelling such problems.
Figure 3.3: Three illustrations of the notion of assignment dimension where the assignment dimension is shown in red

Within constraints like \textsc{interval\_and\_count} or \textsc{interval\_and\_sum} the concept of assignment dimension is extended from the fact that a variable is assigned a value to the fact that a variable is assigned an interval (i.e., a value in an interval).

3.7.18 \hspace{1cm} ▼ Assignment to the same set of values \hspace{1cm} [9 CONS]

- \textsc{bin\_packing},
- \textsc{bin\_packing\_capa},
- \textsc{coloured\_cumulatives},
- \textsc{cumulatives},
- \textsc{diffn},
- \textsc{elem},
- \textsc{element},
- \textsc{geost},
- \textsc{geost\_time}.

Given several mutually disjoint finite sets of values $S_1, S_2, \ldots, S_m \ (m > 1)$ such that $S_1 \cup S_2 \cup \cdots \cup S_m = \{1, 2, \ldots, p\}$, as well as a set of variables $V_1, V_2, \ldots, V_n$, the assignment to the same set of values subproblem consists of assigning all variables $V_1, V_2, \ldots, V_n$ values that belong to the same set $S_i \ (1 \leq i \leq m)$. As we will see later on, this subproblem arises naturally in many resource assignment problems where an additional constraint between variables $V_1, V_2, \ldots, V_n$ also has to hold. The subproblem can be modelled as a conjunction of \textsc{element} constraints of the form:

\begin{align*}
&\textsc{element}\left(V_1, \langle \text{set\_of\_val}_1, \text{set\_of\_val}_2, \ldots, \text{set\_of\_val}_p \rangle, \text{set\_index} \right) \land \\
&\textsc{element}\left(V_2, \langle \text{set\_of\_val}_1, \text{set\_of\_val}_2, \ldots, \text{set\_of\_val}_p \rangle, \text{set\_index} \right) \land \\
&\cdots \\
&\textsc{element}\left(V_n, \langle \text{set\_of\_val}_1, \text{set\_of\_val}_2, \ldots, \text{set\_of\_val}_p \rangle, \text{set\_index} \right),
\end{align*}

where $\text{set\_of\_val}_i = j$ if and only if $i \in S_j$ (i.e., $\text{set\_of\_val}_i$ corresponds to the index
of the set that contains value $i$). The $k$-th \texttt{ELEMENT} constraint expresses that variable $V_k$ is assigned a value in set $S_{\text{SET INDEX}}$. Since all \texttt{ELEMENT} constraints share the same third argument this forces all variables $V_1, V_2, \ldots, V_n$ to be assigned a value within the same set. Note that this conjunction of \texttt{ELEMENT} constraints corresponds to a Berge-acyclic constraint network. Consequently, one can achieve arc-consistency on this subproblem provided that arc-consistency is enforced on each \texttt{ELEMENT} constraint.

As an example, consider the four sets of values $S_1 = \{3, 4, 8\}$, $S_2 = \{1, 5\}$, $S_3 = \{6, 7\}$, and $S_4 = \{2, 9\}$, as well as four variables $w, x, y$ and $z$ that all must be assigned values that belong to the same set $S_s$ ($1 \leq s \leq 4$). This leads to the following conjunction of \texttt{ELEMENT} constraints:

\begin{align*}
\text{ELEMENT}(w, (2, 4, 1, 1, 2, 3, 3, 1, 4), s) \land \\
\text{ELEMENT}(x, (2, 4, 1, 1, 2, 3, 3, 1, 4), s) \land \\
\text{ELEMENT}(y, (2, 4, 1, 1, 2, 3, 3, 1, 4), s) \land \\
\text{ELEMENT}(z, (2, 4, 1, 1, 2, 3, 3, 1, 4), s).
\end{align*}

The first entry of the table $(2, 4, 1, 1, 2, 3, 3, 1, 4)$ is set to 2 since value 1 belongs to $S_2$. Similarly, the second entry of the table is of set of 4 since value 2 belongs to $S_4$. The same logic is used for building up the other entries of the table.

A generalisation of this subproblem consists in lifting the restriction that the sets of values $S_1, S_2, \ldots, S_m$ are mutually disjoint. The only change to adapt the previous model is to replace within each \texttt{ELEMENT} constraint each value $\text{val}_i$ ($1 \leq i \leq p$) by a value variable $\text{Val}_j$ (i.e., each value of a value variable represents a set containing $i$), where $j \in \text{dom}(\text{Val}_i)$ if and only if $i \in S_j$. Distinct \texttt{ELEMENT} constraints will get distinct value variables. As an example, consider the previous four sets of values where we add value 2 to $S_1$ and value 5 to $S_3$. We now have the sets $S_1 = \{2, 3, 4, 8\}$, $S_2 = \{1, 5\}$, $S_3 = \{5, 6, 7\}$, and $S_4 = \{2, 9\}$ where value 2 occurs both in $S_1$ and $S_4$, and value 5 appears both in $S_2$ and $S_3$. This leads to the following conjunction of constraints:

\begin{align*}
\text{IN}(a_1, (1, 4)) \land \text{IN}(b_1, (2, 3)) \land \text{ELEMENT}(w, (2, a_1, 1, 1, b_1, 3, 3, 1, 4), s) \land \\
\text{IN}(a_2, (1, 4)) \land \text{IN}(b_2, (2, 3)) \land \text{ELEMENT}(x, (2, a_2, 1, 1, b_2, 3, 3, 1, 4), s) \land \\
\text{IN}(a_3, (1, 4)) \land \text{IN}(b_3, (2, 3)) \land \text{ELEMENT}(y, (2, a_3, 1, 1, b_3, 3, 3, 1, 4), s) \land \\
\text{IN}(a_4, (1, 4)) \land \text{IN}(b_4, (2, 3)) \land \text{ELEMENT}(z, (2, a_4, 1, 1, b_4, 3, 3, 1, 4), s).
\end{align*}

The domains of the variables $a_i$ $(1 \leq i \leq 4)$ associated with the second entry of the table\footnote{The table corresponds to the second argument of the \texttt{ELEMENT} constraint.} of the \texttt{ELEMENT} constraints is set to 1 and 4 since value 2 belongs to $S_1$ and to $S_4$. Similarly, the domain of variables $b_i$ $(1 \leq i \leq 4)$ associated with the fifth entry is set to 2 and 3 since value 5 belongs to $S_2$ and $S_3$. Note that, since variables $a_1, a_2$, $a_3, a_4, b_1, b_2, b_3, b_4$ are distinct, the corresponding constraint network is still Berge-acyclic. We now provide an alternative model where the $i^{th}$ entry of the table of the $k^{th}$ ($1 \leq k \leq n$) \texttt{ELEMENT} constraint corresponds to a variable $S_{ki}$ for which the initial domain is the set of values that belong to $S_i$ ($1 \leq i \leq m$). We have a conjunction of \texttt{ELEMENT} constraints of the form:

\begin{align*}
\text{ELEMENT}(\text{SET INDEX}, (S_{11}, S_{12}, \ldots, S_{1m}), V_1) \land \\
\text{ELEMENT}(\text{SET INDEX}, (S_{21}, S_{22}, \ldots, S_{2m}), V_2) \land \\
\ldots
\end{align*}
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

\( \text{ELEMENT}(\text{SET}_\text{INDEX}, (S_{n1}, S_{n2}, \ldots, S_{nm}), V_n) \),

where \( \text{SET}_\text{INDEX} \) is a variable ranging from 1 to \( m \) designating the selected set. This model perhaps seems more natural. However unlike the first model, when the sets \( S_1, S_2, \ldots, S_m \) are mutually disjoint, it enforces using variables instead of integers in the table of each \text{ELEMENT} constraint. Like the first model, it is Berge-acyclic.

Now that we have presented two dual models for the assignment to the same set of values subproblem, we introduce the \textit{resource assignment with groups} pattern, which uses several instances of the subproblem. We consider a set of tasks \( t_1, t_2, \ldots, t_q \) \((q \geq 1)\) tasks, where each task \( t_i \) \((1 \leq i \leq q)\) is decomposed into \( s_i \) subtasks \( t_{ij} \) \((1 \leq j \leq s_i)\). All subtasks that belong to one and the same task should be assigned the same group, where groups are defined by the finite sets of values \( S_1, S_2, \ldots, S_m \) \((m > 1)\) introduced early on. For this purpose an \textit{assignment variable} and a \textit{group variable} are respectively associated with each subtask and each task. In addition, we also have a resource constraint involving all subtasks. This resource constraint has an \textit{assignment dimension} corresponding to the different resources where subtasks can potentially be assigned. To each resource corresponds a value of \( S_1 \cup S_2 \cup \cdots \cup S_m = \{1, 2, \ldots, p\}\). Depending on the kind of resource constraint we have (e.g., \text{BIN\_PACKING}, \text{CUMULATIVES}, \text{DIFFN}, \text{GEOST}), each subtask has additional attributes that characterise it. For example, if we have a \text{BIN\_PACKING} constraint then, in addition to the assignment dimension that corresponds to the bin where a subtask will be assigned, we also have a weight attribute that describes how much space a subtask uses in a bin. Then the \text{BIN\_PACKING} constraint expresses that the total weight of the subtasks in each bin does not exceed a given fixed capacity.

Figure 3.4: Illustration of the constraint network associated with the \textit{resource assignment with groups} pattern

Figure 3.4 illustrates the constraint network associated with the \textit{resource assign-}
ment with groups pattern. Lower circles represent the group variables associated with
the different tasks (three tasks in the example), while all the other circles represent
the attributes of the different subtasks (i.e., vertically aligned circles correspond to the
attributes of a given subtask). All circles that are associated with the same task are
coloured with the same colour. As said before, each subtask has an attribute that gives
the resource to which the resource will be assigned (called assignment variables in Figure
3.4) and other attributes that depend of the resource constraint we are considering
(called other subtask attributes in the Figure). Each blue rounded box corresponds to
a group constraint which enforces all subtasks of a given task to be assigned the same
group (i.e., within this blue box, each line segment represents an ELEMENT constraint
of the assignment to the same set of values subproblem). Finally, the pink rounded box
represents the resource constraint that involves all subtasks.

Before illustrating the resource assignment with groups pattern on a particular re-
source constraint, we first point out a potential weakness that is inherent to this con-
straint network, no matter what kind of resource constraint we use. When pruning the
assignment variables, the resource constraint will ignore the groups (since the resource
constraint is not aware of the ELEMENT constraints) and will therefore miss some filtering.
Consequently one may complete the constraint network by some global necessary
conditions. When fixing variables it may be a good idea to fix all variables that are
attached to one task before considering the next task. While fixing the variables of a
task one may first assign its group variable, and second fix the variables of its subtasks;
again we may prefer to fix all variables of a subtask before considering the next subtask.
The idea behind this heuristic is to try to avoid the creation of infeasible subproblems
during search.

Figure 3.5: Illustration of the resource assignment with groups pattern in the context
of a BIN_PACKING resource constraint (subtasks of the same colour are assigned to the
same group of bins)

Figure 3.5 illustrates the resource assignment with groups pattern when the re-
source constraint corresponds to a BIN_PACKING constraint. As in Figure 3.4, we have
three tasks $t_1, t_2$ and $t_3$ such that:

- Three subtasks $t_{11}, t_{12}$ and $t_{13}$ are associated with task $t_1$. They have a respective
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

weight of 2, 3 and 2 and are coloured in green in Figure 3.5.

- Two subtasks $t_{21}$ and $t_{22}$ of respective weight 2 and 3 are associated with task $t_2$. They are coloured in yellow.

- Two subtasks $t_{31}$ and $t_{32}$ of respective weight 2 and 1 are associated with task $t_3$. They are coloured in orange.

We consider 9 bins that are partitioned into four groups of bins $S_1 = \{3, 4, 8\}$ (coloured in light blue in Figure 3.5), $S_2 = \{1, 5\}$ (coloured in light green), $S_3 = \{6, 7\}$ (coloured in light brown), and $S_4 = \{2, 9\}$ (coloured in light violet), and enforce that all subtasks that are associated with the same task are assigned the same group of bins. In addition, the sum of the weights of the subtasks that are assigned the same bin should not exceed the capacity of the bins, 5 in our example. Within the solution depicted by Figure 3.5, all constraints are satisfied since:

1. For each task, all its subtasks are assigned the same group of bins (i.e., all subtasks that have the same colour are assigned bins with the same colour).

2. The capacity constraint of each bin is respected (i.e., the overall capacity of five is never exceeded).

The conjunction of constraints corresponding to this solution is:

```
ELEMENT(4, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 1) ∧
ELEMENT(8, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 1) ∧
ELEMENT(4, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 1) ∧
ELEMENT(2, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 4) ∧
ELEMENT(9, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 4) ∧
ELEMENT(2, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 4) ∧
ELEMENT(9, ⟨2, 4, 1, 1, 2, 3, 3, 1, 4⟩, 4) ∧
BIN_PACKING(5, ⟨bin − 4 weight − 2, bin − 8 weight − 3, bin − 4 weight − 2, bin − 2 weight − 2, bin − 9 weight − 3, bin − 2 weight − 2, bin − 9 weight − 1⟩).
```

For each subtask we have one ELEMENT constraint expressing that all subtasks of a given task are assigned the same group of bins. Finally we have one BIN_PACKING constraint expressing the capacity condition.

We now quote two concrete examples of the resource assignment with groups pattern:

- Given, (1) a set of jobs where each job is decomposed into a set of tasks, each of them requiring an amount of memory for its execution, as well as (2) a set of potential machines, each of them having a given available memory, organised into clusters, the problem is to:
  
  - Assign all tasks to machines in such a way that tasks from the same job are assigned the same cluster.
  - Fulfil the available memory constraint of each machine (i.e., the sum of the required memory of all tasks that are assigned a given machine does not exceed the machine available memory).
3. DESCRIPTION OF THE CATALOGUE

This concrete problem corresponds to the example presented in Figure 3.5.

- Given, (1) a set of maintenance activities where each maintenance activity is decomposed into a set of subactivities, each of them requiring a specific skill and a given duration, as well as (2) a set of technicians, each of them having its own home base location and its own working time window, the problem is to:
  
  - Assign all maintenance subactivities to technicians in such a way that subactivities from the same activity are assigned technicians that have the same home base location (i.e., each subactivity should be assigned a single technician).
  
  - Fulfil both the working time window of each technician, and the fact that subactivities that are assigned the same technician should not overlap (i.e., subactivities must be assigned a starting time and preemption is not allowed).

In this problem we replace the BIN_PACKING constraint by a CUMULATIVES(TASKS, MACHINES, ≤) constraint. To each item of the TASKS collection corresponds a subactivity, such that:

  - Its machine attribute designates the potential technicians that can take care of this subactivity.
  
  - Its origin attribute corresponds to the timepoint where the subactivity will actually start.
  
  - Its duration attribute is set to the duration of the corresponding subactivity.
  
  - Its end attribute is equal to origin + duration.
  
  - Its height attribute is set to one.

In addition to the subactivities, we also introduce for each technician two fixed dummy tasks for preventing assigning subactivities outside its time window. To each item of the MACHINES collection corresponds a technician, such that:

  - Its id attribute is a fixed integer that uniquely identifies the technician.
  
  - Its capacity attribute is set to one since it cannot perform more than one subactivity at any timepoint.

A constraint for which the catalogue provides a deterministic automaton for the ground case. This automaton can usually be used for deriving mechanically a filtering algorithm for the general case. We have the following three types of deterministic automata:

- Deterministic automata without counters and without array of counters,
- Deterministic automata with counters but without array of counters,
- Deterministic automata with array of counters and possibly with counters.

Figure 3.6 shows three automata respectively associated with the GLOBAL_CONTIGUITY, the EXACTLY and the ALLDIFFERENT constraints. These automata correspond to the three types we described above.
3. DESCRIPTION OF THE CATALOGUE

- NO_VALLEY,
- PEAK,
- VALLEY.

A constraint for which the catalogue provides an automaton belonging to the following category:

- Symbols of the alphabet are split in two categories: neutral ones and non-neutral ones.

- Non-neutral symbols correspond to symbols occurring on transitions between two distinct states, while neutral symbols correspond to all the other symbols of the alphabet.

- Self-loops labelled by a neutral symbol do not modify any counter.

- Ignoring transitions labelled by neutral symbols, every state has its incoming transitions labelled by the same non-neutral symbol.

- Ignoring transitions labelled by neutral symbols, outgoing transitions of a state are not labelled by the symbol associated with its incoming non-loop transitions.

For such automata we define the semantics of a state $s$ as the regular expression associated with the language fragment obtained from entering state $s$ to just before leaving state $s$.

As an example, consider the VALLEY constraint and its automaton depicted by Figure 3.7. The alphabet $\mathcal{A}$ corresponds to the set of symbols $\{<, =, >\}$ from which $<
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

FIGURE 3.7: Semantics of the states of the automaton of the VALLEY constraint (an accepting state is denoted graphically by a double circle)

and > are non-neutral symbols (i.e., the symbols associated with the transitions between states s and u), and = is a neutral symbol. First there is no counter modification on all self-loops. If we remove the self-loops carrying the neutral symbol = we have that:

- All incoming transitions in state s are labelled by the non-symbol <, and all outgoing transitions from state s are not labelled by <.
- All incoming transitions in state u are labelled by the non-symbol >, and all outgoing transitions from state u are not labelled by >.

The corresponding state semantics is given by the upper-leftmost box.

A constraint for which the catalogue provides a deterministic automaton without counters and without array of counters. Note that the filtering algorithm [317] and the reformulation [39] that were initially done in the context of deterministic automata can also be used for non-deterministic automata. All these constraints are also annotated with the keyword reified automaton constraint.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.26 Autoref \[1\] CONS

- \textsc{GLOBAL\_CARDINALITY}.

A constraint that allows for modelling the \textit{autoref} problem with a single constraint. The \textit{autoref} problem is a generalisation of the problem of finding a \textit{magic series} and can be defined in the following way. Given an integer \(n > 0\) and an integer \(m \geq 0\), the problem is to find a non-empty finite series \(S = (s_0, s_1, \ldots, s_n, s_{n+1})\) such that (1) there are \(s_i\) occurrences of \(i\) in \(S\) for each integer \(i\) ranging from 0 to \(n\), and (2) \(s_{n+1} = m\). This leads to the following model:

\[
\begin{pmatrix}
\langle \text{var} - s_0, \text{var} - s_1, \ldots, \text{var} - s_n, \text{var} - m \rangle, \\
\text{val} - 0 \ n\text{occurrence} - s_0, \\
\text{val} - 1 \ n\text{occurrence} - s_1, \\
\vdots \\
\text{val} - n \ n\text{occurrence} - s_n
\end{pmatrix}
\]

23, 2, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 5 and 23, 3, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 0, 0, 5 are the two unique solutions for \(n = 27\) and \(m = 5\).

3.7.27 Balanced assignment \[8\] CONS

- \textsc{ALL\_BALANCE},
- \textsc{BALANCE},
- \textsc{BALANCE\_INTERVAL},
- \textsc{BALANCE\_MODULO},
- \textsc{BALANCE\_PARTITION},
- \textsc{DEVIATION},
- \textsc{MAXIMUM},
- \textsc{SPREAD}.

A constraint to obtain a balanced assignment over a set of domain variables. Given a set of domain variables \(\{x_1, x_2, \ldots, x_n\}\), some classical balance criteria reported in [379] are:

- The \textit{maximum value}, i.e., the maximum value over \(x_i \ (i \in [1, n])\) can be modelled with a \textsc{MAXIMUM} constraint.
- The \textit{maximum deviation}, i.e., the maximum value over \(x_i - \frac{\sum_{j \in [1, n]} x_j}{n} \ (i \in [1, n])\).
• The total deviation, i.e., $\sum_{i \in [1,n]} |x_i - \frac{\sum_{j \in [1,n]} x_j}{n}|$ can be modelled with a DEVIATION constraint [382, 380].

• The total quadratic deviation, i.e, $\sum_{i \in [1,n]} (x_i - \frac{\sum_{j \in [1,n]} x_j}{n})^2$ can be modelled with a SPREAD constraint [318, 381].

3.7.28 ▼Balanced tree ➔ [1 CONS]

• TREE_RANGE.

A constraint that allows for expressing that we want to cover a digraph by one (or more) balanced tree. A balanced tree is a tree where no leaf is much farther away than a given threshold from the root than any other leaf. The distance between a leaf and the root of a tree is the number of vertices on the path from the root to the leaf.

- XOR

A constraint for which the decomposition associated with its usually counter-free deterministic automaton\(^8\) is Berge-acyclic. Arc-consistency for a Berge-acyclic constraint network is achieved by making each constraint of the corresponding network arc-consistent [25]. A constraint network for which the corresponding intersection graph does not contain any cycle and such that, for any pair of constraints, the two sets of involved variables share at most one variable is Berge-acyclic, where Berge-acyclic is defined by the following two conditions:

1. There is no more than one shared variable between any pair of constraints,

2. The hypergraph corresponding to the constraint network does not contain any cycle. Within [64, page 150] a cycle of an hypergraph \(H\) is defined as “Let \(H\) be an hypergraph on a finite set \(X\). A cycle of length \(k\) (\(k \geq 2\)) is a sequence \((x_1, E_1, x_2, E_2, x_3, \ldots, E_k, x_1)\) such that (1) \(E_1, E_2, \ldots, E_k\) are distinct edges of \(H\), (2) \(x_1, x_2, \ldots, x_k\) are distinct vertices of \(H\), (3) \(x_i, x_{i+1} \in E_i\) (\(i = 1, 2, \ldots, k-1\)), (4) \(x_k, x_1 \in E_k\)”.

The intersection graph of a constraint network is built in the following way: to each vertex corresponds a constraint and there is an edge between two vertices if and only if the sets of variables involved in the two corresponding constraints intersect.

Parts (A), (B), (C) and (D) of Figure 3.8 provide four examples of constraint networks, while parts (E), (F), (G) and (F) give their corresponding intersection graphs.

1. The constraint network corresponding to part (A) is Berge-acyclic since its corresponding intersection graph (E) does not contain any cycle and since there is no more than one shared variable between any pair of constraints.

2. The constraint network corresponding to part (B) is not Berge-acyclic since its hypergraph (B) contains a cycle.

3. The constraint network corresponding to (C) is also not Berge-acyclic since its third and fourth constraints share more than one variable.

\(^8\)All the above constraints, except AMONG, CHANGE, and SMOOTH have a deterministic counter-free automaton. The AMONG constraint has an automaton involving one counter and a single state, see Figure 5.61, while the CHANGE and the SMOOTH constraints have a counter-free non deterministic automaton, see Figures 5.162 and 5.738.
4. Finally, the constraint network corresponding to (D) is Berge acyclic, even though its intersection graph (H) has a cycle, since its hypergraph (D) does not contain any cycle and since there is no more than one shared variable between any pair of constraints.

If we execute the filtering algorithm of each constraint of a Berge-acyclic constraint network $N$ in an appropriate order then each constraint needs only to be waken twice in order to reach the fix-point. A static ordering for waking the constraints of $N$ can be determined as follows:

- Consider the intersection graph $G_N$ associated with the constraint network $N$. We perform a topological sort on $G_N$, which always first selects in the remaining part of $G_N$ a vertex (i.e., a constraint) which has only a single neighbour. Let $C_1, C_2, \ldots, C_n$ be the constraints successively removed by the topological sort.

- Then, the static ordering for reaching a fix-point is given by the sequence $C_1, C_2, \ldots, C_{n-1}, C_n, C_{n-1}, \ldots, C_2, C_1$, where each constraint is woken at most twice. This can be done by using the notion of propagator group [258]. This facility allows the user of a solver controlling the order of execution of a group of constraints. Propagator groups are useful, both to guaranty the theoretical worst case complexity of a decomposition, and for accelerating convergence to the fix-point in practice.

If we consider the Berge-acyclic constraint network given by Part (D) of Figure 3.8 an appropriate order for waking the constraints could be, for example, CTR$_1$, CTR$_4$, CTR$_2$, CTR$_3$, CTR$_2$, CTR$_4$, CTR$_1$.

For heuristics that try creating a Berge-acyclic constraint network see also the keyword heuristics and Berge-acyclic constraint network.

Denotes that, for a given constraint, a bipartite matching algorithm can be used within its filtering algorithm. A bipartite matching is a subgraph that pairs every vertex of a bipartite graph with exactly one other vertex. A bipartite graph is a graph for
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

Figure 3.9: (A) A bipartite graph and (B) one of its bipartite matching

which the set of vertices can be partitioned in two parts such that no two vertices in the
same part are joined by an edge. Part (A) of Figure 3.9 shows a bipartite graph with a
possible division of the vertices in black and white, while part (B) depicts with a thick
line a bipartite matching of this graph.

A used generalisation so called degree-matching of a graph is a spanning sugraph
where every vertex is associated with the bound degree of the matched edges.

3.7.34 ▼Bipartite matching in convex bipartite graphs ➤ [2 CONS]

• ALLDIFFERENT,
• ALLDIFFERENT,CST.

Denotes that, for a given constraint, a bipartite matching algorithm using Glover’s
rule for constructing a maximum matching of a convex bipartite graph can be used.
Given a convex bipartite graph $G = (U, V, E)$ where $U = \{u_1, u_2, \ldots, u_n\}$ and
$V = \{v_1, v_2, \ldots, v_m\}$, Glover [205] showed how to efficiently compute a maximum
matching in such a graph:

1. First start with the empty matching.
2. Second for each vertex $v_j$ of $V$, $(j = 1, 2, \ldots, m)$, if $v_j$ has still a free neighbour
   in $U$, then add to the current matching the edge $(u_i, v_j)$ for which $u_i$ is free and
   $\alpha_i = \max\{j : (x_i, y_j) \in E, y_j \in V\}$ is as small as possible.

3.7.35 ▶ Boolean channel ➞

- **DOMAIN_CONSTRAINT.**

  A constraint that allows for making the link between a set of 0-1 variables \(B_1, B_2, \ldots, B_n\) and a domain variable \(V\). It forces a condition of the form \(V = i \iff B_i = 1\).

3.7.36 ▶ Boolean constraint ➞

- AND,
- CLAUSE_AND,
- CLAUSE_OR,
- EQUIVALENT,
- IMPLY,
- NAND,
- NOR,
- OR,
- XOR.

A Boolean constraint is a constraint of the form \(v = f(v_1, \ldots, v_n)\) \((n \geq 2)\) where \(v, v_1, \ldots, v_n\) are 0-1 variables and where \(f(v_1, \ldots, v_n)\) is a logical expression involving connectors, such as \(\neg, \lor, \text{ or } \land\).

3.7.37 ▶ Border ➞

- **PERIOD.**

  A constraint that can be related to the notion of border, which we define now. Given a sequence \(s = uvv\), \(r\) is a prefix of \(s\) when \(u\) is empty, \(r\) is a suffix of \(s\) when \(v\) is empty, \(r\) is a proper factor of \(s\) when \(r \neq s\). A border of a non-empty sequence \(s\) is a proper factor of \(s\), which is both a prefix and a suffix of \(s\). We have that the smallest period of a sequence \(s\) is equal to the size of \(s\) minus the length of the longest border of \(s\).
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.38 **Bound-consistency**  

- ALLDIFFERENT,
- ALL_MIN_DIST,
- ATMOST1,
- ATMOST_NVALUE,
- NVALUE,
- GLOBAL_CARDINALITY,
- GLOBAL_CARDINALITY_LOW_UP,
- INCREASING_SUM,
- K_ALLDIFFERENT,
- MULTI_INTER_DISTANCE,
- SAME,
- SAME_AND_GLOBAL_CARDINALITY_LOW_UP,
- SLIDING_SUM,
- SOFT_ALL_EQUAL_MAX_VAR,
- SOFT_ALL_EQUAL_MIN_CTR,
- SORT,
- SUM_FREE,
- SUM_OF_INCREMENT,
- USED_BY.

Denotes that, for a given constraint, there is a filtering algorithm or a reformulation in term of other constraints that ensures bound-consistency for its domain variables.\(^9\) A filtering algorithm or a reformulation ensure bound-consistency for a given constraint \(ctr\) using distinct domain variables if and only if for every domain variable \(V\) of \(ctr\):

- There exists at least one solution to \(ctr\) such that \(V = V\) and every other domain variable \(W\) of \(ctr\) is assigned to a value located in its range \([W, W]\).
- There exists at least one solution to \(ctr\) such that \(V = \bar{V}\) and every other domain variable \(W\) of \(ctr\) is assigned to a value located in its range \([W, W]\).

This consistency is called bound(Z) consistency in [65]. One of its interest is that it sometimes gives the opportunity to come up with a filtering algorithm that has a lower complexity than the algorithm that achieves arc-consistency. Discarding holes from the domain variables usually leads to graphs with a specific structure for which one can take advantage in order to derive more efficient graph algorithms. Filtering algorithms that achieve bound-consistency can also be used in a pre-processing phase before applying a more costly filtering algorithm that achieves arc-consistency.

Note that there is a second definition of bound-consistency, called bound(D) consistency in [65], where the range \([W, W]\) is replaced by the domain of the variable \(W\). However within the context of global constraints most filtering algorithms do not refer to this second definition.

Finally, within the context of constraints involving only set variables, bound-consistency is defined in the following way. A constraint \(ctr\) defined on distinct set variables is bound-consistent if and only if for every pair \((V, v)\) such that \(V\) is a set variable of \(ctr\) and \(v\) an integer value, if \(v \in V\) then \(v\) belongs to the set assigned to \(V\) in all solutions to \(ctr\) and if \(v \in V \setminus V\) then \(v\) belongs to the set assigned to \(V\) in at least one solution and is excluded from this set in at least one solution.

---

\(^9\)In the context of the NVALUE constraint, bound-consistency is only achieved if and only if, the minimum of the variable that denotes the number of distinct values is not constrained at all. In the context of the K_ALLDIFFERENT constraint, bound-consistency is only achieved when we have two overlapping ALLDIFFERENT constraints, see [80] for more details.
3.7.39  ▼Business rules ➔  [3 CONS]

- CYCLE,
- DIFFN,
- GEOST.

Denotes that a dedicated language was introduced within an argument of a global constraint for directly specifying a specific type of business rules:

- The CYCLE constraint was extended in order to accept rules specifying forbidden sequences of vertices within each cycle [93].
- The DIFFN constraint was extended in order to accept calendar rules specifying the way tasks can be interrupted or not on each resource [26]. This was done since many real scheduling problems have not only to consider disjunctive and assignment constraints, but also operational rules expressing how tasks can be interrupted.
- The GEOST constraint was extended in order to directly accept a great variety of packing and placement rules [107].

3.7.40  ▼Centered cyclic(1) constraint network(1) ➔  [9 CONS]

- BETWEEN_MIN_MAX,
- DOMAIN_CONSTRAINT,
- IN,
- MAXIMUM,
- MINIMUM,
- MINIMUM_EXCEPT_0,
- NOT_IN,
- OPEN_MAXIMUM,
- OPEN_MINIMUM.

A constraint network corresponding to the pattern depicted by Figure 3.10. Circles depict variables, while arcs are represented by a set of variables. Grey circles correspond to optional variables. All pairs of constraints have at most one variable in common.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.41 ▼Centered cyclic(2) constraint network(1) ➞ [8 CONS]

• ELEM,
• ELEMENT,
• ELEMENT_GREATEREQ,
• ELEMENT_LESSEQ,
• ELEMENT_SPARSE,
• INSAME_PARTITION,
• MINIMUM_GREATER_THAN,
• STAGE_ELEMENT.

A constraint network corresponding to the pattern depicted by Figure 3.11. Circles depict variables, while arcs are represented by a set of variables. Grey circles correspond to optional variables.
3.7.42 Centered cyclic(3) constraint network

- ELEMENT_MATRIX,
- NEXT_ELEMENT.

![Hypergraph](image)

Figure 3.12: Hypergraph associated with a centered cyclic(3) constraint network

A constraint network corresponding to the pattern depicted by Figure 3.12. Circles depict variables, while arcs are represented by a set of variables. Grey circles correspond to optional variables.

3.7.43 Channel routing

- CONNECT_POINTS.

A constraint that can be used for modelling channel routing problems. Channel routing consists of creating a layout in a rectangular region of a VLSI chip in order to link together the terminals of different modules of the chip. Connections are usually made by wire segments on two different layers: horizontal wire segments on the first layer are placed along lines called tracks, while vertical wire segments on the second layer connect terminals to the horizontal wire segments, with vias at the intersection.
3.7.44 Channelling constraint

- CALENDAR,
- DOMAIN_CONSTRAINT,
- INVERSE,
- INVERSE_EXCEPT_LOOP,
- INVERSE_OFFSET,
- INVERSE_SET,
- INVERSE_WITHIN_RANGE,
- LINK_SET_TO_BOOLEANS,
- SAME.

Constraints that allow for linking two models of the same problem [223]. Usually channelling constraints show up in the following context:

- When a problem can be modelled by using different types of variables (e.g., 0-1 variables, domain variables, set variables),

- When a problem can be modelled by using two distinct matrices of variables representing the same information redundantly,

- When, in a problem, the roles of the variables and the values can be interchanged. This is typically the case when we have a bijection between a set of variables and the values they can take.

- When, in a problem, we use two time coordinates systems (e.g., see CALENDAR).

3.7.45 Circuit

- BALANCE_CYCLE,
- CIRCUIT,
- CUTSET,
- CYCLE,
- PROPER_CIRCUIT,
- SYMMETRIC_ALLDIFFERENT,
- SYMMETRIC_ALLDIFFERENT_LOOP.

A constraint such that its initial or its final graph corresponds to zero (e.g., CUTSET), one (e.g., CIRCUIT) or several (see, e.g., the CYCLE, and SYMMETRIC_ALLDIFFERENT constraints) vertex-disjoint circuits.
3.7.46 Circular sliding cyclic(1) constraint network(2) ⇒ [1 CONS]

- CIRCULAR,CHANGE.

A constraint network corresponding to the pattern depicted by Figure 3.13. Circles depict variables, while arcs are represented by a set of variables.

![Hypergraph corresponding to a circular sliding cyclic(1) constraint network(2), where the two red circles correspond to the same variable](image)

Figure 3.13: Hypergraph corresponding to a circular sliding cyclic(1) constraint network(2), where the two red circles correspond to the same variable

3.7.47 Cluster ⇒ [1 CONS]

- CIRCUIT,CLUSTER.

A constraint that partitions the vertices of an initial graph into several clusters.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

### 3.7.48 ▼Coloured ➤

- ASSIGN_AND_COUNTS,
- COLOURED_CUMULATIVE,
- COLOURED_CUMULATIVES,
- CYCLE_CARD_ON_PATH,
- INTERVAL_AND_COUNT.

A constraint with a collection where one of the attributes is a colour.

### 3.7.49 ▼Compulsory part ➤

- COLOURED_CUMULATIVE,
- COLOURED_CUMULATIVES,
- CUMULATIVE,
- CUMULATIVE_CONVEX,
- CUMULATIVE_PRODUCT,
- CUMULATIVE_TWO_D,
- CUMULATIVES,
- DIFFN,
- DISJUNCTIVE.

A constraint for which the filtering algorithm may use the notion of *compulsory part*. The notion of *compulsory part* was introduced by A. Lahrichi within the context of cumulative scheduling problems [259], [261], [260] as well as within the context of rectangles placement problems [262]. Within these two contexts, the *compulsory part* respectively corresponds to the intersection of all feasible instances of a task or to the intersection of all feasible instances of a rectangle.

Figure 3.14 illustrates the notion of *compulsory part* in the context of scheduling and placement problems. The first, second and third rows respectively correspond to the CUMULATIVE [1], the CUMULATIVE_TRAPEZE [330, 331] and the DIFFN [50] constraints. The first, second and third columns respectively correspond to the shape of the object for which we compute the compulsory part, to the extreme positions of the object and to the corresponding compulsory part. When both, the shape of an object is convex and the domain of its origin is also convex, we do not need to consider all feasible instances of the object to compute its compulsory part. We only need to position the object to the extreme positions of its domain and to compute the intersection to get its compulsory part [50].

- This is the case of the CUMULATIVE constraint where a task is positioned to its earliest and latest starts $s_{\text{min}}$ and $s_{\text{max}}$ (see the first row and second column of Figure 3.14).
### 3. DESCRIPTION OF THE CATALOGUE

<table>

<tr>
<td>TRAPEZE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DIFFN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Figure 3.14: Illustration of the notion of compulsory part**

- This is also the case of the DIFFN constraint where an orthotope is positioned to its $2 \cdot n$ extreme positions, where $n$ is the number of dimensions of the placement space (see the third row and second column of Figure 3.14, where the origin of the rectangle is fixed to the extreme positions $(s_{x_{\min}}, s_{y_{\min}})$, $(s_{x_{\max}}, s_{y_{\min}})$, $(s_{x_{\min}}, s_{y_{\max}})$, and $(s_{x_{\max}}, s_{y_{\max}})$).

- But this is not the case of the CUMULATIVE.TRAPEZE constraint with a task that has a valley, i.e. a task for which a resource consumption decrease is followed by a resource consumption increase. In addition of computing the intersection between the two extreme positions $I_{\min}$ and $I_{\max}$ of a task, we must also consider the valleys to further reduce $I_{\min} \cap I_{\max}$ as explained now [331, page 250]. The end of a valley is the lowest rightmost point of a valley. We must remove from $I_{\min} \cap I_{\max}$ all parts that are located both (1) between the earliest start and latest end of the valley end, (2) and on top of the valley. Figure 3.15 illustrates this point for the task used in the second row and first column of Figure 3.14.
Figure 3.15: Illustrating the computation of the compulsory part of a task with a valley: (A) the task shape and its valley end in red, (B) in cyan the intersection between the task positioned at its earliest start (in dashed) and its latest start (in dotted); in pink the part located (1) between the earliest and latest positions of the valley end, and (2) on top of the valley, (C) the compulsory part of the task, i.e., $I_{\text{min}} \cap I_{\text{max}}$ from which we remove the pink part on top of the valley.

### 3.7.50 **Conditional constraint** [2 CONS]

- `SIZE_MAX_SEQ_ALLDIFFERENT`,
- `SIZE_MAX_STARTING_SEQ_ALLDIFFERENT`.

A constraint that allows for expressing that some constraints can be enforced during the enumeration phase.

### 3.7.51 **Configuration problem** [1 CONS]

- `ELEMENT_PRODUCT`.

A constraint that was used for modelling configuration problems. Within the context of configuration problems [411], it is crucial to identify all variable-value pairs which do not participate to any solution. This stems from the fact that one wants typically to avoid proposing invalid choices to the user of such configuration systems.

Note also that open constraints are also useful in the context of configuration problems.
3. DESCRIPTION OF THE CATALOGUE

3.7.52  ▶Connected component ◀

- ALLDIFFERENT_ON_INTERSECTION,
- BALANCE_CYCLE,
- BALANCE_PATH,
- BALANCE_TREE,
- BINARY_TREE,
- CHANGE_CONTINUITY,
- CONNECTED,
- CYCLE,
- CYCLE_CARD_ON_PATH,
- CYCLE_RESOURCE,
- GLOBAL_CONTIGUITY,
- GROUP,
- K_CUT,
- MAP,
- NVALUE_ON_INTERSECTION,
- PATH,
- PROPER_FOREST,
- TEMPORAL_PATH,
- TREE,
- TREE_RANGE,
- TREE_RESOURCE.

Denotes that a constraint uses in its definition a graph property (e.g., MAX_NCC, MIN_NCC, NCC) constraining the connected components of its associated final graph.

3.7.53  ▶Consecutive loops are connected ◀

- GROUP,
- STRETCH_PATH,
- STRETCH_PATH_PARTITION.

Denotes that the graph constraints of a global constraint use only the PATH and the LOOP arc generators and that their final graphs do not contain consecutive vertices that are not connected together by an arc. Moreover all vertices of their final graphs have a loop.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.54 ▶Consecutive values ➔ [3 CONS]

- MaxSize_set_of_consecutive_var,
- MinSize_set_of_consecutive_var,
- Nset_of_consecutive_values.

A constraint for which the definition involves the notion of consecutive values assigned to the variables of a collection of domain variables.

3.7.55 ▶Constraint between two collections of variables ➔ [36 CONS]

- AllDifferent_on_intersection,
- Common,
- Common_interval,
- Common_modulo,

- STRONGLY_CONNECTED
- SUBGRAPH_ISOMORPHISM
- SUM_FREE
- SUM_SET
- SYMMETRIC
- SYMMETRIC_CARDINALITY
- SYMMETRIC_GCC
- TOUR

A constraint involving set variables in its arguments.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.58 ▶ Constraint on the intersection ▶ [4 CONS]

- COMMON,
- ALLDIFFERENT_ON_INTERSECTION,
- NVALUE_ON_INTERSECTION,
- SAME_INTERSECTION.

Denotes that a constraint involving two collections of variables imposes a restriction on the values that occur in both collections.

3.7.59 ▶ Constructive disjunction ▶ [5 CONS]

- CASE,
- DISJUNCTIVE,
- DIFFN,
- GEOST,
- TWO_ORTH_DO_NOT_OVERLAP.

A constraint for which a filtering algorithm uses constructive disjunction. Constructive disjunction [431, 454] is a technique for handling in an active way a set of disjunctive constraints. It consists to try out each alternative of a disjunction and then to remove values that were pruned in all alternatives. Table 3.10 illustrates this technique in the context of a non-overlapping constraint between two rectangles (i.e., a special case of the TWO_ORTH_DO_NOT_OVERLAP constraint). The first rectangle $R_1$ has a width of 3 and a height of 2, while the second rectangle $R_2$ has a width of 2 and a height of 5. The coordinates $(x_1, y_1)$ of the lower leftmost corner of $R_1$ have to be respectively located within intervals $[3, 5]$ and $[6, 7]$. Similarly the coordinates $(x_2, y_2)$ of the lower leftmost corner of $R_2$ have to be located within $[2, 4]$ and $[3, 4]$.

- In the context of the CASE constraint, constructive disjunction is applied on each sink node of the dag describing the set of solutions (i.e., we remove values that are removed in all the sink nodes).

- In the context of the DISJUNCTIVE (respectively DIFFN) constraint, constructive disjunction can be applied on each pair of tasks (respectively objects). However, as described in the Algorithm slots of these two constraints, more specific and efficient filtering algorithms exist for both constraints.

- In the context of the GEOST constraint, constructive disjunction is applied on the different potential values of the shape variable of an object in order to prune its coordinates.
Table 3.10: Illustrating constructive disjunction in the context of a non-overlapping constraint between two rectangles.

<table>
<thead>
<tr>
<th>Hypothesis regarding the respective position of ( R_1 ) and ( R_2 )</th>
<th>( R_2 ) before ( R_1 ): ( X_2 + 2 \leq X_1 )</th>
<th>( R_2 ) after ( R_1 ): ( X_1 + 3 \leq X_2 )</th>
<th>( R_2 ) below ( R_1 ): ( Y_2 + 5 \leq Y_1 )</th>
<th>( R_2 ) on top of ( R_1 ): ( Y_1 + 2 \leq Y_2 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( [2, 4] + 2 \leq [3, 5] ) ( [2, 3] + 2 \leq [4, 5] )</td>
<td><strong>contradiction</strong></td>
<td><strong>contradiction</strong></td>
<td><strong>contradiction</strong></td>
<td><strong>contradiction</strong></td>
</tr>
</tbody>
</table>

Removed values from each variable according to each hypothesis:

\( X_1 : \{3\} \) \( X_2 : \{4\} \) \( Y_1 : \emptyset \) \( Y_2 : \emptyset \)

\( X_1 : \{3, 4, 5\} \) \( X_2 : \{2, 3, 4\} \) \( Y_1 : \{6, 7\} \) \( Y_2 : \{3, 4\} \)

Values finally removed: value 3 from \( X_1 \) and value 4 from \( X_2 \)

3.7.60 Contact

- **ORTH\_ARE\_CONNECTED**,  
- **TWO\_ORTH\_ARE\_IN\_CONTACT**.

A constraint enforcing that some orthotopes touch each other. Part (A) of Figure 3.16 shows two orthotopes that are in contact while parts (B) and (C) give two examples of orthotopes that are not in contact.

![Illustration of contact](image)

(A) (B) (C)

A **contractible** constraint is a constraint for which, given any satisfied ground instance, one can remove any item from one of its collection arguments, without affecting that the resulting constraint still holds, assuming all its restrictions hold. A typical example of a contractible constraint is the **ALLDIFFERENT** constraint: given any ground satisfied instance, e.g., **ALLDIFFERENT**([3, 8, 1]), we can remove any value from its unique argument without affecting that the resulting constraint still holds. We generalise slightly the original definition of contractibility introduced by [283] in the following ways:

- The sequence of variables is replaced by a collection. Consequently, variables are replaced by items. For example, in the context of the **CUMULATIVE**(TASKS, LIMIT) constraint, we can remove any task from TASKS from any satisfied instance without affecting that the resulting constraint still holds (e.g., if the resource limit LIMIT is not exceeded at any point in time, this still is the case if we remove any task, i.e., since task heights are restricted to be non negative).

- Since the constraint may have **more than one argument**, one has to explicitly specify the argument from which one may remove items.

- Items cannot only be removed from the end of a collection like in [283], but also from the beginning or from any part. Allowing to remove items from the beginning is called **prefix-contractibility**, while permitting to re-
move items from the end is called suffix-contractibility. Removing items from any part is just called contractibility. As an example, consider the AMONG_SEQ(LOW, UP, SEQ, VARIABLES, VALUES) constraint which forces all sequences of SEQ consecutive variables of the collection VARIABLES to be assigned at least LOW and at most UP values from VALUES. The constraint AMONG_SEQ is not contractible w.r.t. the collection VARIABLES, since removing an item in the middle of VARIABLES creates a new sequence for which the restriction with respect to LOW and UP may not hold. However, if we restrict ourselves to removing just a prefix or suffix from VARIABLES, then the corresponding AMONG_SEQ constraint still holds, since no new sequence is created.

- A constraint may be contractible only if certain restrictions apply to some of its arguments. This is done by explicitly providing a list of restrictions, each restriction corresponding to one of the restrictions described in Section 2.2.3. We call this conditional contractibility. Given a source and a target constraint (i.e., the target constraint corresponds to the source constraint from which we remove some items in some arguments) all arguments of the target constraint should be identical to the arguments of the source constraint, except:

  - Argument corresponding to a collection from which we remove items.
  - Argument arg occurring in the list of conditional restrictions with of restriction of the form arg = f(|c|), where c is an argument corresponding to a collection from which we remove items and f a function.

In addition, all restrictions from the list of restrictions should apply both to the source and target constraints.

We now provide two examples of conditional contractibility with respect to the AMONG(NVAR, VARIABLES, VALUES) constraint, which forces NVAR to be the number of variables of the collection VARIABLES that are assigned a value in VALUES.

- In general AMONG is not contractible since removing an item from VARIABLES may change the value of NVAR. However, given a ground satisfied instance for which NVAR is set to 0, we can remove any item from VARIABLES without affecting that the constraint still holds. In this context, the two arguments NVAR and VALUES are left unchanged within the source and the target constraint.

  As an illustration, consider the source constraint AMONG(0, (2, 4, 2), (1, 5)) and the target constraint AMONG(0, (2, 2), (1, 5)). Since NVAR is set to 0 both in the source and the target constraint and since VALUES is set to the same list of values both in the source and the target constraint, we have that AMONG(0, (2, 4, 2), (1, 5)) implies AMONG(0, (2, 2), (1, 5)).

- Similarly, when NVAR is equal to |VARIABLES|, all variables are assigned a value in VALUES. In this context, we can remove any variable from
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

VARIABLES to get a new constraint that still holds, provided that the restriction \( \text{NVAR} = |\text{VARIABLES}| \) still holds. In this example only the argument \( \text{VALUES} \) is left unchanged between the source and the target constraint. \( \text{NVAR} \) changes since it occurs in a restriction of the form \( \text{NVAR} = |\text{VARIABLES}| \) in the list of conditional restrictions.

As an illustration, consider the source constraint \( \text{AMONG}(3, \langle 2, 4, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \) and the target constraint \( \text{AMONG}(2, \langle 4, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \). Since \( \text{NVAR} \) is set to the number of items of the \( \text{VARIABLES} \) collection both in the source and the target constraint, and since \( \text{VALUES} \) is set to the same list of values both in the source and the target constraint, we have that \( \text{AMONG}(3, \langle 2, 4, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \) implies \( \text{AMONG}(2, \langle 4, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \).

- Finally, a last extension corresponds to the fact the sequence of variables from which we remove elements may be replaced by several collections. In this context, items are removed simultaneously from all collections from exactly the same set of positions. A set of collections is either defined by a list of collections, or by a collection and one of its attributes, which is itself a collection.

As a first example, consider the \( \text{LEX\_GREATEREQ}(\text{VECTOR1}, \text{VECTOR2}) \) constraint, which gives two vectors each defined by a collection of variables of the same length, forces that \( \text{VECTOR1} \) is lexicographically greater than or equal to \( \text{VECTOR2} \). We have that \( \text{LEX\_GREATEREQ} \) is suffix-contractible with respect to \( \text{VECTOR1} \) and \( \text{VECTOR2} \). This means that we can remove the \( k \) (\( 1 \leq k \leq |\text{VECTOR1}| \)) last items from collections \( \text{VECTOR1} \) and \( \text{VECTOR2} \). Note that the \( k \) items should be removed from both collections simultaneously. As an illustration, consider the source constraint \( \text{LEX\_GREATEREQ}(\langle 5, 2, 8, 9 \rangle, \langle 5, 2, 6, 2 \rangle) \) and the target constraint \( \text{LEX\_GREATEREQ}(\langle 5, 2, 8 \rangle, \langle 5, 2, 6 \rangle) \). Since \( \text{LEX\_GREATEREQ} \) is suffix-contractible with respect to the two collections \( \text{VECTOR1} \) and \( \text{VECTOR2} \), we have that \( \text{LEX\_GREATEREQ}(\langle 5, 2, 8, 9 \rangle, \langle 5, 2, 6, 2 \rangle) \) implies \( \text{LEX\_GREATEREQ}(\langle 5, 2, 8 \rangle, \langle 5, 2, 6 \rangle) \).

As a second example, consider the \( \text{LEX\_CHAIN\_LESSEQ}(\text{VECTORS}) \) constraint, which given a collection of vectors each of them defined by a collection of variables of the same length, forces the \( i^{th} \) vector to be lexicographically less than or equal to the \( (i + 1)^{th} \) vector (\( 1 \leq i < |\text{VECTORS}| \)). We have that \( \text{LEX\_CHAIN\_LESSEQ} \) is suffix-contractible with respect to \( \text{VECTORS.vec} \). This means that we can remove the \( k \) last components of each vectors of the \( \text{VECTORS} \) collection. As in the previous example the \( k \) items should be removed from all collections simultaneously.

As an illustration, consider the source constraint \( \text{LEX\_CHAIN\_LESSEQ}(\langle \text{vec} - \langle 5, 2, 3, 9 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle \rangle) \) and the target constraint \( \text{LEX\_CHAIN\_LESSEQ}(\langle \text{vec} - \langle 5, 2, 3 \rangle, \text{vec} - \langle 5, 2, 6 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle \rangle) \). Since \( \text{LEX\_CHAIN\_LESSEQ} \) is suffix-contractible with respect to \( \text{VECTORS.vec} \), we have that \( \text{LEX\_CHAIN\_LESSEQ}(\langle \text{vec} - \langle 5, 2, 3, 9 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle \rangle) \) implies \( \text{LEX\_CHAIN\_LESSEQ}(\langle \text{vec} - \langle 5, 2, 3 \rangle, \text{vec} - \langle 5, 2, 6 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle \rangle) \) implies \( \text{LEX\_CHAIN\_LESSEQ}(\langle \text{vec} - \langle 5, 2, 3 \rangle, \text{vec} - \langle 5, 2, 6 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle \rangle) \).
The keyword extensible introduces a dual notion, where items can be added to a collection that is passed as an argument of a satisfied global constraint without affecting the fact that the resulting constraint is satisfied. Contractibility is a more common property than extensibility.

3.7.62 Convex

- CUMULATIVE_CONVEX,
- GLOBAL_CONTIGUITY.

A constraint involving the notion of convexity. A subset \( S \) of the plane is called convex if and only if for any pair of points \( p, q \) of this subset the corresponding line segment is contained in \( S \). Part (A) of Figure 3.17 gives an example of convex set, while part (B) depicts an example of non-convex set.

Figure 3.17: (A) A convex set and (B) a non-convex set
3.7. KeyWords Attached to the Global Constraints

3.7.63 Convex bipartite graph

- ALLDIFFERENT,
- ALLDIFFERENT_CST,
- NVALUE.

Denotes that, for a given constraint, its filtering algorithm can take advantage of having a convex bipartite graph. A bipartite graph $G = (U, V, E)$ is called convex according to its second set of vertices $V$ if there is an ordering on $V$ such that, for any vertex $u$ of $U$, the neighbours of $u$ form an interval in the previous ordering. Some graph algorithms or some problems become simpler in the context of a convex bipartite graph.

3.7.64 Convex hull relaxation

- SUM.

Given a non-convex set $S$, $R$ is a convex outer approximation of $S$ if:

- $R$ is convex,
- If $s \in S$, then $s \in R$.

Given a non-convex set $S$, $R$ is the convex hull of $S$ if:

- $R$ is a convex outer approximation of $S$,
- For every $T$ where $T$ is a convex outer approximation of $S$, $R \subseteq T$.

Part (A) of Figure 3.18 depicts a non-convex set, while part (B) gives its corresponding convex hull.

![Figure 3.18: (B) Convex hull of a (A) non-convex set](image-url)
Within the context of linear programming, the convex hull relaxation of a non-convex set $S$ corresponds to the set of linear constraints characterising the convex hull of $S$.

### 3.7.65 Conway packing problem

- **DIFFN.**
- **GEOST.**

Denotes that a constraint can be used for solving the Conway packing problem, which consists of placing 6 orthotopes of size $4 \times 2 \times 1$, 6 orthotopes of size $3 \times 2 \times 2$ and 5 unit cubes within a $5 \times 5 \times 5$ cube. Figure 3.19 shows a solution to the Conway packing problem.

![Figure 3.19: A solution to the Conway packing problem](image-url)
Denotes that a global constraint is an important constraint. In fact many constraints can be seen as variations or extensions around one of the following notions:

- The notion of all different forces a set of domain variables to be assigned distinct values. Given a set of domain variables \( \{v_1, v_2, \ldots, v_n\} \), the \texttt{ALLDIFFERENT}\((v_1, v_2, \ldots, v_n)\) imposes such a condition. For example, the ground instance \texttt{ALLDIFFERENT}\((3, 8, 2, 1)\) is satisfied, while \texttt{ALLDIFFERENT}\((1, 8, 2, 1)\) is not, since value 1 is assigned twice.

- The notion of functional dependency states that a domain variable depends directly of another domain variable. A functional dependency can either be defined in intention or in extension.
  - On the one hand, functional dependencies defined by intension are usually associated with numerical constraints such as, for example, \texttt{ABS\_VALUE}\((y, x)\) which forces the condition \( y = |x| \). They can also be associated with global constraints that mention a characteristic that is computed from one or several collections of variables. This is the case, for example, for the \texttt{NVALUE}\((y, \langle x_1, x_2, \ldots, x_n \rangle)\) constraint which forces \( y \) to be equal to the number of distinct values assigned to \( x_1, x_2, \ldots, x_n \).
  - On the other hand, functional dependencies defined by extension are more general since they allow representing any kind of functional dependency. The \texttt{ELEMENT}\((x, t, y)\) constraint allows expressing that a variable \( y \) is determined by a variable \( x \) via a table of integers \( t \), i.e., \( y = t[x] \). For example, the ground instance \texttt{ELEMENT}\((2, \langle 3, 8, 3, 1 \rangle, 8)\) is satisfied since 8 is equal to the second entry of the table 3, 8, 3, 1. Typical usages of the \texttt{ELEMENT} constraint are, for example:
    * Representing a numerical constraint that is not available in a solver, e.g. a non-linear constraint like \( y = x^3 \) (see first item of the \texttt{Usage} slot of the \texttt{ELEM} constraint).
    * Expressing the link between a discrete choice and its corresponding choice (see second item of the \texttt{Usage} slot of the \texttt{ELEM} constraint).

Both, the \texttt{ELEMENT} and the \texttt{ALLDIFFERENT} constraints, are the most commonly used global constraints. Many core global constraints can be seen as an extension of the \texttt{ALLDIFFERENT}\((x_1, x_2, \ldots, x_n)\) constraint along one of the two following lines:
3. DESCRIPTION OF THE CATALOGUE

ALLDIFFERENT\((\langle 3, 2, 4, 1 \rangle)\)

- enforcing all values to be pairwise distinct

NVALUE\((4, \langle 3, 2, 4, 1 \rangle)\)

- counting the number of distinct values
  - 4 distinct values

CYCLE\((2, \langle 3, 2, 4, 1 \rangle)\)

- counting the number of cycles of a permutation
  - a permutation with 2 cycles \((1, 3, 4)(2)\)

GCC\((\langle 3, 2, 4, 1 \rangle, 1, 2, 1, 3, 1, 4, 1)\)

- counting the number of occurrences of each value
  - values 1, 2, 3 and 4 have a single occurrence

Figure 3.20: Three counting based generalisations of the ALLDIFFERENT constraint: the NVALUE, the CYCLE and the GLOBAL_CARDINALITY (i.e., GCC) constraints; the same example ALLDIFFERENT\((\langle 3, 2, 4, 1 \rangle)\) is reinterpreted with respect to the three generalisations
In the first line we replace the fact that each value should not be used more than once by some more involved counting constraints like:

- Counting the total number of actually used distinct values like the $\text{NVALUE}(y, \langle x_1, x_2, \ldots, x_n \rangle)$ constraint which forces $y$ to be be equal to the number of distinct values assigned to $x_1, x_2, \ldots, x_n$. When $y$ is set to the total number of variables, i.e. $y = n$, $\text{NVALUE}(n, \langle x_1, x_2, \ldots, x_n \rangle)$ and $\text{ALLDIFFERENT}(\langle x_1, x_2, \ldots, x_n \rangle)$ are equivalent.

- Counting the number of cycles of a permutation, i.e. we assume that the values assigned to variables $x_1, x_2, \ldots, x_n$ belong to interval $[1, n]$, like the $\text{CYCLE}(y, \langle x_1, x_2, \ldots, x_n \rangle)$ constraint. When (1) $y$ is unconstrained, i.e. it can take any value in $[1, n]$, and when (2) all variables $x_1, x_2, \ldots, x_n$ belong to $[1, n]$, $\text{CYCLE}(y, \langle x_1, x_2, \ldots, x_n \rangle)$ and $\text{ALLDIFFERENT}(\langle x_1, x_2, \ldots, x_n \rangle)$ are equivalent.

- Counting the number of occurrences of each assigned value like the $\text{GLOBAL_CARDINALITY}(\langle x_1, x_2, \ldots, x_n \rangle, \langle v_1, o_1, v_2, o_2, \ldots, v_m, o_m \rangle)$ constraint, which forces each value $v_i$ ($1 \leq i \leq m$) to be assigned to exactly $o_i$ variables of $x_1, x_2, \ldots, x_n$. When (1) all the occurrence variables $o_1, o_2, \ldots, o_m$ are 0-1 variables, and when (2) all variables $x_1, x_2, \ldots, x_n$ can only be assigned values in $\{v_1, v_2, \ldots, v_m\}$, $\text{GLOBAL_CARDINALITY}(\langle x_1, x_2, \ldots, x_n \rangle, \langle v_1, o_1, v_2, o_2, \ldots, v_m, o_m \rangle)$ and $\text{ALLDIFFERENT}(\langle x_1, x_2, \ldots, x_n \rangle)$ are equivalent. When in addition (3) $m = n$ and $o_i = 1$ for all $i$ we have a bijection between variables and values.

In the second line we generalise the disequality between two variables in some way like:

- We replace the disequality between two variables by a non-overlapping condition between two tasks where a task $t_i$ is defined by its origin $o_i$ and its duration $d_i$. The disequality between two variables is changed to a disjunction stating that a task ends before the start of another task or vice versa. This leads to the $\text{DISJUNCTIVE}(\langle o_1, d_1, o_2, d_2, \ldots, o_n, d_n \rangle)$ constraint.

- We replace the disequality between two variables by a non-overlapping condition between two orthotopes where each orthotope $orth_i$ is defined by the coordinates of its origin and by its sizes. Two orthotopes do not overlap if there exists at least one dimension where their projections do not overlap, i.e. the disequality between two variables is changed to a disjunction with a number of alternatives that is equal to two times the number of dimensions. This leads to the $\text{DIFFN}$ constraint.

- We replace
  * a variable of the $\text{ALLDIFFERENT}$ constraint by a task with a start, a duration, an end and a height attributes, and
  * the disequality between two variables by the condition that the sum of the heights of the tasks that overlap a given time point should not exceed a given limit.
This leads to the **CUMULATIVE** constraint.

### 3.7.67 ▼ Costas arrays ▶

- **ALLDIFFERENT.**

A constraint that allows for expressing the Costas arrays problem. A Costas array is a permutation $p_1, p_2, \ldots, p_n$ of $n$ integers $1, 2, \ldots, n$ such that $\forall \delta \in [1, n - 2], \forall i \in [1, n - \delta - 1], \forall j \in [i + 1, n - \delta] : p_i - p_{i+\delta} \neq p_j - p_{j+\delta}$. A. Vellino compares in [441] three approaches respectively using Prolog, Pascal and CHIP for solving the Costas arrays problem. In fact the weaker formulation $\forall \delta \in [1, \lfloor \frac{n-1}{2} \rfloor], \forall i \in [1, n - \delta - 1], \forall j \in [i + 1, n - \delta] : p_i - p_{i+\delta} \neq p_j - p_{j+\delta}$ was shown to be equivalent to the original one in [119].

### 3.7.68 ▼ Cost filtering constraint ▶

- **COND_LEX_COST,**
- **GLOBAL_CARDINALITY_WITH_COSTS,**
- **SUM_OF_WEIGHTS_OF_DISTINCT_VALUES,**
- **MINIMUM_WEIGHT_ALLDIFFERENT,**
- **WEIGHTED_PARTIAL_ALLDIFF.**

A constraint that has a set of decision variables as well as a cost variable and for which there exists a filtering algorithm that restricts the state variables from the minimum or maximum value of the cost variable.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

### 3.7.69 ▼Cost matrix ➤

- `GLOBAL_CARDINALITY_WITH_COSTS`
- `MINIMUM_WEIGHT_ALLDIFFERENT`

A constraint for which a first argument corresponds to a collection of variables `Vars`, a second argument to a cost matrix `M`, and a third argument to a cost variable `C`. Let `Vals` denotes the set of values that can be assigned to the variables of `Vars`. The cost matrix defines for each pair `v, u` (`v ∈ Vars, u ∈ Vals`) an elementary cost, which is used for computing `C` when value `u` is assigned to variable `v`.

### 3.7.70 ▼Counting constraint ➤

- `AMONG`
- `AMONG_DIFF_0`
- `AMONG_INTERVAL`
- `AMONG_LOW_UP`

A constraint restricting the number of occurrences of some values (respectively some pairs of values) within a given collection of domain variables (respectively pairs
3. DESCRIPTION OF THE CATALOGUE

of domain variables).

3.7.71  ▼Cumulative longest hole problems  ➞  [1 CONS]

• CUMULATIVE.

A constraint that can use some filtering based on the longest closed and open hole problems \[41\]. We follow the presentation from the previous paper. Before presenting the longest closed open hole scheduling problems, let us first introduce some notation related to the CUMULATIVE(TASKS, LIMIT) constraint that will be used within the context of the longest closed and open hole problems.

Here, TASKS is a collection of tasks, and for a task \( t \in \text{TASKS} \), \( t.\text{origin} \), \( t.\text{duration} \) and \( t.\text{height} \) denote respectively its start, duration and height, while \( \text{LIMIT} \in \mathbb{Z}^+ \) is the height of the resource. The constraint is equivalent to finding an assignment \( s : \text{TASKS} \text{.origin} \rightarrow \mathbb{Z}^+ \) that solves the cumulative placement of TASKS of maximum height LIMIT, i.e.:

\[
\forall i \in \mathbb{Z} : \sigma_s(i) = \text{LIMIT} - P(\text{TASKS}, i) \geq 0
\]

where the coverage \( P(\text{TASKS}, i) \) by TASKS of instant \( i \in \mathbb{Z} \) is:

\[
P(\text{TASKS}, i) = \sum_{t \in \text{TASKS} : t.\text{origin} \leq i < t.\text{origin} + t.\text{duration}} t.\text{height}
\]

We are now in position to define the longest closed and open hole problems. Given a quantity \( \sigma \in \mathbb{Z}^+ \) of slack (i.e. the difference between the available space and the total area of the tasks to place), the longest closed hole problem is to find the largest integer \( l_{\text{cmax}}^{\text{LIMIT}}(\text{TASKS}) \) for which there exists a cumulative placement \( s \) of a subset of tasks \( \text{TASKS}' \subseteq \text{TASKS} \) of maximum height LIMIT, such that the resource area that is not occupied by \( s \) on interval \([0, l_{\text{cmax}}^{\text{LIMIT}}] \) does not exceed the maximum allowed slack value \( \sigma \):

\[
\sum_{i=0}^{l_{\text{cmax}}^{\text{LIMIT}}-1} \sigma_s(i) \leq \sigma.
\]

The longest open hole problem is to find the largest integer \( l_{\text{omax}}^{\text{LIMIT}}(\text{TASKS}) \) for which there exists a cumulative placement \( s \) of a subset of tasks \( \text{TASKS}' \subseteq \text{TASKS} \) of

\[\text{Without loss of generality we assume the earliest start of each task to be greater than or equal to 0.}\]
maximum height \( \text{LIMIT} \) and an interval \([i', i' + l_{\max}^{\text{LIMIT}}]\) \( \subset \mathbb{Z} \) of length \( l_{\max}^{\text{LIMIT}} \), such that the resource area that is not occupied by \( s \) on \([i', i' + l_{\max}^{\text{LIMIT}}]\) does not exceed the maximum allowed slack value \( \sigma \):

\[
\sum_{i = i'}^{i' + l_{\max}^{\text{LIMIT}} - 1} \sigma_s(i) \leq \sigma.
\]

As an example, consider seven tasks of respective size \(11 \times 11, 9 \times 9, 8 \times 8, 7 \times 7, 6 \times 6, 4 \times 4, 2 \times 2\). Part (A) of Figure 3.21 provides a cumulative placement corresponding to the longest open hole problem according to \( \text{LIMIT} = 11 \) and \( \sigma = 0 \). The longest open hole \( l_{\max}^{\text{LIMIT}}\{11 \times 11, 9 \times 9, 8 \times 8, 7 \times 7, 6 \times 6, 4 \times 4, 2 \times 2\} = 17 \) since:

- The task \(8 \times 8\) cannot contribute since a gap of 3 cannot be filled by the unique candidate the task \(2 \times 2\).
- The task \(6 \times 6\) can also not contribute since a gap of 5 cannot be completely filled by the candidates \(4 \times 4\) and \(2 \times 2\).

The longest close hole \( l_{\text{cmax}}^{\text{LIMIT}}\{11 \times 11, 9 \times 9, 8 \times 8, 7 \times 7, 6 \times 6, 4 \times 4, 2 \times 2\} = 15\) it corresponds to the longest time interval on which the resource is saturated by the illustrated placement and such that one bound of the interval does not intersect any tasks.

Second, consider a task of size \(3 \times 2\). Part (B) of Figure 3.21 provides a cumulative placement corresponding to the longest open hole problem according to \( \epsilon = 11 \) and \( \sigma = 20 \). The longest open hole \( l_{\max}^{\text{LIMIT}}\{3 \times 2\} = 2\).

Figure 3.21: Two examples for illustrating the longest open hole problem: (A) a first instance with seven tasks of size \(11 \times 11, 9 \times 9, 8 \times 8, 7 \times 7, 6 \times 6, 4 \times 4, 2 \times 2\) with a slack \( \sigma = 0 \) and a gap of 11, (B) a second instance with a single task of size \(3 \times 2\) with a slack \( \sigma = 20 \) and a gap of 11.

Figure 3.22 provides examples of the longest closed hole when we have 15 squares of sizes \(1, 2, \ldots, 15\) and a zero slack. Parts (A), (B), \ldots, (O) respectively give a solution achieving the longest closed hole for a gap of \(1, 2, \ldots, 15\). For comparison, Figure 3.23 provides the same examples of the longest open hole with zero slack.
Figure 3.22: Given 15 tasks of sizes $1 \times 1, 2 \times 2, \ldots, 15 \times 15$ and a slack $\sigma = 0$, examples of longest closed holes (in red) for a gap of $1, 2, \ldots, 15$
Figure 3.23: Given 15 tasks of sizes $1 \times 1, 2 \times 2, \ldots, 15 \times 15$ and a slack $\sigma = 0$, examples of longest open holes (in red) for a gap of 1, 2, \ldots, 15.
3. DESCRIPTION OF THE CATALOGUE

3.7.72 ▼Cycle ➔

- BALANCE_CYCLE,
- CYCLE,
- SYMMETRIC_ALLDIFFERENT,
- SYMMETRIC_ALLDIFFERENT_LOOP.

A constraint that can be used for restricting the number of cycles of a permutation (i.e., CYCLE), or for restricting the size of the cycles of a permutation (i.e., SYMMETRIC_ALLDIFFERENT, SYMMETRIC_ALLDIFFERENT_LOOP), or for restricting the difference between the largest and the smallest cycle (i.e., BALANCE_CYCLE).

3.7.73 ▼Cyclic ➔

- CIRCULAR_CHANGE,
- CYCLIC_CHANGE,
- CYCLIC_CHANGE_JOKER,
- STRETCH_CIRCUIT.

A constraint that involves a kind of cyclicity in its definition. It either uses the arc generator CIRCUIT or an arc constraint involving \( \text{mod} \).

3.7.74 ▼Data constraint ➔

- ELEM,
- ELEM_FROM_TO,
- ELEMENT,
- ELEMENTN,
- ELEMENT_GREATEREQ,
- ELEMENT_LESSEQ,
- ELEMENT_MATRIX,
- ELEMENT_PRODUCT,
- ELEMENT_SPARSE,
- ELEMENTS,
- ELEMENTS_ALLDIFFERENT,
- ELEMENTS_SPARSE,
- IN_RELATION,
- ITH_POS_DIFFERENT_FROM_0.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

- NEXT\_ELEMENT,
- NEXT\_GREATER\_ELEMENT,
- STAGE\_ELEMENT,
- SUM.

In the literature also known as *ad-hoc constraints*. A constraint that allows for representing an access to an element of a data structure (e.g., a table, a matrix, a relation) or to compute a value from a given data structure.

### 3.7.75 Deadlock breaking

- CUTSET.

A constraint that was used within the application area of *deadlock breaking*.

### 3.7.76 Decomposition

- ALL\_MIN\_DIST,
- ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS,
- ALL\_DIFFER\_FROM\_AT\_MOST\_K\_POS,

- K\_SAME\_INTERVAL,
3. DESCRIPTION OF THE CATALOGUE

- K_SAME_MODULO,
- K_SAME_PARTITION,
- K_USED_BY,
- K_USED_BY_INTERVAL,
- K_USED_BY_MODULO,
- K_USED_BY_PARTITION,
- LEX_ALLDIFFERENT,
- LEX_CHAIN_GREATER,
- LEX_CHAIN_GREATEREQ,
- LEX_CHAIN_LESS,
- LEX_CHAIN_LESSEQ,
- LINK_SET_TO_BOOLEANS,
- ORTH_LINK_ORI_SIZ_END,
- PRECEDENCE,
- ROOTS,
- SEQUENCE_FOLDING,
- SLIDING_DISTRIBUTION,
- SLIDING_SUM,
- STRICTLY_DECREASING,
- STRICTLY_INCREASING,
- SYMMETRIC_CARDINALITY,
- SYMMETRIC_GCC,
- VISIBLE.

A constraint for which the catalogue provides a description in terms of a conjunction of more elementary constraints. This is the case when the constraint is described by one or several graph constraints that all satisfy the following property: the description uses the NARC graph property and forces all arcs of the initial graph to belong to the final graph. Most of the time we have only a single graph constraint. But some constraints (e.g., DIFFN) use more than one. Note that the arc constraint can sometimes be a logical expression involving several constraints (e.g., DOMAIN_CONSTRAINT).

3.7.77 Decomposition-based violation measure ➝ [2 CONS]

- SOFT_ALLDIFFERENT_CTR,
- SOFT_ALL_EQUAL_MIN_CTR.

A soft constraint associated with a constraint that can be described in terms of a conjunction of more elementary constraints for which the violation cost is the number of violated elementary constraints.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.78 • Demand profile ➔

- CUMULATIVES,
- SAME_AND_GLOBAL_CARDINALITY_LOW_UP,
- SAME_AND_GLOBAL_CARDINALITY.

A constraint that allows for representing problems where one has to allocate resources in order to cover a given demand. A profile specifies for each instant the minimum, and possibly maximum, required demand.

3.7.79 • Degree of diversity of a set of solutions ➔

- LEX_CHAIN_GREATER,
- LEX_CHAIN_LESS,
- SOFT_ALLDIFFERENT_CTR.

A constraint that allows finding a set of solutions with a certain degree of diversity. As an example, consider the problem of finding 9 diverse solutions for the 10-queens problem. For this purpose we create a 10 by 9 matrix \( M \) of domain variables taking their values in interval \([0, 9]\). Each row of \( M \) corresponds to a solution to the 10-queens problem. We assume that the variables of \( M \) are assigned row by row, and that within a given row, they are assigned from the first to the last column. Moreover values are tried in increasing order. We first post for each row of \( M \) the 3 ALLDIFFERENT constraints related to the 10-queens problem (see Figure 5.32 for an illustration of the 3 ALLDIFFERENT constraints). With a LEX_CHAIN_LESS constraint, we lexicographically order the first two variables of each row of \( M \) in order to enforce that the first two variables of any pair of solutions are always distinct. We then impose a SOFT_ALLDIFFERENT_CTR constraint on the variables of each column of \( M \). Let \( C_i \) denotes the corresponding cost variable associated with the SOFT_ALLDIFFERENT_CTR constraint of the \( i \)-th column of \( M \) (i.e., the first argument of the SOFT_ALLDIFFERENT_CTR constraint). We put a maximum limit (e.g., 3 in our example) on these cost variables. We also impose that the sum of these cost variables should not exceed a given maximum value (e.g., 8 in our example). Finally, in order to balance the diversity over consecutive variables we state that the sum of two consecutive cost variables should not exceed a given threshold (e.g., 2 in our example). As one of the possible results we get the following nine solutions depicted below.
3. DESCRIPTION OF THE CATALOGUE

- $S_1 = ⟨0, 2, 5, 7, 9, 4, 8, 1, 3, 6⟩$,
- $S_2 = ⟨0, 3, 5, 8, 2, 9, 7, 1, 4, 6⟩$,
- $S_3 = ⟨1, 3, 7, 2, 8, 5, 9, 0, 6, 4⟩$,
- $S_4 = ⟨2, 4, 8, 3, 9, 6, 1, 5, 7, 0⟩$,
- $S_5 = ⟨3, 6, 9, 1, 4, 7, 0, 2, 5, 8⟩$,
- $S_6 = ⟨5, 9, 2, 6, 3, 1, 8, 4, 0, 7⟩$,
- $S_7 = ⟨6, 8, 1, 5, 0, 2, 4, 7, 9, 3⟩$,
- $S_8 = ⟨8, 1, 4, 9, 7, 0, 3, 6, 2, 5⟩$,
- $S_9 = ⟨9, 5, 0, 4, 1, 8, 6, 3, 7, 2⟩$.

The costs associated with the $\text{SOFT\_ALLDIFFERENT\_CTR}$ constraints of columns 1, 2, \ldots, 10 are respectively equal to 1, 1, 1, 0, 1, 0, 1, 1, and 1. The different types of constraints between the previous 9 solutions are illustrated by Figure 3.24. The nine diverse solutions $S_1, S_2, \ldots, S_9$ are shown by Figure 3.25. Figure 3.26 depicts the distribution of all the queens of the nine solutions on a unique chessboard.
Figure 3.24: Constraint network associated with the problem of finding 9 diverse solutions for the 10-queens problem where variables are fixed to the solutions corresponding to $S_1 = \langle 0, 2, 5, 7, 9, 4, 8, 1, 3, 6 \rangle$, $S_2 = \langle 0, 3, 5, 8, 2, 9, 7, 1, 4, 6 \rangle$, ... , $S_9 = \langle 9, 5, 0, 4, 1, 8, 6, 3, 7, 2 \rangle$, and where each type of constraint (hyperedge) is drawn with its own colour.

Approaches for finding diverse and similar solutions based on the Hamming distances between each pair of solutions are presented by E. Hebrard et al. [215].
Figure 3.25: Nine diverse solutions to the 10-queens problem
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

Figure 3.26: Distribution of the queens on the chessboard of the nine diverse solutions depicted by Figure 3.25 to the 10-queens problem: a red queen means two queens from two different solutions that are placed on a same cell, non-red queens of a same colour are queens that belong to a same solution; out of the $10 \times 10$ cells of the original chessboard, $9 \cdot 10 - 2 \cdot 8 = 74$ cells are occupied by a single queen, 8 by two queens, and 18 by no queen at all.
3.7.80  **Derived collection**  

- ASSIGN_AND_COUNTS
- CORRESPONDENCE
- CUMULATIVE_TWO_D
- CUMULATIVE_WITH_LEVEL_OF_PRIORITY
- CUMULATIVES
- CYCLE_RESOURCE
- DOMAIN_CONSTRAINT
- ELEMENT
- ELEMENT_MATRIX
- ELEMENT_SPARSE
- ELEMENTS_SPARSE
- GOLOMB
- IN
- IN_INTERVAL
- IN_RELATION
- INSAME_PARTITION
- LEX_GREATER
- LEX_GREATEREQ
- LEX_LESS
- LEX_LESSEQ
- LINK_SET_TOBOOLEANS
- MINIMUM_GREATER_THAN
- NEXT_ELEMENT
- NEXT_GREATER_ELEMENT
- NOT_IN
- SLIDING_TIME_WINDOW_FROM_START
- SORT_PERMUTATION
- TRACK
- TREE_RESOURCE
- TWO_LAYER_EDGE CROSSING

A constraint that uses one or several derived collections. Derived collections were introduced in Section 2.3.2 on page 51.

3.7.81  **DFS-bottleneck**  

- ALLDIFFERENT (filtering DFS-bottleneck)
- BALANCE_CYCLE (filtering and reformulation DFS-bottleneck)
- BALANCE_PATH (filtering and reformulation DFS-bottleneck)
- BALANCE_TREE (filtering and reformulation DFS-bottleneck)
- BIPARTITE (filtering and reformulation DFS-bottleneck)
- CIRCUIT (filtering and reformulation DFS-bottleneck)
- CYCLE (filtering and reformulation DFS-bottleneck)
- CONNECTED (filtering and reformulation DFS-bottleneck)
- DERANGEMENT (filtering DFS-bottleneck)
- GLOBAL_CARDINALITY (filtering DFS-bottleneck)
- GLOBAL_CARDINALITY_LOW_UP (filtering DFS-bottleneck)
- MAP (filtering and reformulation DFS-bottleneck)
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

- **PATH** (filtering and reformulation DFS-bottleneck),
- **PROPER_CIRCUIT** (filtering and reformulation DFS-bottleneck),
- **SAME** (filtering DFS-bottleneck),
- **TOUR** (filtering and reformulation DFS-bottleneck),
- **TREE** (filtering and reformulation DFS-bottleneck),
- **USED_BY** (filtering DFS-bottleneck).

**reformulation DFS-bottleneck** A constraint on a graph for which a depth-first search based procedure is normally required for checking whether a ground instance is satisfied or not, e.g., a connectivity constraint. The reformulation of such a constraint as a conjunction of other constraints is usually not easy. A possibility, when each node has a single successor in the ground case, is to use an **ELEMENT** constraint to express the link between a node and its successor at the price of using a large number of **ELEMENT** constraints (e.g., see the Reformulation slot of the CYCLE constraint).

**filtering DFS-bottleneck** A constraint for which a depth-first search based algorithm usually constitutes a bottleneck of its filtering algorithm. This is a pity, especially on dense graphs, where most of the invocations of the filtering algorithm do not usually bring any new deductions. Motivated by this fact, randomised filtering algorithms were introduced in [243] and [246] in the context of the **GLOBAL/Cardinality**, **LOW_UP** and **ALLDIFFERENT** constraints. A second approach is to come up with a probabilistic analysis for predicting whether triggering a given filtering algorithm can produce new deductions. This was done for the bound-consistency algorithm of the **ALLDIFFERENT** constraint in [89].

---

11 A common implementation trick relies on the fact that, quite often on dense graphs, a depth-first search algorithm develops a path (rather than a tree) visiting all vertices, such that one can directly reach (i.e., with a single arc) the first node of the path from the last one (i.e., we have a single strongly connected component). In this context the trick is to stop the depth-first search algorithm as soon as the last node of the path is reached, in order to avoid scanning through all remaining arcs of the graph. When this is the case the complexity of the DFS goes from $O(m)$ down to $O(n)$ where $n$ is the number of vertices and where $m$ is the number of arcs of the graph.
3. DESCRIPTION OF THE CATALOGUE

3.7.82 ▼Difference ➦  

- GOLOMB,  
- SUM_OF_INCREMENT.

Denotes that the definition of a constraint involves one or several differences between pairs of variables.

3.7.83 ▼Difference between pairs of variables ➦  

- LEX_ALLDIFFERENT,  
- LEX_ALLDIFFERENT_EXCEPT_0.

A constraint that allows expressing that a set of pairs of variables are different. Two pairs of variables \((X_1, Y_1)\) and \((X_2, Y_2)\) are different if and only if \(X_1 \neq X_2\) or \(Y_1 \neq Y_2\). Constraint LEX_ALLDIFFERENT_EXCEPT_0 ignores pairs for which both components are assigned value 0.

3.7.84 ▼Directed acyclic graph ➦  

- CUTSET.

A constraint that forces the final graph to be a directed acyclic graph. A directed acyclic graph is a digraph with no path starting and ending at the same vertex.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

3.7.85 ▾Disequality ▾

- ALL_DIFFER_FROM_AT_LEAST_K_POS,
- ALL_DIFFER_FROM_AT_MOST_K_POS,
- ALL_DIFFER_FROM_EXACTLY_K_POS,
- ALLDIFFERENT,
- ALLDIFFERENT_BETWEEN_SETS,
- ALLDIFFERENT_CST,
- ALLDIFFERENT_CONSECUTIVE_VALUES,
- DISJOINT,
- ELEMENTS_ALLDIFFERENT,
- GOLOMB,
- K_ALLDIFFERENT,
- K_DISJOINT,
- LEX_DIFFERENT,
- NEQ_CST,
- NOT_ALL_EQUAL,
- NOT_IN,
- OPEN_ALLDIFFERENT,
- PERMUTATION,
- ROOTS,
- SIZE_MAX_STARTING_SEQ_ALLDIFFERENT,
- SIZE_MAX_SEQ_ALLDIFFERENT,
- SOFT_ALLDIFFERENT_CTR,
- SOFT_ALLDIFFERENT_VAR,
- SYMMETRIC_ALLDIFFERENT,
- SYMMETRIC_ALLDIFFERENT_LOOP.

Denotes that a disequality between two domain variables, one domain variable and a fixed value, or two set variables is used within the definition of a constraint. Denotes also that the notion of disequality can be used within the informal definition of a constraint. This is the case, for example, for the relaxation of the ALLDIFFERENT constraint (i.e., SOFT_ALLDIFFERENT_CTR, SOFT_ALLDIFFERENT_VAR), which do not strictly enforce a disequality.
3. DESCRIPTION OF THE CATALOGUE

3.7.86  • Disjunction ➔  [12 CONS]

- CASE,
- ARITH_OR,
- CLAUSE_OR,
- DIFFN,
- DISJUNCTIVE,
- DISJUNCTIVE_OR_SAME_END,
- DISJUNCTIVE_OR_SAME_START,
- ELEMENT,
- ELEM,
- GEOST,
- GEOST_TIME,
- OR.

Denotes that a constraint can be used for modelling some kind of disjunction.

3.7.87  • Domain channel ➔  [1 CONS]

- DOMAIN_CONSTRAINT.

A constraint that allows for making the link between a domain variable \( V \) and a set of 0-1 variables \( B_1, B_2, \ldots, B_n \). It enforces a condition of the form \( V = i \Leftrightarrow B_i = 1 \).

3.7.88  • Domain definition ➔  [6 CONS]

- ARITH,
- DOMAIN,
- IN,
- IN_INTERVAL,
- IN_INTERVALS,
- NOT_IN.

A constraint that is used for defining the initial domain of one or several domain variables or for removing some values from the domain of one or several domain variables.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.89 ▶Dominating queens ◀

- NVALUE.

A constraint that can be used for modelling the dominating queens problem. Place a number of queens on an $n$ by $n$ chessboard in such a way that all squares are either attacked by a queen or are occupied by a queen. A queen can attack all squares located on the same column, on the same row or on the same diagonal. Values of the minimum number of queens for $n$ less than or equal to 120 are reported in [310]. Most of them are in fact either equal to $\lceil \frac{n+1}{2} \rceil$ or to $\lceil \frac{n+1}{2} \rceil + 1$. Values $n = 3$ and $n = 11$ are the only two values below 120 for which the previous assertion is not true since we only need in these two cases $\lfloor \frac{n}{2} \rfloor$ queens.

3.7.90 ▶Domination ◀

- ATLEAST,NVECTOR,
- ATMOST,NVECTOR,
- NVALUE,
- NVECTOR,
- NVECTORS,
- SUM_OF_WEIGHTS_OF_DISTINCT_VALUES.

A constraint that can be used for expressing directly the fact that we search for a dominating set in an undirected graph. Given an undirected graph $G = (V, E)$ where $V$ is a finite set of vertices and $E$ a finite set of unordered pairs of distinct elements from $V$, a set $S$ is a dominating set if for every vertex $u \in V - S$ there exists a vertex $v \in S$ such that $u$ is adjacent to $v$. Part (A) of Figure 3.27 gives an undirected graph $G$, while part (B) depicts a dominating set $S = \{e, f, g\}$ in $G$. 
3. DESCRIPTION OF THE CATALOGUE

Figure 3.27: (A) A graph and (B) one of its dominating set $S = \{e, f, g\}$
3.7.91  ▶Dual model ◀

- INVERSE
- INVERSE_EXCEPT_LOOP
- INVERSE_OFFSET
- INVERSE_SET
- INVERSE_WITHIN_RANGE

A constraint that can be used as a channelling constraint in a problem where the roles of the variables and the values can be interchanged. This is the case, for example, when we have a bijection between a set of variables and the values they can take.

3.7.92  ▶Duplicated variables ◀

- GLOBAL_CARDINALITY
- K_ALLDIFFERENT
- LEX_GREATER
- LEX_GREATEREQ
- LEX_LESS
- LEX_LESSEQ
- SCALAR_PRODUCT
- STRETCH_CIRCUIT

A constraint for which the situation where the same variable can occur more than once was considered in order to derive a better filtering algorithm or to prove a complexity result for achieving arc-consistency. Also in the case of the STRETCH_CIRCUIT constraint, a constraint for which the reformulation duplicates some variables.

3.7.93  ▶Dynamic programming ◀

- [5 CONS]
3. DESCRIPTION OF THE CATALOGUE

• AMONG_SEQ,
• CHANGE,
• CUMULATIVE,
• STRETCH_CIRCUIT,
• STRETCH_PATH.

A constraint for which a filtering algorithm uses dynamic programming. Note that dynamic programming was also used by M. A. Trick within the context of linear constraints [419].

3.7.94 ▼ Empty intersection ➞ [2 CONS]

• DISJOINT,
• K.DISJOINT.

A constraint which forces an empty intersection between two sets of variables.

3.7.95 ▼ Entailment ➞ [6 CONS]

• ALLDIFFERENT,
• AMONG_LOW_UP,
• GLOBAL_CARDINALITY_LOW_UP,
• MAXIMUM,
• MINIMUM,
• NOT_IN.

Denotes that the catalogue mentions a sufficient condition for the entailment of a constraint. Consider a constraint \( C(V_1, V_2, \ldots, V_n) \) and the potential sets of values \( \text{dom}(V_1), \text{dom}(V_2), \ldots, \text{dom}(V_n) \) that can respectively be assigned to the distinct domain variables \( V_1, V_2, \ldots, V_n \). The constraint \( C(V_1, V_2, \ldots, V_n) \) is entailed if and only if \( C(V_1, V_2, \ldots, V_n) \) holds whatever values \( \text{val}_1 \in \text{dom}(V_1), \text{val}_2 \in \text{dom}(V_2), \ldots, \text{val}_n \in \text{dom}(V_n) \) will respectively be assigned variables \( V_1, V_2, \ldots, V_n \). A satisfied constraint for which all variables are already fixed is trivially entailed.
Entailment is usually not considered as very important when designing a filtering algorithm, even though it can sometimes save waking again and again a constraint that will for sure be satisfied. Failure to detect entailment can leads to a memory leak if the constraint system is supposed to reclaim memory for entailed constraints for which it is no more possible to backtrack over the point where the constraint was posted. From a modelling point of view, entailment detection is mandatory for coming up with the reified version of a constraint (see also reified automaton constraint).

3.7.96  ▼ Equality  ➔

- EQSET.

Denotes that the notion of equality can be used within the informal definition of a constraint.

3.7.97  ▼ Equality between multisets  ➔

- KSAME,
- SAME,
- SAME\_AND\_GLOBAL\_CARDINALITY,
- SAME\_AND\_GLOBAL\_CARDINALITY\_LOW\_UP.

A constraint that can be used for modelling an equality constraint between two multisets.
3. DESCRIPTION OF THE CATALOGUE

3.7.98  Equivalence

• ATLEAST_NVALUE,
• ATLEAST_NVECTOR,
• ATMOST_NVALUE,
• ATMOST_NVECTOR,
• BALANCE_INTERVAL,
• BALANCE_MODULO,
• BALANCE_PARTITION,
• BALANCE,
• INCREASING_NVALUE,
• MAX_NVALUE,
• MIN_NVALUE,

• NCLASS,
• NEQUIVALENCE,
• NINTERVAL,
• NOT_ALL_EQUAL,
• NPAIR,
• NVALUE,
• NVALUES,
• NVECTOR,
• NVECTORS,
• SOFT_ALLDIFFERENT_VAR.

Denotes that a constraint is defined by a graph constraint for which the final graph is reflexive, symmetric and transitive.

3.7.99  Euler knight

• ALLDIFFERENT,
• CIRCUIT,

• CYCLE,
• TOUR.

Denotes that a constraint can be used for modelling some parts of the Euler knight problem. The Euler knight problem consists of finding a sequence of moves on a chessboard by a knight such that each square of the board is visited exactly once. While a natural model uses an undirected graph together with the TOUR constraint, the problem is usually modeled with a directed graph that does not require set variables.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.100 Excluded [1 CONS]

- **NOT_IN.**

A constraint that prevents certain values to be taken by a variable.

3.7.101 Extensible [57 CONS]

- **ALL_DIFFER_FROM_AT_LEAST_K_POS** (extensible wrt VECTORS.vec),
- **AND** (extensible wrt VARIABLES when VAR = 0),
- **ASSIGN_AND_COUNTS** (extensible wrt ITEMS when RELOP ∈ [≥, >]),
- **ASSIGN_AND_NVVALUES** (extensible wrt ITEMS when RELOP ∈ [≥, >]),
- **ATLEAST** (extensible wrt VARIABLES),
- **ATLEAST_NVVALUE** (extensible wrt VARIABLES),
- **ATLEAST_NVVECTOR** (extensible wrt VECTORS),
- **BETWEEN_MIN_MAX** (extensible wrt VARIABLES),
- **CLAUSE_AND** (extensible wrt POSVARS when VAR = 0),
- **CLAUSE_AND** (extensible wrt NEGVARS when VAR = 0),
- **CLAUSE_OR** (extensible wrt POSVARS when VAR = 1),
- **CLAUSE_OR** (extensible wrt NEGVARS when VAR = 1),
- **COMPARE_AND_COUNT** (extensible wrt [VARIABLES1, VARIABLES2] when COUNT ∈ [≥, >]),
- **COUNT** (extensible wrt VARIABLES when RELOP ∈ [≥, >]),
- **COUNTS** (extensible wrt VARIABLES when RELOP ∈ [≥, >]),
- **DIFFER_FROM_AT_LEAST_K_POS** (extensible wrt [VARIABLES1, VARIABLES2]),
- **ELEMENT** (suffix-extensible wrt TABLE),
- **ELEMENT_PRODUCT** (suffix-extensible wrt TABLE),
- **ELEMENTN** (suffix-extensible wrt TABLE),
- **IN** (extensible wrt VALUES),
- **IN_INTERVALS** (extensible wrt INTERVALS),
- **IN_RELATION** (extensible wrt TUPLES_OF_VALS),
- **INSAME_PARTITION** (extensible wrt PARTITIONS),
- **ITH_POS_DIFFERENT_FROM_0** (suffix-extensible wrt VARIABLES),
- **LEX_ALLDIFFERENT** (extensible wrt VECTORS.vec),
- **LEX_CHAIN_LESS** (suffix-extensible wrt VECTORS.vec),
- **LEX_DIFFERENT** (extensible wrt [VECTOR1, VECTOR2]),
An extensible constraint is a constraint for which, given any satisfied ground instance (i.e., a source constraint), one can add any item without affecting that the resulting constraint (i.e., a target constraint) still holds, assuming all its restrictions holds. All the extensions of contractibility described at the corresponding keyword entry apply also for extensibility. In particular we also have the restricted notions of prefix-extensible and suffix-extensible constraints, which respectively means that items are added before the first item of a collection or after the last item. As for contractibility, extensibility may also be conditioned by a list of restrictions. Finally extensibility may involve more than one collection. In this context, items are added simultaneously to all collections from exactly the same set of positions. We now present different examples of extensible constraints, starting from a very simple one.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

- As a first example, consider the \textsc{atleast}(N, VARIABLES, VALUE) constraint, which forces at least \( N \) variables of the \textsc{variables} collection to be assigned value \textsc{value}. We have that \textsc{atleast} is \textit{extensible} with respect to \textsc{variables}, since adding a variable to an already satisfied instance of \textsc{atleast} preserves the fact the new constraint is satisfied.

  As an illustration consider the source constraint \textsc{atleast}(2, (4, 2, 4, 5), 4) and the target constraint \textsc{atleast}(2, (4, 2, 4, 5, 0, 4), 4). Since the first argument \( N \) is set to the same value, both in the source and the target constraint, and since the third \textsc{value} is also set to the same value both in the source and the target constraint, we have that \textsc{atleast}(2, (4, 2, 4, 5), 4) implies \textsc{atleast}(2, (4, 2, 4, 5, 0, 4), 4).

- As a second example, consider the \textsc{element}(INDEX, TABLE, VALUE) constraint, which forces \textsc{value} to equal the \textsc{index} \textsc{th} item of \textsc{table}. We have that \textsc{element} is \textit{suffix-extensible} with respect to \textsc{table}, since adding new elements at the end of \textsc{table} for an already satisfied instance of \textsc{element} preserves the fact the new constraint is satisfied.

  As an illustration consider the source constraint \textsc{element}(3, (6, 9, 2, 9), 2) and the target constraint \textsc{element}(3, (6, 9, 2, 9, 8, 0, 2), 2). Since the first argument \textsc{index} is set to the same value, both in the source and the target constraint, and since the third argument \textsc{value} is also set to the same value both in the source and the target constraint, we have that \textsc{element}(3, (6, 9, 2, 9), 2) implies \textsc{element}(3, (6, 9, 2, 9, 8, 0, 2), 2).

- As a third example, consider the \textsc{and}(VAR, VARIABLES) constraint, which forces \textsc{var} to equal 1 if all variables of \textsc{variables} are set to 1, and 0 otherwise. We have that \textsc{and} is \textit{extensible} with respect to \textsc{variables} when \textsc{var} is equal to 0. This stems from the fact that, given a satisfied instance of \textsc{and} where \textsc{var} = 0, adding any new variable to \textsc{variables} preserves the fact the new constraint is satisfied. As an illustration consider the source constraint \textsc{and}(0, (1, 0, 1)) and the target constraint \textsc{and}(0, (1, 0, 1)). Since the first argument \textsc{var} is set to 0, both in the source and the target constraint, we have that \textsc{and}(0, (1, 0, 1)) implies \textsc{and}(0, (1, 0, 1)).

- As a fourth example, consider the \textsc{lex_greater}(VECTOR1, VECTOR2) constraint, which forces \textsc{vector1} to be lexicographically strictly greater than \textsc{vector2}. We have that \textsc{lex_greater} is \textit{suffix-extensible} with respect to \textsc{vector1} and \textsc{vector2}. This means that, given a satisfied instance of \textsc{lex_greater}, adding \( k \) items at the end of its first argument \textsc{vector1} and adding \( k \) other items at the end of its second argument \textsc{vector2} preserves the fact the new constraint is satisfied.

  As an illustration consider the source constraint \textsc{lex_greater}((5, 2, 7, 1), (5, 2, 6, 2)) and the target constraint \textsc{lex_greater}((5, 2, 7, 1, 0), (5, 2, 6, 2, 9)). We have that \textsc{lex_greater}((5, 2, 7, 1), (5, 2, 6, 2)) implies \textsc{lex_greater}((5, 2, 7, 1, 0), (5, 2, 6, 2, 9)).
• As a fifth example, consider the `LEX_CHAIN_LESS(VECTORS)` constraint, which given a collection of vectors each of which defined by a collection of variables of the same length, forces the $i^{th}$ vector to be lexicographically strictly less than the $(i + 1)^{th}$ vector ($1 \leq i < |\text{VECTORS}|$). We have that `LEX_CHAIN_LESS` is suffix-extensible with respect to `VECTORS.vec`. This means that, given a satisfied instance of `LEX_CHAIN_LESS`, adding $k$ items at the end of all collections simultaneously preserves the fact the new constraint is satisfied.

As an illustration consider the source constraint `LEX_CHAIN_LESS((\text{vec} - \langle 5, 2, 3, 9 \rangle, \text{vec} - \langle 5, 2, 6, 2 \rangle, \text{vec} - \langle 5, 2, 6, 3 \rangle)` and the target constraint `LEX_CHAIN_LESS((\text{vec} - \langle 5, 2, 3, 9, 9 \rangle, \text{vec} - \langle 5, 2, 6, 2, 8 \rangle, \text{vec} - \langle 5, 2, 6, 3, 7 \rangle)`. Since each vector of the source constraint is a prefix of the vector located at the same position in the target constraint the source constraint implies the target constraint.

The keyword `contractible` introduces a dual notion, where items can be removed from a collection that is passed as an argument of a satisfied global constraint without affecting the fact that the resulting constraint is satisfied. Contractibility is a more common property than extensibility.

3.7.102  **Extension**  

• `IN_RELATION`.

A constraint that is defined by explicitly providing all its solutions.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.103 Facilities location problem

- CYCLE, OR_ACCESSIBILITY,
- SUM_OF_WEIGHTS_OF_DISTINCT_VALUES.

A constraint that allows for modelling a facilities location problem. In a facilities location problem one has to select a subset of locations from a given initial set so that a given set of conditions holds.

3.7.104 Floor planning problem

- DIFFN,
- GEOST,
- LEX_CHAIN_GREATER,
- LEX_CHAIN_LESS.

A constraint that can be used for the floor planning problem. The floor planning problem involves various type of spaces, such as the placement space itself (i.e., the floor), the rooms to place within the placement space, and the circulation between the rooms. The placement space can be located on a single level or on several levels. Very often the placement space corresponds to a single rectangle and all rooms are rectangles with their borders parallel to the contour of the placement space. Circulation typically corresponds to corridors or stairs that respectively allow to access from one room to another room or from one level to another level. Within the context of floor planning three main classes of constraints have been identified, namely dimensional topological and implicit constraints:

- A dimensional constraint usually restricts the length, the width or the surface of a single space. Ratio constraints enforce aesthetic proportions between the length and the width of a single space or constraint the surfaces of two closely related spaces such as the toilets and the shower. Dimensional constraints can be expressed by reducing the domain of some variable or by stating some arithmetic constraints between two variables.

- A topological constraint imposes a condition between two spaces. Typical topological constraints are:
  - Adjacency constraints with a minimum contact between a room and a corridor or another room allow expressing that there must be enough place to put a door between two given spaces. In the context of staircases one has
to enforce that fact that the first and last stairs are completely accessible. When a corridor is made up from two parts, one also has to enforce that the two parts are fully in contact.

– **Adjacency with the contour constraints** between a room and a specified (or not) side of the contour allow expressing the orientation of a room (or just that a room must have some window).

– **Relative positioning constraints** between two specified rooms allow, for example, expressing the fact that a room is located to the north of another room.

– **Minimum and maximum distance constraints** between two rooms allow expressing the proximity between two given rooms.

Topological constraints occur naturally in the preliminary design phase in architecture and can typically be expressed by using reified or global constraints.

• An **implicit constraint** puts a global condition that is inherent to floor planning problems between all the spaces of the floor. We typically have:

  – **Inclusion** of each room and circulation within the contour.

  – **Partitioning** of the placement space (i.e., no wasted space is permitted). This is usually a hard constraint which requires specific propagation in order to prevent the creation of wasted space.

  – **Non-overlapping** between rooms.

  – **Symmetry breaking constraints** between identical rooms imposes, for example, a lexicographic order between their respective lower leftmost corners.

Such constraints can typically be expressed by using global constraints, such as `DIFFN`, `GEOST`, or `LEXCHAIN_LESS`.

Finally, in order to allocate as much surface as possible to the rooms, one wants sometimes to minimise the total circulation area between the different rooms.

In order to illustrate these constraints we now consider an example of floor planning problem taken from R. Maculet PhD thesis [281] involving 11 spaces. Constraints on the dimensions of these space are:

• The **floor** where to place everything has a size of 12 by 10 meters.

• The **living** has a surface between 33 and 42 square meters and a minimum size of 4 by 4.

• The **kitchen** has a surface between 9 and 15 square meters and a minimum size of 3 by 3.

• The **shower** has a surface between 6 and 9 square meters and a minimum size of 2 by 2.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

Figure 3.28: A solution to Maculet floor planning problem that minimises the total area of the corridors

- The *toilet* has a surface between 1 and 2 square meters and a minimum size of 1 by 1.
- The *first and second parts of the corridor* have both a surface between 1 and 12 square meters and a minimum size of 1 by 1.
- The *first, second and third rooms* have all a surface between 11 and 15 square meters and a minimum size of 3 by 3.
- The *fourth room* has a surface between 15 and 20 square meters and a minimum size of 3 by 3.

Topological constraints between spaces are:
- The *living* is located on the south-west contour. The *kitchen*, the *first*, *second* and *third rooms* are either located on the south or on the north contour. The *fourth room* is on the south contour.
- All spaces, except the *kitchen*, are adjacent to one of the *corridors* with at least 1 meter of full contact.
- The *kitchen* is adjacent to the *living* and to the *shower*.
- The *toilet* is adjacent to the *kitchen* or to the *shower*.
- The *first* and the *second parts* of the *corridor* are adjacent and fully in contact.

Finally no wasted space is permitted. Figure 3.28 presents a solution to the corresponding floor planning problem that minimises the area of the two corridors.
3. DESCRIPTION OF THE CATALOGUE

3.7.105 ▶ Flow ➔

- ALL_BALANCE,
- ALLDIFFERENT,
- AMONG_SEQ,
- GLOBAL_CARDINALITY,
- GLOBAL_CARDINALITY_LOW_UP,
- GLOBAL_CARDINALITY_LOW_UP_NO_LOOP,
- GLOBAL_CARDINALITY_NO_LOOP,
- OPEN_ALLDIFFERENT,
- OPEN_GLOBAL_CARDINALITY,
- OPEN_GLOBAL_CARDINALITY_LOW_UP,
- OPEN_GLOBAL_CARDINALITY_LOW_UP_NO_LOOP,
- SAME,
- SAME_AND_GLOBAL_CARDINALITY,
- SAME_AND_GLOBAL_CARDINALITY_LOW_UP,
- SLIDING_SUM,
- SYMMETRIC_CARDINALITY,
- SYMMETRIC_GCC,
- USED_BY.

A constraint for which there is a filtering algorithm based on an algorithm that finds a feasible flow in a graph. The graph is usually constructed from the variables of the constraint as well as from their potential values. The usual game is to come up with a flow model such that there exists a one to one correspondence between feasible flows in the flow model and solutions to the constraint, so that detecting arcs that cannot carry any flow in any feasible flow will lead removing some values from the domains of some variables. The next sections provide standard flow models for the ALLDIFFERENT, the OPEN_ALLDIFFERENT, the GLOBAL_CARDINALITY_LOW_UP, the GLOBAL_CARDINALITY_LOW_UP_NO_LOOP, the USED_BY, the SAME, and the SAME_AND_GLOBAL_CARDINALITY_LOW_UP constraints.

A. Flow models for the ALLDIFFERENT and the OPEN_ALLDIFFERENT constraints

Figure 3.29 presents flow models for the ALLDIFFERENT and the OPEN_ALLDIFFERENT constraints. Blue arcs represent feasible flows respectively corresponding to the solutions ALLDIFFERENT(\langle x_1 = 1, x_2 = 2, x_3 = 3, x_4 = 4, x_5 = 5 \rangle) and OPEN_ALLDIFFERENT(\{1, 2, 3, 5\}, \langle x_1 = 1, x_2 = 2, x_3 = 3, x_4 = 3, x_5 = 4 \rangle), while red arcs correspond to arcs that cannot carry any flow if the constraint has a solution. Tables 3.11 and 3.12 respectively provide the initial domains of the variables we assume for the ALLDIFFERENT and OPEN_ALLDIFFERENT constraints.

- Within the context of the ALLDIFFERENT constraint the assignments \(x_3 = 1, x_3 = 2\) and \(x_4 = 2\) are forbidden since values 1 and 2 must already be assigned to variables \(x_1\) and \(x_2\). Finally the assignments \(x_4 = 3\) and \(x_5 = 3\) are also forbidden since values 1, 2 and 3 must be assigned to variables \(x_1, x_2\) and \(x_3\).

- Within the context of the OPEN_ALLDIFFERENT constraint, the assignment \(x_4 = 3\) does not matter at all since the position of \(x_4\) within \(\langle x_1 = 1, x_2 = 2, x_3 = 3, x_4 = 3, x_5 = 4 \rangle\) (i.e., position 4) does not belong to the set of variables.

12 Sometimes it is also constructed from the reformulation of a global constraint in term of a conjunction of linear constraints. This is the case, for example, for the AMONG_SEQ and the SLIDING_SUM global constraints.
Table 3.11: Domains of the variables for the \texttt{ALLDIFFERENT} constraint of Figure 3.29.

positions $\{1, 2, 3, 5\}$. We can only prune according to those variables that for sure should be assigned distinct values. Consequently $x_3 = 1$ and $x_3 = 2$ are forbidden since values 1 and 2 must already be assigned to $x_1$ and $x_2$. Finally the assignment $x_5 = 3$ is also forbidden since values 1, 2 and 3 must be assigned to $x_1, x_2$ and $x_3$.

B. Flow models for the \texttt{GLOBAL\_CARDINALITY\_LOW\_UP} and the \texttt{GLOBAL\_CARDINALITY\_LOW\_UP\_NO\_LOOP} constraints

Figure 3.30 presents flow models for the \texttt{GLOBAL\_CARDINALITY\_LOW\_UP} and the \texttt{GLOBAL\_CARDINALITY\_LOW\_UP\_NO\_LOOP} constraints. Blue arcs represent feasible

3. DESCRIPTION OF THE CATALOGUE

within the context of the \textsc{global\_cardinality\_low\_up} constraint variables \( x_1, x_2, x_3 \) and \( x_4 \) take their values within the set \{1, 2\}. Since each value in \{1, 2\} can be used at most 2 times, variables different from \( x_1, x_2, x_3, x_4 \) cannot be assigned a value in \{1, 2\}. Consequently, \( x_5 \neq 1, x_5 \neq 2 \) and \( x_6 \neq 2 \). Since value 3 is the only remaining value for variable \( x_5 \), and since value 3 can be
assigned to at most one variable, the assignments $x_6 \neq 3$ and $x_7 \neq 3$ are also forbidden.

- On the one hand we should have exactly two assignments of the form $x_i = i$ ($i \in [1, 7]$), since the first and second arguments of the constraint

$$x_1, x_2, x_3, x_4 \in [1, 2],$$
$$x_5 \in [1, 2, 3], x_6 \in [2, 3, 4, 5],$$
$$x_7 \in [3, 5],$$
$$GCC = \begin{pmatrix}
1, 1, 2, 2, 1, 2, 3, 1, 1, 1, 2, 2, 3, 3, 1, 1, 4, 1, 2, 5, 0, 2,
x_i, x_5, x_6, x_7
\end{pmatrix}.$$

$$x_1, x_2, x_3, x_5 \in [1, 2],$$
$$x_4 \in [1, 2, 3], x_6 \in [2, 4, 5], x_7 \in [3, 4, 5],$$
$$MINLOOP = 2, MAXLOOP = 2,$$
$$GCC_NOLOOP = \begin{pmatrix}
MINLOOP, MAXLOOP, x_1, x_2, x_3, x_4, x_5, x_6, x_7
\end{pmatrix}.$$

Figure 3.30: Flow models for the `GLOBAL_CARDINALITY_LOW_UP` and the `GLOBAL_CARDINALITY_LOW_UP_NO_LOOP` constraints described in Tables 3.13 and 3.14: in both cases a first layer consists of the variables of the constraint and a second layer corresponds to the values that can be assigned to the variables (in the second model, the loop node represents an anonymous value $i$ corresponding to assignments of the form $x_i = i$); each arc has a lower and upper capacity regarding the flow it can carry; arcs entering a node associated with a variable must carry a flow of 1 since each variable must be assigned a single value, while arcs exiting a node associated with a value have a capacity set accordingly the last argument of the constraint (i.e., the collection of values VALUES).
3. DESCRIPTION OF THE CATALOGUE

Table 3.14: Domains of the variables and minimum and maximum number of occurrences of each value for the GLOBAL/Cardinality_LOW_UP_NO_LOOP constraint of Figure 3.30; to the entry named loop corresponds the interval $[\text{MINLOOP}, \text{MAXLOOP}]$ where $\text{MINLOOP}$ and $\text{MAXLOOP}$ respectively correspond to the first and second arguments of the GLOBAL/Cardinality_LOW_UP_NO_LOOP constraint.

</tbody>
</table>

GLOBAL/Cardinality_LOW_UP_NO_LOOP are both set to two. Since the two variables $x_1$ and $x_2$ are the only variables such that $i \in \text{dom}(x_i)$ we must have $x_1 = 1$ and $x_2 = 2$, i.e. $x_1 \neq 2$ and $x_2 \neq 1$.

On the other hand, since we should have at least $1 + 2 + 1 + 1 = 5$ assignments of the form $x_i = j$ ($i \neq j, j \in [1,4]$) and since only 5 variables $x_i$ (with $i \in [3,7]$) can be assigned a value $j$ in $[1,4]$ with $i \neq j$, these variables should not be assigned a value outside interval $[1,4]$, i.e. $x_6 \neq 5$ and $x_7 \neq 5$.

C. Flow models for the USED_BY and the SAME constraints

Figure 3.31 presents flow models for the USED_BY and the SAME constraints. Blue arcs represent feasible flows respectively corresponding to the solutions USED_BY($\langle x_1 = 2, x_2 = 4, x_3 = 6 \rangle, \langle y_1 = 2, y_2 = 4 \rangle$) and SAME($\langle x_1 = 2, x_2 = 4, x_3 = 5 \rangle, \langle y_1 = 2, y_2 = 4, y_3 = 5 \rangle$), while red arcs correspond to arcs that cannot carry any flow if the constraint has a solution. Within the context of the SAME constraint, the assignment $x_1 = 1$ is forbidden since $1 \notin \text{dom}(y_1) \cup \text{dom}(y_2) \cup \text{dom}(y_3)$. Consequently $x_1 = 2$ and, since $y_1$ is the only variable of $\{y_1, y_2, y_3\}$ that can be assigned value 2, the assignment $y_1 = 3$ is forbidden. Now since $3 \notin \text{dom}(y_1) \cup \text{dom}(y_2) \cup \text{dom}(y_3)$ the assignment $x_2 = 3$ is also forbidden. Finally $x_3 = 6$ is forbidden since $6 \notin \text{dom}(y_1) \cup \text{dom}(y_2) \cup \text{dom}(y_3)$.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

\[ x_1 \in [1, 2], x_2 \in [3, 4], x_3 \in [4, 6], \]
\[ y_1 \in [2, 3], y_2 \in [4, 5], \]
\[ \text{USED\_BY}(x_1, x_2, x_3, (y_1, y_2)) \]
\[ x_1 \in [1, 2], x_2 \in [3, 4], x_3 \in [4, 6], \]
\[ y_1 \in [2, 3], y_2 \in [4, 5], y_3 \in [4, 5], \]
\[ \text{SAME}(x_1, x_2, x_3, (y_1, y_2, y_3)) \]

Figure 3.31: Flow models for the \text{USED\_BY} and the \text{SAME} constraints described in Tables 3.15 and 3.16: in both cases a first layer consists of the variables \( x_i \) of the first argument of both constraints, a second layer corresponds to the values that can be assigned to the variables \( x_i \) and \( y_i \) (i.e., the first and second arguments), and a third layer consists of the variables \( y_i \) of the second argument of both constraints; there is an arc from a variable \( x_i \) (resp. \( y_i \)) to a value \( v \) if, and only if, value \( v \) can be assigned to variable \( x_i \) (resp. \( y_i \)); each arc has a lower and upper capacity regarding the flow it can carry; since for both constraints each value assigned to a variable of the second argument must also correspond to a value assigned to a variable of the first argument the arcs exiting the \( y_i \) must carry a flow of 1.

D. **Flow model for the SAME_AND_GLOBAL_CARDINALITY_LOW_UP constraint**

Figure 3.32 presents a flow model for the SAME_AND_GLOBAL_CARDINALITY_LOW_UP constraint. Blue arcs represent the feasible flow corresponding to the solution SAME_AND_GLOBAL_CARDINALITY_LOW_UP ($x_1 = 2, x_2 = 4, x_3 = 4, y_1 = 2, y_2 = 4, y_3 = 4, (\text{val} - 1 \text{omin} - 0 \text{omax} - 1, \text{val} - 2 \text{omin} - 1 \text{omax} - 2, \text{val} - 3 \text{omin} - 0 \text{omax} - 3, \text{val} - 4 \text{omin} - 2 \text{omax} - 3, \text{val} - 5 \text{omin} - 0 \text{omax} - 2, \text{val} - 6 \text{omin} - 0 \text{omax} - 1)$), while red arcs correspond to arcs that cannot carry any flow if the constraint has a solution. The assignment $x_1 = 1$ is forbidden since $1 \notin dom(y_1) \cup dom(y_2) \cup dom(y_3)$. Consequently $x_1 = 2$ and, since $y_1$ is the only variable of $\{y_1, y_2, y_3\}$ that can be assigned value 2, the assignment $y_1 = 3$ is forbidden. Now since $3 \notin dom(y_1) \cup dom(y_2) \cup dom(y_3)$ the assignment $x_2 = 3$ is also forbidden. The assignment $x_3 = 6$ is forbidden since $6 \notin dom(y_1) \cup dom(y_2) \cup dom(y_3)$. Finally $x_3 = 5, y_2 = 5$ and $y_3 = 5$ are also forbidden since value 4 must be assigned to at least two variables.
\begin{align*}
x_1 \in [1, 2], & \ x_2 \in [3, 4], \ x_3 \in [4, 6], \\
y_1 \in [2, 3], & \ y_2 \in [4, 5], \ y_3 \in [4, 5], \\
\text{SAME\_AND\_GCC} & \left( \langle x_1, x_2, x_3 \rangle, \langle y_1, y_2, y_3 \rangle, \langle 1, 0, 1, 2, 1, 2, 3, 0, 3, 4, 2, 3, 5, 0, 2, 6, 0, 1 \rangle \right)
\end{align*}

A constraint that allows for representing a functional dependency between possibly several domain variables and a single domain variable. A sequence of variables $X_1, X_2, \ldots, X_n$ is said to functionally determine another variable $Y$ if and only if each potential tuple of values of $X_1, X_2, \ldots, X_n$ is associated with exactly one potential value of $Y$ (i.e., $Y$ is a function of $X_1, X_2, \ldots, X_n$). For each constraint we indicate whether its functional dependency is defined in intention or in extension. We also indicate which variable var is determined by the functional dependency. Within
the Arg. properties slot of a constraint that mentions the functional dependency keyword, we also mention which variables determine \( \text{var} \).

Finally, the keyword Pure functional dependency provides the list of constraints that are only defined by one or several functional dependencies. For example, the \( \text{NVALUE}(n, \langle v_1, v_2, \ldots, v_m \rangle) \) constraint is only defined in term of a functional dependency (i.e., \( n \) is equal to the number of distinct values in \( v_1, v_2, \ldots, v_m \)), while the \( \text{TREE}(n, \langle \text{node}_1, \text{node}_2, \ldots, \text{node}_m \rangle) \) constraint is not only defined in term of a functional dependency since, in addition of counting trees, it also enforces no cycle in the corresponding graph.

A constraint between geometrical objects (e.g., points, line segments, rectangles, orthotopes) or a constraint selecting a subset of points so that a given geometrical property holds (e.g., distance).
3. DESCRIPTION OF THE CATALOGUE

3.7.109  Glue matrix

A reversible constraint for which the catalogue provides an automaton with counters and a glue matrix [38]. A glue matrix is indexed by the states of the automaton associated with the considered constraint as well as by the states of the automaton associated with the reverse of the considered constraint. In the following we assume that the signature constraint involves a consecutive variables of the sequence of variables of the reversible constraint (the signature constraint encodes the mapping of the sequence of variables of the constraint to symbols of the alphabet of the automaton). We consider a sequence of variables and a prefix and suffix of this sequence such that the prefix and suffix have \( a - 1 \) variables in common. Let \( \overrightarrow{q} \) (resp. \( \overleftarrow{q} \)) be the state of the automaton associated with the constraint (resp. the reverse constraint) upon reading the prefix (resp. the reverse of the suffix). The entry of the glue matrix corresponding to the state pair \((\overrightarrow{q}, \overleftarrow{q})\) provides a function for computing the result associated with the sequence from the counters values associated with the prefix and the reverse suffix.

As an example consider the \texttt{PEAK}(N, \texttt{VARIABLES}), which holds if \( N \) is equal to the number of peaks of the sequence of variables \texttt{VARIABLES}. A peak corresponds to an increase between consecutive variables followed by a decrease between consecutive variables. Figure 3.33 gives the corresponding automaton that returns the number of peak of a sequence where, to each pair of consecutive variables \((\texttt{VAR}_i, \texttt{VAR}_{i+1})\) corresponds a signature variable \( S_i \) passed to the automaton. The following signature
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

constraint links $\text{VAR}_i$, $\text{VAR}_{i+1}$ and $S_i$: $(\text{VAR}_i < \text{VAR}_{i+1} \iff S_i = 0) \land (\text{VAR}_i = \text{VAR}_{i+1} \iff S_i = 1) \land (\text{VAR}_i > \text{VAR}_{i+1} \iff S_i = 2)$.

Figure 3.33: Automaton of the $\text{PEAK}$ constraint and its glue matrix (an accepting state is denoted graphically by a double circle)

Figure 3.34 illustrates the use of the glue matrix of the $\text{PEAK}$ constraint on the sequence 1, 1, 4, 8, 6, 2, 7, 1 decomposed in a prefix 1, 1, 4, 8 and a suffix 8, 6, 2, 7, 1 that overlap by one position, one position since the arity of the signature constraint is equal to two. Since the automaton of the $\text{PEAK}$ constraint ends up in state $u$ when applied to the prefix and to the reverse suffix we use the lower rightmost entry of the glue matrix to link the total number of peaks of the sequence 1, 1, 4, 8, 6, 2, 7, 1 with the number of peaks of the prefix 1, 1, 4, 8 and the suffix 8, 6, 2, 7, 1.

Figure 3.34: Illustrating the use of the state pair $(u, u)$ of the glue matrix for linking $\Upsilon$ with the counters variables obtained after reading the prefix 1, 1, 4, 8 and corresponding suffix 8, 6, 2, 7, 1 of the sequence 1, 1, 4, 8, 6, 2, 7, 1; note that the suffix 8, 6, 2, 7, 1 (in pink) is proceed in reverse order; the left (resp. right) table shows the initialisation (for $i = 0$) and the evolution (for $i > 0$) of the state of the automaton and of its counter $C$ upon reading the prefix 1, 1, 4, 8 (resp. the suffix 1, 7, 2, 6, 8).
3.7.110  ♦Golomb ruler ▲

- ALLDIFFERENT,  
- GOLOMB,

A constraint that allows for expressing the Golomb ruler problem. A Golomb ruler is a set of integers (marks) \( a_1 < \cdots < a_k \) such that all the differences \( a_i - a_j \) \((i > j)\) are distinct.

3.7.111  ♦Graph colouring ▲

- ALLDIFFERENT,  
- INT_VALUE_PRECEDE_CHAIN,  
- K_ALLDIFFERENT.

A constraint that can be used for the graph colouring problem. The graph colouring problem is to colour with a restricted number of colours the vertices of a given undirected graph in such a way that adjacent vertices are coloured with distinct colours.

3.7.112  ♦Graph constraint ▲

- BALANCE_CYCLE,

• SYMMETRIC_ALLDIFFERENT,
• SYMMETRIC_ALLDIFFERENT_LOOP,
• TEMPORAL_PATH,
• TOUR,
• TREE,
• TREE_RANGE,
• TREE_RESOURCE.

A constraint that selects a subgraph from a given initial graph so that this subgraph satisfies a given property and/or belong to a specific graph class.

3.7.113 ▶Graph partitioning constraint ◀ [18 CONS]

• BALANCE_CYCLE,
• BALANCE_PATH,
• BALANCE_TREE,
• BINARY_TREE,
• CIRCUIT,
• CYCLE,
• CYCLE_CARD_ON_PATH,
• CYCLE_RESOURCE,
• GRAPH_CROSSING,
• MAP,
• PATH,
• PROPER_CIRCUIT,
• SYMMETRIC_ALLDIFFERENT,
• SYMMETRIC_ALLDIFFERENT_LOOP,
• TEMPORAL_PATH,
• TREE,
• TREE_RANGE,
• TREE_RESOURCE.

A constraint that partitions the vertices of a given initial graph and that keeps a single successor for each vertex so that each partition corresponds to a specific pattern.
3.7.114  ♦Guillotine cut  ♦

- DIFFN_COLUMN,
- TWO_ORTH_COLUMN.

A constraint that can enforce some kind of guillotine cut. In a lot of cutting problems the stock sheet as well as the pieces to be cut are all shaped as rectangles. In a guillotine cutting pattern all cuts must go from one edge of the rectangle corresponding to the stock sheet to the opposite edge.

3.7.115  ♦Hall interval  ♦

- ALLDIFFERENT,
- GLOBAL_CARDINALITY.

A constraint for which some filtering algorithms take advantage of Hall intervals. Given a set of domain variables, a Hall set is a set of values \( H = \{ v_1, v_2, \ldots, v_h \} \) such that there are \( h \) variables whose domains are contained in \( H \). A Hall interval is a Hall set that consists of an interval of values (and can therefore be specified by its endpoints).

3.7.116  ♦Hamiltonian  ♦

- CIRCUIT,
- TOUR.

A constraint enforcing to cover a graph with one Hamiltonian circuit or cycle. This corresponds to finding a circuit (respectively a cycle) passing all the vertices exactly once of a given digraph (respectively undirected graph).
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.117 Heuristics

- ALLDIFFERENT,
- DISCREPANCY,
- INVERSE,
- INVERSE_OFFSET,
- INVERSE_WITHIN_RANGE.

A constraint that was introduced for expressing a heuristic or a constraint (ALLDIFFERENT) for which an algorithm that evaluate the number of solutions was proposed.

Remark: when we do not have good bounds on the cost variable of a constrained optimisation problem, skewed binary search was introduced in [389] in order to take advantage of the fact that it is usually easier to improve the current solution cost’s than to prove that a problem is not feasible.

3.7.118 Heuristics and Berge-acyclic constraint network

Consider a conjunction $C$ of constraints such that:

1. The constraint network $N$ corresponding to the conjunction $C$ is not Berge-acyclic.
2. The filtering algorithms associated with the different constraints of the conjunction $C$ all achieve arc-consistency.

In this context, one can design a heuristic that fix enough variables, but not all, so that the remaining constraint network $N$ becomes Berge-acyclic. This can be achieved by fixing the variables in such a way that some constraints get entailed even though they still mention some variables that are not yet fixed. Let us illustrate that idea on a matrix model where we have a $R \times K$ matrix $M$ of domain variables taking a value in interval $[1, V]$. Assume that:

- On each row of $M$ we have a constraint that can be described in term of a counter-free automaton.
- On each column of $M$ we have a GLOBAL_CARDINALITY_LOW_UP constraint that only imposes a minimum number of occurrences for each value in $[1, V]$ (i.e., the maximum number of occurrences is not constrained at all).

The point is that, as soon as the constraint network becomes Berge-acyclic no search is needed any more to check that there is a solution, provided we achieve arc-consistency on the remaining constraints. This stems from [143], which itself is a consequence of [183].
Note that arc-consistency can be achieved for such constraints. For this constraint pattern, an assignment strategy that systematically tries creating a Berge-acyclic constraint network can be achieved as follows. Fix some variables so that $K - 1$ column constraints (i.e., $\text{GLOBAL}_{\text{CARDINALITY}}_{\text{LOW}_{\text{UP}}}$ constraints) get entailed. If this is the case the remaining constraint network consists of $R$ rows constraints and of a single column constraint.

As illustrated by Figure 3.35, this typically corresponds to a Berge-acyclic constraint network. Let us now finally explain how to assign values to a subset of variables of a $\text{GLOBAL}_{\text{CARDINALITY}}_{\text{LOW}_{\text{UP}}}$ constraint that only restricts the minimum number of occurrences of certain values so that it becomes entailed. As an example, let us consider a $\text{GLOBAL}_{\text{CARDINALITY}}_{\text{LOW}_{\text{UP}}}$ constraint involving 10 variables which forces at least three occurrences of value 1 and one occurrence of value 2. A heuristic needs only fixing 4 variables out of the 10 variables to values 1, 1, 1 and 2 so that the corresponding $\text{GLOBAL}_{\text{CARDINALITY}}_{\text{LOW}_{\text{UP}}}$ gets entailed. A typical instance of this pattern corresponds to nurse scheduling problems where:

- Each row of $\mathcal{M}$ corresponds to the timetable of a person over $K$ consecutive days. Using a counter free automaton the corresponding row constraint encodes all legal rules of a valid schedule.

- Each column of $\mathcal{M}$ describes the request for a minimum number of services on a given day. Types of work (i.e., values in $[1, V]$) can be, for example, interpreted...
as a morning shift, an afternoon shift, a night shift or a day off.

The heuristic first addresses the coverage constraints only (i.e., the
GLOBAL/Cardinality_LOW_UP constraints). It seeks to assign enough nurses
to given shifts on given day to satisfy all but one coverage constraints. Once this is
done, the remaining variables can be labelled without search.

3.7.119 ▶ Heuristics and lexicographical ordering ➔ [8 CONS]

- LEX_CHAIN_GREATER,
- LEX_CHAIN_GREATEREQ,
- LEX_CHAIN_LESS,
- LEX_CHAIN_LESSEQ,
- LEX_GREATER,
- LEX_GREATEREQ,
- LEX_LESS,
- LEX_LESSEQ.

Using a constraint that imposes a lexicographical ordering between vectors of vari-
ables may influence the heuristic used for fixing the variables. In particular it may be
a very bad idea to systematically fix the less significant components before the most
significant components.

3.7.120 ▶ Heuristics for two-dimensional rectangle placement problems ➔ [2 CONS]

- DIFFN,
- GEOST.

A constraint for which one of the following heuristics was used in the context of
two-dimensional rectangles placement problems where rectangles should not overlap.
For easy instances involving non-overlapping constraints where there is enough room,
a standard heuristic where one fixes each rectangle successively by trying out its possible values for its $x$-coordinate and its $y$-coordinate will do the job. However, for more difficult problems a less aggressive heuristic is usually required, especially when the filtering algorithms attached to the constraints are weak. The paradox is that less aggressive heuristics sometimes do not find rapidly a first solution to easy instances since they may potentially artificially create infeasible subproblems.

**Dual strategy for rectangle placement problems with no slack**

When the available space is equal to the total area of the rectangles to place (i.e., we have no slack) this is a two-phase search procedure originally introduced in [1] where we first fix all the $x$-coordinates and then, in the second phase, all the $y$-coordinates. The intuitions behind this heuristic are:

- To **systematically** fill the placement space from right to left in order to avoid creating small holes that cannot be filled.

- To decrease the combinatorial aspect of the problem by **focusing first on all $x$-coordinates**. This stems from the fact that it is usually easy to extend a partial solution, where all $x$-coordinates are fixed, to a full solution.

Fixing the $x$-coordinates is done by:

- First, compute the minimum $\min_x$ over the minimum values of the $x$-coordinates of the rectangles for which the $x$-coordinate is not already fixed.

- Second, create a choice point and, in each branch:
  
  - Fix the $x$-coordinate of a rectangle $R$ for which the $x$-coordinates is not already fixed to value $\min_x$. Usually rectangles are considered by decreasing height (and decreasing width in case of tie).
  
  - On backtracking, enforce that the $x$-coordinate of rectangle $R$ is strictly greater than $\min_x$.

- Third, fail when all branches issued from a choice point have been tried (since otherwise we would create a hole at position $\min_x$ because, on the $x$ axis all rectangles that could start at position $\min_x$ were delayed after $\min_x$; in order to not cut valid choices, this third part assumes that the minimum value of the $x$-coordinate of each rectangle is pruned with respect to the compulsory part profile of the corresponding CUMULATIVE constraint.).

Since, as we said early on, it is usually easy to extend a partial solution, where all $x$-coordinates are fixed, to a full solution where all $y$-coordinates are also fixed, the search strategy used for fixing the $y$-coordinates is usually not so important, at least when strong filtering algorithms are used [41].
Strategy that gradually creates a compulsory part

This is a four-phase search procedure that can be used even when the slack is not equal to zero. We first gradually restrict all the \(x\)-coordinates and then, in the second phase, all \(y\)-coordinates without fixing them immediately. Then in the third phase we fix all the \(x\)-coordinates by trying each value (or by making a binary search). Finally in the last phase we fix all the \(y\)-coordinates as in the third phase. The intuitions behind this heuristic are:

- To restrict the \(x\)-coordinate of each rectangle \(R\) in order to just create some compulsory part for \(R\) on the \(x\) axis. The hope is that it will trigger the filtering algorithm associated with the \texttt{CUMULATIVE} constraint involved by the non-overlapping constraint, even though the starts of the rectangles on the \(x\) axis are not yet completely fixed.

- Again, as in the previous heuristic, to decrease the combinatorial aspect of the problem by first focussing on all \(x\)-coordinates.

Restricting gradually the \(x\)-coordinates in phase one is done by partitioning the domain of the \(x\)-coordinate of each rectangle \(R\) into intervals whose sizes induce a compulsory part on the \(x\) axis for rectangle \(R\). To achieve this, the size of an interval has to be less than or equal to the size of rectangle \(R\) on the \(x\) axis. Picking the best fraction of the size of a rectangle on the \(x\) axis depends on the problem as well as on the filtering algorithms behind the scene. Within the context of the smallest rectangle area problem [401] and of the SICStus implementation of \texttt{DISJOINT} and \texttt{CUMULATIVE} H. Simonis and B. O’Sullivan have shown empirically that the best fraction was located within interval \([0.2, 0.3]\). Restricting the \(y\)-coordinates in phase two can be done in a way similar to restricting the \(x\)-coordinates in phase one.

3.7.121 **Hungarian method for the assignment problem**

A constraint that can use the Hungarian method for the assignment problem [254] in order to evaluate the minimum or maximum value of one of its argument. Given \(n\) persons, \(n\) tasks and a corresponding \(n\) by \(n\) cost matrix, the assignment problem is the search for an assignment of persons to tasks so that the sum of the costs is maximised.
3. DESCRIPTION OF THE CATALOGUE

3.7.122 Hybrid-consistency

Denotes that, for a given constraint involving both domain and set variables, there is a filtering algorithm that ensures hybrid-consistency. A constraint $\text{ctr}$ defined on the distinct domain variables $V^d_1, \ldots, V^d_n$ and the distinct set variables $V^s_{n+1}, \ldots, V^s_m$ is hybrid-consistent if and only if:

- For every pair $(V^d, v)$ such that $V^d$ is a domain variable of $\text{ctr}$ and $v \in \text{dom}(V^d)$, there exists at least one solution to $\text{ctr}$ in which $V^d$ is assigned the value $v$.

- For every pair $(V^s, v)$ such that $V^s$ is a set variable of $\text{ctr}$, if $v \in V^s$ then $v$ belongs to the set assigned to $V^s$ in all solutions to $\text{ctr}$ and if $v \in V^s \setminus V^s$ then $v$ belongs to the set assigned to $V^s$ in at least one solution and is excluded from this set in at least one solution.

3.7.123 Hypergraph

Denotes that a constraint uses in its definition at least one arc constraint involving more than two vertices.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.124 ▼Included ➔ [2 CONS]

- IN,
- IN_SET.

Enforces that a domain or a set variable take a value within a list of values (possibly a single value).

3.7.125 ▼Inclusion ➔ [8 CONS]

- K_USED_BY,
- K_USED_BY_INTERVAL,
- K_USED_BY_MODULO,
- USED_BY,
- USED_BY_INTERVAL,
- USED_BY_MODULO,
- USED_BY_PARTITION,
- USES.

Denotes that a constraint can model the inclusion of one multiset within another multiset. Usually we consider multiset of values (e.g., USED_BY) but this can also be multisets of equivalence classes (see, e.g., the USED_BY_INTERVAL, USED_BY_MODULO, and USED_BY_PARTITION constraints).

3.7.126 ▼Incompatible pairs of values ➔ [1 CONS]

- ALLENTDIFFERENT_PARTITION.

A constraint that is related to the fact that some pairs of values are incompatible (i.e., the two values of each pair of values cannot simultaneously be part of a solution).
3. DESCRIPTION OF THE CATALOGUE

3.7.127 ▼Indistinguishable values ➔ [3 CONS]

- INT_VALUE_PRECEDE,
- INT_VALUE_PRECEDE_CHAIN,
- SET_VALUE_PRECEDE.

A constraint that can be used for breaking symmetries of indistinguishable values [268]. Indistinguishable values in a solution to a problem can be swapped to construct another solution to the same problem.

3.7.128 ▼Interval ➔ [16 CONS]

- ALLDIFFERENT_INTERVAL,
- AMONG_INTERVAL,
- BALANCE_INTERVAL,
- COMMON_INTERVAL,
- DOMAIN,
- IN_INTERVAL,
- IN_INTERVALS,
- INTERVAL_AND_COUNT,
- INTERVAL_AND_NUM,
- KSAME_INTERVAL,
- K_USED_BY_INTERVAL,
- N_INTERVAL,
- SAME_INTERVAL,
- SOFTSAME_INTERVAL_VAR,
- SOFT_USED_BY_INTERVAL_VAR,
- USED_BY_INTERVAL.

Denotes that a constraint puts a restriction related to a set of fixed intervals (or on one fixed interval).
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.129 Involution

- SYMMETRIC_ALLDIFFERENT_LOOP
- SYMMETRIC_ALLDIFFERENT

Denotes that a constraint can directly model permutations of order 2.

3.7.130 Joker value

- ALL_EQUAL_EXCEPT_0
- ALLDIFFERENT_EXCEPT_0
- AMONG_DIFF_0
- CONNECT_POINTS
- CYCLIC_CHANGE_JOKER
- FIRST_VALUE_DIFF_0
- ITH_POS_DIFFERENT_FROM_0
- LEX_ALLDIFFERENT_EXCEPT_0
- MINIMUM_EXCEPT_0
- MIN_SIZE_FULL_ZERO_STRETCH
- NVALUES_EXCEPT_0
- PERIOD_EXCEPT_0
- SYMMETRIC_ALLDIFFERENT_EXCEPT_0
- WEIGHTED_PARTIAL_ALLDIFF

Denotes that, for some variables of a given constraint, there exists specific values that have a special meaning: for instance they can be assigned without breaking the constraint. As an example consider the ALLDIFFERENT_EXCEPT_0 constraint, which forces a set of variables to take distinct values, except those variables that are assigned to 0.
3. DESCRIPTION OF THE CATALOGUE

3.7.131  Klee’s measure problem  [1 CONS]

- DIFFN.

Denotes that, checking the feasibility of a ground instance of a constraint, is related to the Klee’s measure problem: given a collection of axis-aligned multi-dimensional boxes, how quickly can one compute the volume of their unions.

3.7.132  Labelling by increasing cost  [2 CONS]

- ELEM,
- ELEMENT.

Some optimisation problems involve minimising a cost \( c \) consisting of a sum of elementary costs \( c_1, c_2, \ldots, c_n \), where each elementary cost \( c_i \) (1 \( \leq \) \( i \) \( \leq \) \( n \)) is directly linked to the value assigned to a decision variable \( v_i \). Without loss of generality we assume that each decision variable will be assigned a value between 1 and \( m \). The link between a decision variable \( v_i \) and its corresponding cost \( c_i \) is usually expressed by a constraint of the form \( \text{ELEMENT}(v_i, \langle c_{i,1}, c_{i,2}, \ldots, c_{i,m} \rangle, c_i) \) stating that \( c_i = j \Rightarrow c_i = c_{i,j} \). During search, while enumerating on the different values of a decision variable \( v_i \), we would like to try out values of \( v_i \) so that the corresponding cost \( c_i \) increases. This means we want to use a permutation \( \sigma_1, \sigma_2, \ldots, \sigma_m \) of 1, 2, \ldots, \( m \) such that \( c_{i,\sigma_1} \leq c_{i,\sigma_2} \leq \cdots \leq c_{i,\sigma_m} \). Note that such permutation can be obtained by sorting the costs \( c_{i,1}, c_{i,2}, \ldots, c_{i,m} \) by increasing order and by collecting the position \( \sigma_j \) where item \( c_{i,j} \) is located in the sorted list. Assuming that we perform arc-consistency on the \text{ELEMENT}, we now describe three different ways to obtain the effect we want to achieve:

- A first direct way is to use a built in facility that, given variable \( v_i \) and the corresponding list of values \( \sigma_1, \sigma_2, \ldots, \sigma_m \) introduced before, creates a choice point and tries to successively assign values \( \sigma_1, \sigma_2, \ldots, \sigma_m \) to \( v_i \). Note that, once \( v_i \) is fixed there is no need to enumerate on the corresponding elementary cost variable \( c_i \) since, by propagation, \( \text{ELEMENT}(v_i, \langle c_{i,1}, c_{i,2}, \ldots, c_{i,m} \rangle, c_i) \) will fix \( c_i \). Consequently the cost variables do not need to be passed to the search procedure.

- A second indirect way, used when we want to only rely on a standard built in that creates a choice point and tries to assign values to a variable in increasing value order, is to introduce an extra variable \( u_i \). The idea is to link variable \( u_i \) to variable \( v_i \) in such a way that, when we try to assign values in increasing value
order to variable \( u_i \), both variables \( v_i \) and \( c_i \) get fixed and, in addition, values of \( c_i \) are increasing. This can be modelled by introducing the following two \texttt{ELEMENT} constraints:

1. \texttt{ELEMENT}(\( u_i, \langle \sigma_1, \sigma_2, \ldots, \sigma_m \rangle, v_i \))
2. \texttt{ELEMENT}(\( v_i, \langle c_{i,1}, c_{i,2}, \ldots, c_{i,m} \rangle, c_i \))

The effect of a dedicated built in that tries to assign values to a variable according to an explicit list of values is achieved by introducing the first \texttt{ELEMENT} constraint. Again, once \( u_i \) is fixed the first \texttt{ELEMENT} constraint will fix variable \( v_i \). Then the second \texttt{ELEMENT} constraint will also fix variable \( c_i \). Consequently, both the cost and the decision variables do not need to be passed to the search procedure, i.e., we just need to pass the newly introduced variables \( u_i \).

- Finally, we can first label on the cost variable \( c_i \) in increasing value order. If the costs \( c_{i,1}, c_{i,2}, \ldots, c_{i,m} \) are all distinct then the \texttt{ELEMENT}(\( v_i, \langle c_{i,1}, c_{i,2}, \ldots, c_{i,m}, c_i \rangle \)) constraint will fix \( v_i \) by propagation since we assume \texttt{ELEMENT} to perform arc-consistency. Otherwise, when the costs \( c_{i,1}, c_{i,2}, \ldots, c_{i,m} \) are not all distinct, we also need to label the decision variable \( v_i \).

Figure 3.36: Given a decision variable \( v \) and a corresponding cost variable \( c \) linked by the \texttt{ELEMENT}(\( v, \langle 5, 6, 2, 9, 9 \rangle, c \)) constraint, illustration of three ways for labelling by increasing cost: part (A) labels directly on the decision variable \( v \) using an appropriate order so that successive values of \( c \) are increasing; part (B) introduces a variable \( u \) linked to \( v \) by the \texttt{ELEMENT}(\( u, \langle 3, 1, 2, 4, 5 \rangle, v \)) constraint and labels on \( u \) by increasing value order; part (C) labels first on the cost variable \( c \) by increasing value order, and then on variable \( v \).

Figure 3.36 illustrates the three ways of labelling previously introduced. The primitive \texttt{member}(\( var, list\_values \)) creates a choice point and tries to successively assign variable \( var \) an integer value from the list \( list\_values \) with respect to their ordering. The primitive \texttt{indomain}(\( var \)) also creates a choice point and tries to successively assign variable \( var \) an integer value of its domain, by increasing value order.
3. DESCRIPTION OF THE CATALOGUE

3.7.133 \(\bowtie\) Latin square \(\rightarrow\)

- \texttt{K\_ALLDIFFERENT}

\[
\begin{array}{ccc}
1&2&3 \\
3&1&4 \\
4&3&2 \\
\end{array}
\]

(A)

\[
\begin{array}{ccc}
1&2&3 \\
2&1&4 \\
3&4&1 \\
4&3&2 \\
\end{array}
\]

(B)

Figure 3.37: A partially filled Latin square and a possible completion

A constraint that can be used for modelling the Latin square completion problem.

A Latin square of order \(n\) is an \(n \times n\) array in which \(n\) distinct numbers in \([1, n]\) are arranged so that each number occurs once in each row and column. The Latin square completion problem is to complete a partially filled Latin square. Part (A) of Figure 3.37 gives a partially filled Latin square, while part (B) provides a possible completion. The Latin square completion problem is a pattern that occurs in some applications such as dynamic wavelength routing or sport timetabling.

3.7.134 \(\bowtie\) Lexicographic order \(\rightarrow\)

- \texttt{ALLPERM}, \texttt{COND\_LEX\_COST}, \texttt{COND\_LEX\_GREATER}, \texttt{COND\_LEX\_GREATEREQ}, \texttt{COND\_LEX\_LESS}, \texttt{COND\_LEX\_LESSEQ}, \texttt{LEX2}, \texttt{LEX\_BETWEEN}, \texttt{LEX\_CHAIN\_GREATER}, \texttt{LEX\_CHAIN\_GREATEREQ}, \texttt{LEX\_CHAIN\_LESS}, \texttt{LEX\_CHAIN\_LESSEQ}

- \texttt{LEX\_CHAIN\_GREATER}, \texttt{LEX\_CHAIN\_LESS}, \texttt{LEX\_CHAIN\_LESSEQ}, \texttt{LEX\_GREATER}, \texttt{LEX\_GREATEREQ}, \texttt{LEX\_LESS}, \texttt{LEX\_LESSEQ}, \texttt{LEX\_LESSEQ\_ALLPERM}, \texttt{STRICT\_LEX2}.

A constraint involving a lexicographic ordering relation in its definition.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.135 ▶Limited discrepancy search ◀

- DISCREPANCY.

A constraint for simulating limited discrepancy search [204]. Limited discrepancy search is useful for problems for which there is a successor ordering heuristic that usually leads directly to a solution. It consists of systematically searching all paths that differ from the heuristic path in at most a very small number of discrepancies. Figure 3.38 illustrates the successive search steps (B), (C), (D), (E) and (F) on the search tree depicted by part (A). We successively explore the subtree of (A) corresponding to a discrepancy of 0, 1, 2, 3 and 4. The number on each leave indicates the total number of discrepancies to reach a leave.

3.7.136 ▶Linear programming ◀

- ALLDIFFERENT,
- AMONG_SEQ,
- CIRCUIT,
- CUMULATIVE,
- DISJUNCTIVE,
- DOMAIN_CONSTRAINT,
- ELEMENT_GREATEREQ,
- ELEMENT_LESSEQ,
- GLOBAL_CARDINALITY_LOW_UP,
- K_ALLDIFFERENT,
- K_CUT,
- LINK_SET_TO_BOOLEANS,
- PATH_FROM_TO,
- REGULAR,
- SLIDING_SUM,
- STRONGLY_CONNECTED,
- SUM,
- TOUR.

A constraint for which a reference provides a linear relaxation (see, e.g., the ALLDIFFERENT, the CIRCUIT, the CUMULATIVE, the SUM, and the REGULAR [134] constraints) or a constraint for which the flow model was derived by reformulating the constraint as a linear program (see, e.g., the AMONG_SEQ and the SLIDING_SUM constraints), or a constraint that was also proposed within the context of linear programming (see, e.g., the CIRCUIT, and DOMAIN_CONSTRAINT constraints). In the context of linear programming the book of John N. Hooker [226] provides a significant set of relaxations for a number of global constraints.
3. DESCRIPTION OF THE CATALOGUE

Figure 3.38: Illustration of limited discrepancy search
### 3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

#### 3.7.137 Line segments intersection

- CROSSING,
- GRAPH,CROSSING,
- TWO_LAYER_EDGE,CROSSING.

A constraint on the number of line segment intersections.

#### 3.7.138 Logic

- CONTAINS_SBOXES,
- COVEREDBY_SBOXES,
- COVERS_SBOXES,
- DISJOINT_SBOXES,
- EQUAL_SBOXES,
- GEOST,
- GEOST_TIME,
- INSIDE_SBOXES,
- MEET_SBOXES,
- NON_OVERLAP_SBOXES,
- ORTH_ON_TOP_OF_ORTH,
- OVERLAP_SBOXES,
- PLACE_IN_PYRAMID,
- TWO_ORTH_ARE_IN_CONTACT,
- TWO_ORTH_COLUMN,
- TWO_ORTH_DO_NOT_OVERLAP,
- TWO_ORTH_INCLUDE.

A constraint which can be defined with first order logic formula encoded in the dedicated language introduced in [107].
A constraint which can be used for modelling the logigraphe problem. The logigraphe problem, see Figure 3.39 for an instance taken from [328, page 36], consists of colouring a board of squares in black or white, so that each row and each column contains a specific number of sequences of black squares of given size. A sequence of integers $s_1, s_2, \ldots, s_m \ (p \geq 1)$ enforces:

- a first block of $s_1$ consecutive black squares,
- a second block of $s_2$ consecutive black squares,
- $\ldots$,
- a last block of $s_p$ consecutive black squares.

Each block of consecutive black squares must be separated by at least one white square. Finally, white squares may possibly precede (respectively follow) the first (respectively the last) block of black squares. The logigraphe problem is NP-complete [422].

![Figure 3.39](image_url)

**Figure 3.39:** Part (A): an instance of a logigraphe and the initial deductions achieved after posting the constraints, Part (B): the corresponding unique solution.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

**CONSECUTIVE_GROUPS_OF_ONES** constraint is represented as a counter free automaton. A white or black square indicates an initial deduction (i.e., setting a variable to 0 or to 1). Part (B) of Figure 3.39 provides the unique solution found after developing three choices, assuming that variables are assigned from the uppermost to the lowermost row. Within a given row, variables are assigned from the leftmost to the rightmost column. Value 0 is tried first before value 1. Seven additional choices are required for proving that this solution is unique. Figure 3.40 displays the corresponding search tree. Within this figure, a variable \( V_{i,j} \) \((1 \leq i, j \leq 10)\) denotes the 0-1 variable associated with the \( i^{th} \) row and the \( j^{th} \) column of the board.

![Search tree](image-url)

Figure 3.40: Search tree developed for the logigraphe instance of Figure 3.39 (variables that are fixed by propagation were removed from the search tree)

---

\(^{14}\)Each time we try to assign a value to a not yet fixed variable, the number of choices is incremented by 1 just before making the assignment.
3. DESCRIPTION OF THE CATALOGUE

3.7.140 ▶Magic hexagon ◀

- ALLDIFFERENT,
- GLOBAL_CARDINALITY_WITH_COSTS.

A constraint that can be used for modelling some parts of the magic hexagon problem. The magic hexagon problem, see Figure 3.41 for an example, consists of finding an arrangement of \( n \) hexagons, where an integer from 1 to \( n \) is assigned to each hexagon so that (1) each integer from 1 to \( n \) occurs exactly once, (2) the sum of the numbers along any straight line is the same.

![Magic Hexagon](image)

Figure 3.41: A magic hexagon of order 3 filled by integers 1 through 19 where the sum of the integers in each row of cells, in all three directions, is 38

3.7.141 ▶Magic series ◀

- GLOBAL_CARDINALITY.

A constraint that allows for modelling the magic series problem with a single constraint. A non-empty finite sequence \( S = (s_0, s_1, \ldots, s_n) \) is magic if and only if there are \( s_i \) occurrences of \( i \) in \( S \) for each integer \( i \) ranging from 0 to \( n \). 3, 2, 1, 1, 0, 0, 0 is an example of such a magic series for \( n = 6 \).
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.142 ▶ Magic square ◀

- ALLDIFFERENT,
- GLOBAL_CARDINALITY_WITH_COSTS.

A constraint that can be used for modelling some parts of the magic square problem. The magic square problem consists in filling an $n$ by $n$ square with $n^2$ distinct integers so that the sum of each row and column and of both main diagonals be the same.

3.7.143 ▶ Matching ◀

- SYMMETRIC_ALLDIFFERENT,
- SYMMETRIC_ALLDIFFERENT_EXCEPT_0,
- SYMMETRIC_ALLDIFFERENT_LOOP,
- TOUR.

A constraint that allows for expressing that we want to find a perfect matching on a graph with an even number of vertices. A perfect matching on a graph $G$ with $n$ vertices is a set of $n/2$ edges of $G$ such that no two edges have a vertex in common.

A used generalisation so called degree-matching of a graph is a spanning subgraph where every vertex is associated with the bound degree of the matched edges.

3.7.144 ▶ Matrix ◀

- ALLPERM,
- COLORED_MATRIX,
- ELEMENT_MATRIX,
- LEX2,
- STRICT_LEX2.

A constraint on a matrix of domain variables (see, e.g., the ALLPERM, COLORED_MATRIX, LEX2, and STRICT_LEX2 constraints) or a constraint that allows
for representing the access to an element of a matrix (see, e.g., the \texttt{ELEMENT\_MATRIX} constraint).

\subsection{Matrix model} \[3.7.145\] \(\Rightarrow\) \([4 \text{ CONS}]\)

- \texttt{ALLPERM},
- \texttt{COLORED\_MATRIX},
- \texttt{LEX2},
- \texttt{STRICT\_LEX2}.

A constraint on a matrix of domain variables. A \textit{matrix model} is a model involving one matrix of domain variables.

\subsection{Matrix symmetry} \[3.7.146\] \(\Rightarrow\) \([13 \text{ CONS}]\)

- \texttt{ALLPERM},
- \texttt{INCREASING\_GLOBAL\_CARDINALITY},
- \texttt{LEX2},
- \texttt{LEX\_CHAIN\_GREATER},
- \texttt{LEX\_CHAIN\_GREATEREQ},
- \texttt{LEX\_CHAIN\_LESS},
- \texttt{LEX\_CHAIN\_LESSEQ},
- \texttt{LEX\_GREATER},
- \texttt{LEX\_GREATEREQ},
- \texttt{LEX\_LESS},
- \texttt{LEX\_LESSEQ},
- \texttt{LEX\_LESSEQ\_ALLPERM},
- \texttt{STRICT\_LEX2}.

A constraint that can be used for breaking certain types of symmetries within a matrix of domain variables.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.147 Maximum

- MAX_INDEX,
- MAX_N,
- MAX_VALUE,
- MAX_SIZE_SET_OF_CONSECUTIVE_VAR,
- MAXIMUM,
- MAXIMUM_MODULO.

A constraint for which the definition involves the notion of maximum.

3.7.148 Maximum clique

- ALL_MIN_DIST,
- ALLDIFFERENT,
- CLIQUE,
- DISJUNCTIVE.

A constraint (i.e., CLIQUE) that can be used for searching for a maximum clique in a graph, or a constraint (i.e., ALL_MIN_DIST, ALLDIFFERENT, DISJUNCTIVE) that can be stated by extracting a large clique from a specific graph of elementary constraints.

A maximum clique is a clique of maximum size, a clique being a subset of vertices such that each vertex is connected to all other vertices of the clique.

3.7.149 Maximum number of occurrences

- MAX_VALUE.

A constraint that restricts the maximum number of times that a given value is taken.
3. DESCRIPTION OF THE CATALOGUE

3.7.150  ➙\textbf{maxint} ➙

- DEEPEST\_VALLEY,
- MIN\_N,
- MINIMUM,
- MINIMUM\_MODULO.

A constraint that uses maxint in its definition in terms of graph properties or in terms of automata. maxint is the largest integer that can be represented on a machine.

3.7.151  ➙\textbf{Metro} ➙

- LEQ\_CST.

A constraint that can be used for modelling the metro problem, i.e., finding the shortest distance from a given metro station to all other stations of the network.

Given an undirected graph $G = (V, E)$, with a non-negative distance attached to each edge of $E$, a conjunction of LEQ\_CST constraints was used by H. Simonis in order to illustrate how propagation for such a conjunction simulates a naïve version of Dijkstra algorithm for computing the shortest distance from a given vertex $v_s$ of $V$ to all other vertices. The potential source of inefficiency comes from the fact that, depending on the scheduling policy of the underlying constraint engine, an inequality constraint can be reconsidered several times before reaching the fixed point. The problem was modelled in the following way:

- To each vertex $v_i \in V$ we associate a distance variable $D_i$, which represents the domain range of the distance between vertex $v_i$ and vertex $v_s$.

- To each edge $(v_i, v_j) \in E$ we impose two inequality constraints $D_i \leq D_j + d_{i,j}$ and $D_j \leq D_i + d_{i,j}$, where $d_{i,j}$ corresponds to the distance attached to edge $(v_i, v_j)$. This restricts the maximum difference between the distances variables associated with the two extremities of edge $(v_i, v_j)$.

- Finally, we set the distance variable attached to vertex $v_s$ to 0. Propagating the inequalities constraints by using arc-consistency enforces the maximum value of each distance variable $D_i$ to be equal to the shortest distance from vertex $v_i$ to $v_s$ when the fixed point is reached.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

Figure 3.42: A metro map composed of four lines (a blue, a pink, a green and a yellow line) and the corresponding minimum and maximum values of the distance variables attached to each station, under the assumptions (1) that the distance attached to each connection is equal to 1 and (2) that we compute the shortest path from station \( i \) (in red); the font size used for displaying the bounds of a distance variable is inversely proportional to the length of the shortest path to station \( i \).

Figure 3.42 illustrates this problem on a metro map composed of four lines and 18 stations respectively labelled by \( \text{a, b, ... , r} \). Its assumes that the distance associated with each connection is equal to 1. The figure displays the status (i.e., the minimum and maximum values) of the distance variables under the assumption that we want to compute the shortest path from station \( i \). The inequalities constraints between the distance variables \( D_a, D_b, \ldots, D_r \) corresponding to this metro map are:

- (constraints attached to the connections of the blue metro line)
  - \( D_a \leq D_b + 1 \), \( D_b \leq D_a + 1 \),
  - \( D_b \leq D_c + 1 \), \( D_c \leq D_b + 1 \),

3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

- MINIMUM_GREATER_THAN,
- MINIMUM_MODULO,
- NEXT_ELEMENT,
- NEXT_GREATER_ELEMENT,
- OPEN_MAXIMUM,
- OPEN_MINIMUM.

A constraint for which the definition involves the notion of minimum.

3.7.153 ▼Minimum cost flow «

- SOFT_ALLDIFFERENT_CTR,
- SOFTSAME_VAR.

A constraint for which there is a filtering algorithm based on an algorithm that finds a minimum cost flow in a graph. This graph is usually constructed from the variables of the constraint as well as from their potential values. Figure 3.43 illustrates the minimum cost flow model used for the SOFTSAME_VAR constraint. The demand and the capacity of the arcs are depicted by an interval on top of the corresponding arcs. The weight is given after that interval: a weight of 0 (respectively 1) is depicted by a dotted (respectively plain) arc. Weights of 1 are assigned to arcs linking two values since they model the correction of a discrepancy between variables $x_1$, $x_2$, $x_3$ and variables $y_1$, $y_2$, $y_3$. Blue arcs represent the feasible flow corresponding to the solution SOFTSAME_VAR(2, ⟨1, 3, 3⟩, ⟨2, 2, 3⟩).

3.7.154  \textbf{Minimum task duration}  

\textbf{[7 CONS]}

- \texttt{COLOURED.CUMULATIVE},
- \texttt{COLOURED.CUMULATIVES},
- \texttt{CUMULATIVE},
- \texttt{CUMULATIVE.PRODUCT},
- \texttt{CUMULATIVES},
- \texttt{DISJUNCTIVE},
- \texttt{TASKS.INTERSECTION}.

A constraint involving one or several collections of tasks, where each task has an origin $o$, a duration $d$ and an end $e$ linked by the constraint $e = o + d$. From now on we assume that bound-consistency was achieved on constraint $e = o + d$. Assuming that the minimum duration of the task is always equal to the minimum value $d$ is not quite true and can weaken reasoning as illustrated by the following examples:

- Using interval $[o, o + d]$ as the compulsory part of the task is an underestimation of the compulsory part when the quantity $o + d$ is strictly less than the earliest end $e$ of the task. To avoid that underestimation one should always use $[o, e]$ when the duration of the task is not fixed. The problem is that, depending where the task starts, its duration is not necessarily equal to its minimum value as the task has to finish at least at time $e$.

- Using the smallest duration $d$ for computing the minimum intersection of the task with a fixed interval under the hypothesis that the task starts at a given instant may also leads to an underestimation for the same reason. Figure 3.44 shows how the minimum duration of a task varies with respect to the origin of the task and to constraint $e = o + d$. 

3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

Figure 3.44: The two cases (A) and (B) showing how the minimum duration of a task varies wrt its origin $o$ and to constraint $e = o + d$. 

CASE (A): $o + d \geq e$

CASE (B): $o + d < e$
3.7.155 ▼Minimum feedback vertex set ➔

- CUTSET.

Denotes that a constraint is related to the minimum feedback vertex set problem: given a connected graph \( G = (V, E) \), find out a minimum cardinality subset \( V' \) of \( V \) such that the graph \( G' \) induced by \( V \setminus V' \) does not contain any cycle. A survey on the feedback vertex set problem is given in [176].

3.7.156 ▼Minimum hitting set cardinality ➔

- NVALUE.

Denotes that, by reduction to the problem of finding the cardinality of a minimum hitting set, deciding whether a constraint has a solution or not, or getting a sharp lower bound for one of its arguments, was shown to be NP-hard. The cardinality of a minimum hitting set problem can be described as follows: given a collection \( C \) of subsets of a set \( S \), find the minimum cardinality of \( S' \subseteq S \) such that \( S' \) contains at least one element from each subset in \( C \).

3.7.157 ▼Minimum number of occurrences ➔

- MIN_NVALUE.

A constraint that restricts the minimum number of times that a given value is taken.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

Denotes that the arc constraint associated with a given constraint mentions the function `mod`.

3.7.159 ▼ Multi-site employee scheduling with calendar constraints → [3 CONS]

- CALENDAR,
- DIFFN,
- GEOST.

An international software company located in France and Germany has offices in Paris, Lyon and Marseille as well as in Berlin, Hamburg and Munich. Four types of activities are performed by its employees, namely (1) software development, (2) software deployment, (3) software training courses, and (4) business trips. Software developments tasks and training courses are performed within company’s offices, while software deployment and business trips are done at customer’s sites. Scheduling activities to employees is typically done on a yearly basis from Jan. 1 of current year to Apr. 30 of next year. Considering the first four months of the next year is done in order to absorb eventual overload and to anticipate the effect of Christmas and winter vacations. Without loss of generality we assume that our planning period is from Jan. 1, 2010 to Apr. 30, 2011. The level of granularity is the individual day. Since employees are located on different home sites, one has to consider the following holidays:

- Public holidays that do not fall on a weekend (i.e., a Saturday or a Sunday) are listed below.
3. DESCRIPTION OF THE CATALOGUE

- In the context of Germany, *regional holidays* related to the federal state where a home site is situated. For Munich (Bavaria) we have the following additional days off, that all fall outside a weekend: Jan. 6, June 3, Nov. 1 in 2010 and Jan. 6 in 2011.

- Each home site is closed for a known fixed period of nine consecutive days that is located during summer school vacations. In addition each employee has five consecutive days off, a priori known, crossing winter school vacation. Summer and winter school vacations are linked to the country and the area where a home site is located. Regarding school vacations, France is partitioned in three zones, while Germany is divided in 16 federal states. Paris, Lyon and Marseille are located in distinct zones, while Berlin, Hamburg and Munich are situated in different federal states. *Summer vacations periods* are:

  - From July 7, 2010 to Aug. 21, 2010 in Berlin.
  - From July 8, 2010 to Aug. 18, 2010 in Hamburg.

*Winter vacations periods* are:

The goal is to schedule a given set of known tasks to employees in such a way that each employee has 30 days off in 2010, some of them corresponding to the mandatory public and regional holidays depending of the home site of an employee. Each task has:

1. A *type* (i.e., software development, software deployment, software training courses, and business trips).

3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3. A latest end in 2010. Tasks which cannot be allocated with respect to their 2010 time windows must be scheduled in early 2011, i.e., from Jan. 1, 2011 to Apr. 30, 2011.

4. A duration.

5. A number of required employees.

6. A list of home sites qualified to perform the task.

Business trips, training courses and software deployment cannot be interrupted at all, while software development tasks cannot be interrupted by summer vacation. Business trips have to start on a Monday or a Tuesday since the general company policy is to prevent people staying abroad during weekends. Each task has to be allocated to employees, which are all based on the same home site, in such a way that the same set of employees takes care of the task from its start towards its completion. Each employee has:

1. A home site (i.e., Paris, Lyon, Marseille, Berlin, Hamburg or Munich).
2. A five days period of winter 2010 vacation.
3. A five days period of winter 2011 vacation.
4. A list of task types (i.e., software development, software deployment, software training courses, business trips) it can handle.

Finally, each home site has a nine days period of summer 2010 vacation where the home site is closed down.

Denotes a constraint defined by a graph constraint for which the final graph does not have any loop.

3.7.1.64  n-Amazons  [4 CONS]

- ALLDIFFERENT,
- ALLDIFFERENT_CST,
- INVERSE,
- SMOOTH.

A constraint that can be used for modelling the n-Amazons problem. Place n Amazons on an n by n chessboard in such a way that no Amazon attacks another. We say that two columns (respectively two rows) of a chessboard are almost adjacent if and only if the two columns (respectively the two rows) are separated by a single column (respectively a single row). Two Amazons attack each other if at least one of the following conditions holds:

1. They are located on the same column, on the same row or on the same diagonal.
2. They are located either on adjacent columns and on almost adjacent rows, or on almost adjacent columns and on adjacent rows.

As shown by these conditions, an Amazon combines the movements of a queen and of a knight. Figure 3.45 illustrates the movements of an Amazon. The n-Amazons problem has no solution when n is smaller than 10.

We now show how to model the n-Amazons problem with six global constraints. We start from the model that is used for the n-queens problem. We associate to the i-th column of the chessboard a domain variable $X_i$ that gives the row number where the corresponding queen is located.

- The fact that two Amazons should not be located on the same column, on the same row or on the same diagonal can be modelled as the conjunction of three ALLDIFFERENT constraints:
with the three ALLDIFFERENT\((X_1, X_2 + 1, \ldots, X_n + n - 1)\) for the upper-left to lower-right diagonals,

- ALLDIFFERENT\((X_1, X_2, \ldots, X_n)\) for the rows,

- ALLDIFFERENT\((X_1 + n - 1, X_2 + n - 2, \ldots, X_n)\) for the lower-right to upper-left diagonals.

- The fact that two Amazons cannot both be located on adjacent columns and on almost adjacent rows can be modelled by disequality constraints of the form \(|X_i - X_{i+1}| \neq 2\) (1 ≤ i ≤ n - 1).

- Similarly, the fact that two Amazons cannot both be located on almost adjacent columns and on adjacent rows can be modelled by disequality constraints of the form \(|X_i - X_{i+2}| \neq 1\) (1 ≤ i ≤ n - 2). For a reason that will become clear later on, we rewrite this set of disequalities as \(|X_{2i+1} - X_{2i+3}| \neq 1\) (0 ≤ i ≤ \([n-3]\)) and \(|X_{2i} - X_{2i+2}| \neq 1\) (1 ≤ i ≤ \([n-2]\)).

If we combine the constraints of the form \(|X_i - X_{i+1}| \neq 2\) (1 ≤ i ≤ n - 1) with the three ALLDIFFERENT constraints we get the conjunction of constraints \(X_i - X_{i+1} \neq 0 \land |X_i - X_{i+1}| \neq 1 \land |X_i - X_{i+1}| \neq 2\) (1 ≤ i ≤ n - 1). This conjunction of three disequalities can be expressed as a single inequality of the form \(|X_i - X_{i+1}| > 2\) (1 ≤ i ≤ n - 1). Furthermore all these inequalities can be combined into a single SMOOTH constraint of the form SMOOTH(n - 1, 2, \(\langle X_1, X_2, \ldots, X_n \rangle\)).\(^{15}\) Similarly we get the constraints \(|X_{2i+1} - X_{2i+3}| > 2\) (0 ≤ i ≤ \([n-3]\)) and \(|X_{2i} - X_{2i+2}| > 2\) (1 ≤ i ≤ \([n-2]\)). Again we obtain two SMOOTH constraints of the form SMOOTH(\([n-1]\), 2, \(\langle X_1, X_3, \ldots, X_{n-1+n \mod 2} \rangle\)) and SMOOTH(\([n-2]\), 2, \(\langle X_2, X_4, \ldots, X_{n-n \mod 2} \rangle\)).

Finally, the INVERSE constraint can also be used as a channelling constraint if we want to create an additional variable for each row. This may be the case, for example,

![Figure 3.45: Illustration of the moves of an Amazon: moves labelled by 1 correspond to queen’s moves, while moves labelled by 2 correspond to knight’s moves](image)

\(^{15}\)Since we enforce for all pairs of consecutive variables \(X_i, X_{i+1}\) (1 ≤ i ≤ n - 1) the constraint \(|X_i - X_{i+1}| > 2\), the name SMOOTH seems odd. However the name SMOOTH stands from the situation where the number of inequalities constraints should be minimised.
if we want to have a heuristic for selecting first the column or the row that has the smallest number of possibilities.

Figure 3.46: The unique solution to the 10-Amazons problem (modulo symmetries)

Figure 3.46 shows the unique solution, modulo symmetries, to the \( n \)-Amazons problem for \( n = 10 \). We have the following conjunction of constraints:

- **ALLDIFFERENT(CST)** \( (\langle \text{var} - X_1 \text{ cst} - 0, \text{var} - X_2 \text{ cst} - 1, \text{var} - X_3 \text{ cst} - 2, \text{var} - X_4 \text{ cst} - 3, \text{var} - X_5 \text{ cst} - 4, \text{var} - X_6 \text{ cst} - 5, \text{var} - X_7 \text{ cst} - 6, \text{var} - X_8 \text{ cst} - 7, \text{var} - X_9 \text{ cst} - 8, \text{var} - X_{10} \text{ cst} - 9 \rangle) \),

- **ALLDIFFERENT** \( (X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, X_9, X_{10}) \),

- **ALLDIFFERENT(CST)** \( (\langle \text{var} - X_1 \text{ cst} - 9, \text{var} - X_2 \text{ cst} - 8, \text{var} - X_3 \text{ cst} - 7, \text{var} - X_4 \text{ cst} - 6, \text{var} - X_5 \text{ cst} - 5, \text{var} - X_6 \text{ cst} - 4, \text{var} - X_7 \text{ cst} - 3, \text{var} - X_8 \text{ cst} - 2, \text{var} - X_9 \text{ cst} - 1, \text{var} - X_{10} \text{ cst} - 0 \rangle) \),

- **SMOOTH** \( (9, 2, (X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, X_9, X_{10})) \),

- **SMOOTH** \( (4, 2, (X_1, X_3, X_5, X_7, X_9)) \),

- **SMOOTH** \( (4, 2, (X_2, X_4, X_6, X_8, X_{10})) \).
3. DESCRIPTION OF THE CATALOGUE

3.7.165  **n-queens**

- ALLDIFFERENT,
- ALLDIFFERENT_CST,
- INVERSE.

A constraint that can be used for modelling the \textit{n-queen} problem. Place \(n\) queens on an \(n\) by \(n\) chessboard in such a way that no queen attacks another. Two queens attack each other if they are located on the same column, on the same row or on the same diagonal. A constructive method for arbitrary \(n > 3\) was first given in [171]. An effective heuristic for the \textit{n-queen} problem was given in [240]. It consists of starting to place the queens in the centre of the chessboard so that they eliminate the maximum number of potential positions.

3.7.166  **Non-deterministic automaton**

- AMONG,
- CHANGE,
- SMOOTH.

A constraint for which the catalogue provides a non-deterministic automaton without counters and without array of counters. For the mentioned constraints it turn out that non-determinism is due to the fact that we introduce transitions labelled by the potential values of a counting variable to a single accepting state (i.e., see Figures 5.63, 5.162, and 5.738).
### 3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

- OVERLAP_SBOXES,
- TWO_LAYER_EDGE_CROSSING.

A constraint for which a better description is needed (i.e., TWO_LAYER_EDGE_CROSSING), or a constraint for which the definition
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

needs to be checked: the eight topological relations of RCC-8 should be mutually incompatible, which is not the case with the current logic based definitions.

3.7.172 One succ

Denotes that a constraint is defined by a single graph constraint such that:

- All the vertices of its initial graph belong to the final graph,
- All the vertices of its final graph have exactly one successor.
A constraint for which the set of solutions can be recognised by a so called open automaton. An open automaton is a finite deterministic automaton taking as input a sequence of variables $V_1 V_2 \ldots V_n$ as well as a sequence of 0-1 variables $B_1 B_2 \ldots B_n$. A variable $B_i$ ($1 \leq i \leq n$) set to value 0 means that the corresponding variable $V_i$ is removed from the sequence of variables $V_1 V_2 \ldots V_n$.

Consider a constraint $C$ for which we already have a finite deterministic automaton $A$ that only accepts the set of solutions to $C$. Constructing the finite deterministic automaton $A'$ that only recognises the set of solutions to the open version of constraint $C$ can be done in a systematic way from the automaton $A$. First, to each transition of $A$ we add the fact the corresponding Boolean variable must also be equal to 1. Second, to each state of $A$ we add a loop transition for which the corresponding Boolean variable $B_i$ ($1 \leq i \leq n$) must be equal to 0 (since variable $V_i$ is ignored, we stay within the same state). Figure 3.47 illustrates this construction in the context of the $\text{MINIMUM}$ constraint and of its open counterpart, the $\text{OPEN_MINIMUM}$ constraint.

![Figure 3.47: Constructing the (B) automaton of the OPEN_MINIMUM($\{\text{MIN}, \langle V_1, B_1, V_2, B_2, \ldots, V_n, B_n \rangle \}$) constraint from the (A) automaton of the MINIMUM($\{\text{MIN}, \langle V_1, V_2, \ldots, V_n \rangle \}$) constraint (an accepting state is denoted graphically by a double circle)]
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.174 Open constraint

- OPEN_ALLDIFFERENT,
- OPEN_AMONG,
- OPEN_ATLEAST,
- OPEN_ATMOST,
- OPEN_GLOBAL_CARDINALITY,
- OPEN_GLOBAL_CARDINALITY_LOW_UP,
- OPEN_MAXIMUM,
- OPEN_MINIMUM,
- SIZE_MAX_STARTING_SEQ_ALLDIFFERENT.

A constraint from which all its variables are not completely known when the constraint is posted [438]. In many situations, such as configuration, planning, or scheduling of process dependant activities, the variables of a constraint are not completely known initially when the constraint is posted. Instead, they are revealed during the search process [23, 172, 173]. In practice, an additional argument of the constraint (a set variable or a set of 0-1 variables) provides the initial set of potential variables (the lower bound in the context of a set variable). In Bartak’s model [23], an open constraint admits a sequence of domain variables \( V_1 V_2 \ldots V_m \) \((m \geq 1)\) as well as an additional variable \( C \) which gives the index of the last variable that effectively belongs to the constraint (i.e., variables \( V_{C+1}, V_{C+2}, \ldots, V_m \) are discarded). This is the case, for example, for the SIZE_MAX_STARTING_SEQ_ALLDIFFERENT constraint.

Within the context of open constraints, the notion of contractibility was introduced in [283] in order to characterise a global constraint for which any pruning rule that removes a value from one of its variable (or which enforces any type of condition) can be reused in the context of the corresponding open global constraint (i.e., the pruning rule still makes valid deductions in the context of the open case). Intuitively, many global constraints which impose a kind of at most condition are contractible, while this is typically not the case for global constraints which enforce a kind of at least condition.

See also the keywords open automaton constraint, contractible, and extensible.

- TWO_ORTH_DO_NOT_OVERLAP,
- TWO_ORTH_INCLUDE.

Figure 3.48: Illustration of the notion of orthotope for various number of dimensions \( n \)

A constraint involving orthotopes. An orthotope corresponds to the generalisation of the rectangle and box to the \( n \)-dimensional case. In addition its sides are parallel to the axes of the placement space. Figure 3.48 illustrates the notion of orthotope for \( n = 1, 2, 3 \) and 4. A collection usually named ORTHOTOPE, declared as ORTHOTOPE\(_{\text{collection}}\)(ori\(_{\text{dvar}},\) siz\(_{\text{dvar}},\) end\(_{\text{dvar}}\)), defines for each dimension \( d \) (with \( d \in [1, n]\)) the coordinate of its lower corner, the size and the coordinate of its upper corner in dimension \( d \). Figure 3.49 illustrates the representation of an orthotope for \( n = 2 \).

Figure 3.49: Representation of an orthotope when the number of dimensions \( n = 2 \) in term of the collection ORTHOTOPE\(_{\text{collection}}\)(ori\(_{\text{dvar}},\) siz\(_{\text{dvar}},\) end\(_{\text{dvar}}\))
3.7.177  • Overlapping alldifferent ➔

• K_ALLDIFFERENT.

A constraint expressing several ALLDIFFERENT constraints having some variables in common.

3.7.178  • Pair ➔

• CHANGE_PAIR,
• NPAIR,

• TWIN.

A constraint involving a collection of pairs of variables.

3.7.179  • Packing almost squares ➔

• DIFFN,

• GEOST.

Denotes that a constraint can be used for solving the packing almost squares problem: tile a rectangle for which sides are consecutive integers by rectangles of size $1 \times 2, 2 \times 3, \ldots, n \times (n + 1)$ which can be rotated by 90 degrees. The problem is described in http://www.stetson.edu/~efriedma/almost/. Since there does not always exist a tiling, one can also consider a variant where the goal is to find the rectangle with minimal area. Figure 3.50 provides a solution for $n = 26$ found by H. Simonis.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.180 ▶ Pallet loading ◀

A constraint that can be used for modelling the pallet loading problem. The pallet loading problem consists of packing a maximum number of identical rectangular boxes onto a rectangular pallet in such a way that boxes are placed with their edges parallel to the edges of the pallet. The problem often arises in distribution, when many boxes must be shipped and an increase of the number of boxes on a pallet saves costs. Even though the complexity of the problem is not yet known [303], many solutions have been developed over the past years:

- Exact algorithms based on tree search procedures extend a partial solution by positioning a new box according to different heuristics. One of the most used heuristics is the so called G4 heuristic [384] which recursively divides the placement space into four huge rectangles. Beside the use of an appropriate heuristic, the key point is the use of upper bounds on the maximum number of boxes that can be packed. Some bounds like the Barnes [20] and the Keber [248] bounds consider the geometric structure of the problem. Some other bounds are obtained by solving a linear programming problem [233].

- Approximate algorithms are based on constructive methods (i.e., methods that either divide the pallet into blocks or methods that divide the pallet in a recursive way) or metaheuristics based on genetic algorithms or tabu search [7].

Both in the context of exact and approximates algorithms, the problem is usually first normalised in order to reduce the set of possible solutions [153, 154].
3. DESCRIPTION OF THE CATALOGUE

3.7.181 Partition

- ALLDIFFERENT_PARTITION,
- BALANCE_PARTITION,
- CARDINALITY_ATMOST_PARTITION,
- CHANGE_PARTITION,
- COMMON_PARTITION,
- INSAME_PARTITION,
- K_SAME_PARTITION,
- K_USED_BY_PARTITION,
- NCLASS,
- SAME_PARTITION,
- STRETCH_PATH_PARTITION,
- SOFTSAME_PARTITION_VAR,
- SOFT_USED_BY_PARTITION_VAR,
- USED_BY_PARTITION.

A constraint involving in one of its argument a partitioning of a given finite set of integers.

3.7.182 Path

- BALANCE_PATH,
- PATH,
- PATH_FROM_TO,
- TEMPORAL_PATH.

A constraint allowing for expressing that we search for one or several vertex-disjoint simple paths. Within a digraph a simple path is a set of links that are traversed in the same direction and such that each vertex of the simple path is visited exactly once.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.183 Partridge

- DIFFN
- GEOST.

Denotes that a constraint can be used for solving the Partridge problem: the Partridge problem consists of tiling a square of size $\frac{n(n+1)}{2}$ by $\frac{n(n+1)}{2}$ squares of respective size
- 1 square of size 1,
- 2 squares of size 2,
- \ldots,
- $n$ squares of size $n$.

It was initially proposed by R. Wainwright and is based on the identity $1 \cdot 1^2 + 2 \cdot 2^2 + \cdots + n \cdot n^2 = \left(\frac{n(n+1)}{2}\right)^2$. The problem is described in [http://mathpuzzle.com/partridge.html](http://mathpuzzle.com/partridge.html). Part (A) of Figure 3.51 gives a solution for $n = 12$ found with GEOST [2], while Part (B) provides a solution for $n = 13$ found by S. Hougardy [230].

![Figure 3.51: (A) a solution to the Partridge problem for $n = 12$, and (B) a solution for $n = 13$](image-url)
3.7.184 Pattern sequencing

• CUMULATIVE, CONVEX.

A constraint allowing for expressing the pattern sequencing problem as a single global constraint. The pattern sequencing problem [177] can be described as follows: given a 0-1 matrix in which each column $j \ (1 \leq j \leq p)$ corresponds to a product required by the customers and each row $i \ (1 \leq i \leq c)$ corresponds to the order of a particular customer (The entry $c_{ij}$ is equal to 1 if and only if customer $i$ has ordered some quantity of product $j$), the objective is to find a permutation of the products such that the maximum number of open orders at any point in the sequence is minimised. Order $i$ is open at point $k$ in the production sequence if there is a product required in order $i$ that appears at or before position $k$ in the sequence and also a product that appears at or after position $k$ in the sequence.

3.7.185 Pentomino

• DIFFN,
• GEOST,
• POLYOMINO,
• REGULAR.

A constraint (i.e., POLYOMINO) that can be used to model a pentomino. A pentomino is an arrangement of five unit squares that are joined along their edges.

Also denotes a constraint (i.e., DIFFN, GEOST, REGULAR) that can be used for solving tiling problems involving pentominoes. For example, the GEOST and REGULAR constraints where respectively used in [42] and in [257] to solve such tiling problems.

Figure 3.52 presents a tiling of a rectangle with distinct pentominoes.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.186 ‡ Periodic ➙

- PERIOD,
- PERIOD_EXCEPTION,
- PERIOD_VECTORS.

A constraint that can be used for modelling the fact that we are looking for a sequence that has some kind of periodicity.

3.7.187 ‡ Permutation ➙

- ALLDIFFERENT,
- ALLDIFFERENT_CONSECUTIVE_VALUES,

- SAME_AND_GLOBAL_CARDINALITY_LOW_UP,
- SAME_INTERVAL,
- SAME_MODULO,
- SAME_PARTITION,
- SORT,
- SORT_PERMUTATION,
- SYMMETRIC_ALLDIFFERENT.

A constraint that can be used for modelling a permutation or a specific type or characteristic of a permutation. A permutation is a rearrangement of elements, where none are changed, added or lost.
### 3.7.188 Permutation channel

- **INVERSE.**

A constraint that allows for modelling the link between a *permutation* and its *inverse permutation*. A *permutation* is a rearrangement of *n* distinct integers between 1 and *n*, where none are changed, added or lost. An *inverse permutation* is a permutation in which each number and the number of its position are swapped.

### 3.7.189 Phi-tree

- **DISJUNCTIVE,**

- **CUMULATIVE.**

A constraint for which one of its filtering algorithms uses a balanced binary tree in order to efficiently evaluate the maximum or minimum value of a formula over all possible subsets of tasks *Ω* of a given set of tasks *Φ*. *Φ*-trees were introduced by P. Vilím, first in the context of unary resources in [443] and in [444, pages 37–40], and later on in the context of cumulative resources [446, 445]. Without loss of generality, let us sketch the main idea behind a *Φ*-tree in the context of a cumulative resource of capacity *C*. For this purpose we follow the description given in [446].

Given a set of tasks *Φ* where each task has an *earliest possible start*, a *latest possible end*, a *duration* and a *resource consumption*, assume we need to evaluate the *earliest completion time* over all tasks of *Φ* under the hypothesis that we should not exceed the maximum resource capacity *C*. Let us first introduce some notations:

- *Ω* denotes any non-empty subset of tasks of *Φ*.
- *est*ₐ is the minimum over the earliest starts of the tasks in *Ω*.
- *e*ₐ is the sum of the surfaces (i.e., the product of the duration by the resource consumption) of the tasks in *Ω*.

A common estimation of the earliest completion time over all tasks of *Φ* is

\[
\max_{Ω \subseteq Φ} \left\{ est_Ω + \left[ \frac{e_Ω}{C} \right] \right\}
\]

which can be rewritten as

\[
\left\lceil \frac{\max_{Ω \subseteq Φ} (est_Ω + e_Ω)}{C} \right\rceil.
\]

The numerator of the last fraction is called the *energy envelope* of the set of tasks *Φ* and the purpose of a *Φ*-tree is to evaluate this quantity efficiently. For a node *n*, let *L(n)* denotes the set of leaves of the sub-tree rooted at *n*. The leaves of the *Φ*-tree correspond
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

![Diagram of Φ-tree associated with four tasks of respective duration and resource consumption](image)

Figure 3.53: Example of Φ-tree associated with four tasks of respective duration and resource consumption $3 \times 4, 1 \times 3, 5 \times 5, 2 \times 4$ and of respective earliest start 1, 3, 8, 9 under the assumption that the maximum capacity of the cumulative resource is equal to 5.

To the tasks of $\Phi$ sorted from left to right by increasing earliest start. Each node $n$ of the $\Phi$-tree records both, the sum of the surfaces of the tasks in $L(n)$, as well as the energy envelope of the tasks in $L(n)$. The sum of the surfaces associated with a non-leaf node $n$ of the tree corresponds to the sum of the surfaces of the children of $n$, while the energy envelope of $n$ is equal to the maximum between on the one hand, the energy envelop of its right child and on the other hand the sum of the energy envelop of its left child and the recorded sum of surfaces of its right child (see [446] for a justification of these recursive formulae). Figure 3.53 illustrates the construction of a $\Phi$-tree associated with four given tasks.
3.7.190  • Phylogeny ➝  

- **STABLE_COMPATIBILITY.**

A constraint inspired by the area of phylogeny. Phylogeny is concerned by the classification of organism based on genetic connections between species.

3.7.191  • Pick-up delivery ➝  

- **CYCLE.**

A constraint that was used for modelling a *pick-up delivery problem*. In a *pick-up delivery problem*, vehicles have to transport loads from origins to destinations without any transhipment at intermediate locations.

3.7.192  • Planarity test ➝  

- **CIRCUIT.**

A constraint that can use the *planarity test* in its filtering algorithm. The *planarity test* determines whether a graph can be embedded in the plane.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.193 Polygon

- DIFFN,

A constraint that can be generalised to handle polygons.

3.7.194 Positioning constraint

- DIFFN.COLUMN,

- VISIBLE,
- ZERO_OR_NOT_ZERO,
- ZERO_OR_NOT_ZERO_VECTORS.

A constraint for which the meaning is not explicitly described in terms of graph properties or in terms of automata or in terms of first order logic.
3.7. Preferences

- COND_LEX_COST
- COND_LEX_GREATER
- COND_LEX_GREATEREQ
- COND_LEX_LESS
- COND_LEX_LESSEQ

A constraint that can be used for modelling preferences.

3.7. Producer-consumer

- CUMULATIVE
- CUMULATIVES

A constraint that can be used for modelling problems where a first set of tasks produces a non-renewable resource, while a second set of tasks consumes this resource so that a limit on the minimum or the maximum stock at each instant is imposed.

Parts (A) and (B) of Figure 3.54 describes the simplest variant of the producer-consumer problem [399] where no negative stock is allowed. Given an initial stock, a first set of tasks (i.e., producers) add instantaneously their respective productions to the stock (when they are finished), and a second set of tasks (i.e., consumers) take instantaneously from the stock (when they start) the amount of non-renewable resource they need. The problem is to schedule these tasks (i.e., fix the end of the producers and fix the start of the consumers) and to fix for each task the quantity it produces or consumes, so that no negative stock occurs. Part (A) of Figure 3.54 describes an instance of such problem where we respectively have 2 producers and 3 consumers. Part (B) depicts the corresponding cumulative view of the problem. At each timepoint the difference between the top line and the top of the cumulated profile gives the amount of available stock at that timepoint.

A fundamental problem with the previous variant of the producer-consumer problem is that it does not allow to handle the fact that a resource is produced or used gradually. Parts (C) and (D) of Figure 3.54 describes a second variant where this is in fact possible. This is achieved by replacing the rectangle associated with a producer by a task with a decreasing height. At a given instant the cumulated quantity produced by a producer is the difference between the height of that task at its starting time and the height of that task at the considered instant. Conversely a consumer is modelled by a task with an increasing height. At a particular timepoint the cumulated quantity used by a consumer task is the difference between the height of that task at its end...

A constraint for which the meaning is completely captured by one or more functional dependencies. The negation of such constraints can be directly expressed as a disjunction between the different functional dependencies. We illustrate this point on different examples:

- The negation of the NVALUE\((n, (v_1, v_2, \ldots, v_m))\) constraint is defined by NVALUE\((p, (v_1, v_2, \ldots, v_m))\) \land n \neq p.

- The negation of the COMMON\((n_1, n_2, (u_1, u_2, \ldots, u_p), (v_1, v_2, \ldots, v_q))\) constraint is defined by COMMON\((m_1, m_2, (u_1, u_2, \ldots, u_p), (v_1, v_2, \ldots, v_q))\) \land (n_1 \neq m_1 \lor n_2 \neq m_2).

- The negation of the ELEMENTS\(((\text{index} - i_1) \text{ value} - u_1, (\text{index} - i_2) \text{ value} - u_2, \ldots, (\text{index} - i_n) \text{ value} - u_n), (\text{index} - 1) \text{ value} - v_1, (\text{index} - 2) \text{ value} - v_2, \ldots, (\text{index} - n) \text{ value} - v_n)\) constraint is defined by ELEMENTS\(((\text{index} - i_1) \text{ value} - w_1, (\text{index} - i_2) \text{ value} - w_2, \ldots, (\text{index} - i_n) \text{ value} - w_n), (\text{index} - 1) \text{ value} - v_1, (\text{index} - 2) \text{ value} - v_2, \ldots, (\text{index} - n) \text{ value} - v_n)\) \land (u_1 \neq w_1 \lor u_2 \neq w_2 \lor \cdots \lor u_n \neq w_n).

- The negation of the SORT\(((u_1, u_2, \ldots, u_n), (v_1, v_2, \ldots, v_n))\) constraint is defined by SORT\(((u_1, u_2, \ldots, u_n), (w_1, w_2, \ldots, w_n))\) \land LEX_DIFFERENT\(((v_1, v_2, \ldots, v_n), (w_1, w_2, \ldots, w_n))\).
3. DESCRIPTION OF THE CATALOGUE

3.7.202  Quadtree

• CUMULATIVE,TWO,D.
• DIFFN.

Denotes that, for a given constraint, a quadtree can be used within its filtering algorithm. A quadtree is a hierarchical data structure based on the recursive decomposition of space. Figure 3.55 illustrates the representation of a two-dimensional binary region (A) with a quadtree (C). A region is subdivided into quadrants, subquadrants, and so on (B), until blocks consist entirely of 1s or entirely of 0s.

Figure 3.55: (A) A region, (B) its subdivision in maximal blocks, (C) and the corresponding quadtree

• COVERS_SBOXES,
• DISJOINT_SBOXES,
• EQUAL_SBOXES,
• INSIDE_SBOXES,
• MEET_SBOXES,
• OVERLAP_SBOXES.

Region Connection Calculus (i.e., RCC-8) [349] provides eight topological relations (i.e., disjoint, meet, overlap, equal, covers, coveredby, contains, inside) between two fixed objects such that any two fixed objects are in one and exactly one of these topological relations. Figure 3.56 illustrates the meaning of each topological relation.
Figure 3.56: The eight topological relations of RCC-8 (non-overlapping parts of rectangles $A$ and $B$ are coloured in pink, while overlapping parts are coloured in red)

### 3.7.206 Rectangle clique partition

- **NVECTOR.**

Denotes that, by reduction to the rectangle clique partition problem, deciding whether a constraint has a solution or not was shown to be NP-hard. The rectangle clique partition problem can be described as follows: given a rectangle graph, can its set of vertices be partitioned into $k$ subsets of vertices such that all corresponding induced subgraphs correspond to cliques? A rectangle graph is a graph that can be associated with a set of fixed rectangles whose sides are parallel to the axes of the placement space: to each rectangle corresponds a vertex of the rectangle graph, while to each pair of intersecting rectangles corresponds an edge.

### 3.7.207 Regret based heuristics

- **ELEM, ELEMENT, GLOBAL_CARDINALITY_WITH_COSTS, SUM_CTR.**

Assume you have a discrete optimisation problem where the sum of some cost variables should be minimised, and where the cost variables typically have holes in their domains. In this context a regret based heuristic first selects among the not yet
fixed cost variables, the one with the largest difference between its second smallest value and its smallest value. The idea is to consider first a variable that would cause the biggest increase in cost if it could not be assigned its minimum value.

3.7.208 Regret based heuristics in matrix problems

Assume you have a discrete optimisation problem involving a matrix $M$ of decision variables such that there is a cost variable attached to each row of $M$. Moreover assume that the cost associated with each row corresponds to a sum of elementary costs connected with each decision variable of the same row (e.g., we have a SUM_CTR or a GLOBAL_CARDINALITY_WITH_COSTS constraint on each row of $M$). Now, suppose we want to use a heuristic for fixing the decision variables of matrix $M$ row by row. In this context a question is which row to select first. Since the cost variable $c_r$ associated with a row $r$ corresponds to a sum of elementary costs, it is very unlikely that the cost variable $c_r$ has a hole in its domain. Consequently, we cannot any more use a conventional regret based heuristic which relies on the fact that we have holes in the domains of the cost variables. We still want to use the idea of finding the variable that would potentially cause the biggest increase in cost in the worst case, i.e. if it would have to be assigned to its maximum value. For this purpose we consider the variable for which the difference between its largest value and its smallest value is maximal. In our context we select the row $r$ for which the corresponding cost variable maximises such difference. First we enumerate in increasing value order on the cost variable associated with row $r$. Second we fix all decision variables of row $r$ using, for example, the heuristic described in labelling by increasing cost. Using such cost based heuristics has both some advantage and some drawback:

- The big potential advantage is that, if we can find a first solution at all, then this solution should have a rather small overall cost.

- The potential drawback is that, depending on how strong the row constraints propagate from the maximum total cost associated with a row back to the decision variables of the row, it may be very difficult to find a feasible solution (since assigning the cost variable of a row to its minimum value potentially creates an infeasible problem for which we need to develop a large search tree).
Reified automaton constraint

A constraint $C(V_1, V_2, \ldots, V_n)$ for which the reified version can be mechanically constructed from the finite deterministic automaton $A^C$ that only accepts the set of solutions to constraint $C$. This is done by deriving from $A^C$ a so called reified automaton $A^{\neg C}$ by:

- First, adding a 0-1 variable $B$ in front of the sequence of variables $V_1, V_2, \ldots, V_n$. This new sequence of variables will be passed to the reified automaton $A^{\neg C}$. 

- AND,

• Second, constructing from $A^C$ the automaton $A_{\neg C}$ that only recognises non-solutions to constraint $C$.

• Third, building from the two automata $A^C$ and $A_{\neg C}$ the automaton $A^{C\neg C}$. This is done by:
  1. Creating the initial state $s$ of $A^{C\neg C}$.
  2. Adding a transition labelled by value 1 from $s$ to the initial state of $A^C$.
  3. Adding a transition labelled by value 0 from $s$ to the initial state of $A_{\neg C}$.

Figure 3.57: (A) The automaton for recognising the solutions to the \textsc{global\_contiguity} constraint; (B) the automaton for recognising the non-solutions to the \textsc{global\_contiguity} constraint; (C) the automaton for the reified \textsc{global\_contiguity} constraint; within an automaton an initial state is indicated by an arc coming from no state and an accepting state is denoted graphically by a double circle.

Figure 3.57 illustrates the construction of a reified automaton in the context of the \textsc{global\_contiguity} constraint. Part (A) recalls the automaton that only recognises the solutions to the \textsc{global\_contiguity} constraint. Assuming the same alphabet \{0, 1\}, Part (B) provides the automaton that only recognises the non-solutions to the \textsc{global\_contiguity} constraint. Finally, Part (C) depicts the reified automaton constructed from the two automata given in parts (A) and (B).
3.7.210  ▶Reified constraint  ➔

• IN_INTERVAL_REIFIED (reified version of IN_INTERVAL).

The reified version \( CR \) of a given constraint \( C \), where \( CR \) has as arguments all arguments of \( C \) plus one extra 0-1 variable. This 0-1 variable is set to 1 when constraint \( C \) holds, and 0 otherwise. Note that constraint \( CR \) inherits from all restrictions of constraint \( C \) (i.e., incorrect parameters for constraint \( C \) are also incorrect for constraint \( CR \)). Within the context of linear programming the extra 0-1 variable is often called an \textit{indicator variable}.

It was shown in \cite{36} how to reify a global constraint by reformulating it as a conjunction of \textit{pure functional dependency constraints} together with a constraint that can be easily reified (e.g., an automaton with or without counter, or a Boolean combination of linear arithmetic equalities and inequalities and 0-1 variables).

3.7.211  ▶Relation  ➔

• IN_RELATION, • SYMMETRIC_CARDINALITY, • SYMMETRIC_GCC.

A constraint that allows for representing the access to an element of a \textit{relation} or to model a \textit{relation}. A \textit{relation} is a subset of the product of several finite sets.

3.7.212  ▶Relaxation  ➔

• ALLEQUAL_MIN_CTR, • SOFT_ALLEQUAL_MIN_VAR,
• ALLDIFFERENT_CTR, • SOFT_ALLDIFFERENT_VAR,
• DIFFN, • SOFT_ALLDIFFERENT_CTR,
• GEOST, • SOFT_ALLDIFFERENT_VAR,
• RELAXED_SLIDING_SUM, • SOFT_ALLEQUAL_MAX_VAR,
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

- SUM_OF_WEIGHTS_OF_DISTINCT_VALUES,
- WEIGHTED_PARTIAL_ALLDIFF.

Denotes that a constraint allows for specifying a partial degree of satisfaction. For the constraints DIFFN and GEOST see the keyword Relaxation dimension.

3.7.213 ▼Relaxation dimension ➔ [2 CONS]

- DIFFN,
- GEOST.

A constraint that allows the modelling of constraint relaxation in the context of placement problems. This is achieved by adding an extra dimension to the placement space where objects that are really considered are in the foreground, while objects that are discarded are rejected into the background. As a concrete example, consider a slight modification of the data of the task assignment and scheduling problem that is described at the keyword entry assigning and scheduling tasks that run in parallel. In this problem the four nurses are all not available during the time periods [0, 0], [7, 7], [12, 12] and [22, 22]. We now rather consider the following unavailability periods [0, 0], [8, 8], [12, 12] and [22, 22]. Under this new hypothesis we cannot anymore schedule all the five surgery tasks \( t_1, t_2, t_3, t_4 \) and \( t_5 \), i.e., we get a no solution answer if we use the model described in assigning and scheduling tasks that run in parallel. In this model we are using a two-dimensional GEOST constraint, where the first and second dimensions respectively correspond to the time and resource axes. Now, in order to permit relaxation, we introduce a third dimension, a relaxation dimension. The idea is to map each task to a parallelepiped for which the size in the relaxation dimension is equal to one. In addition, the coordinate of a parallelepiped in the relaxation dimension is a variable taking its value in the interval \([1, n]\), where \( n \) represents the number of operations to schedule (i.e., for each surgery task \( t_i \) \( 1 \leq i \leq n = 5 \)) we create a coordinate variable \( r_i \) where \( r \) stands for relaxation. Then, all parallelepipeds for which the coordinate in the relaxation dimension is set to 1 correspond to surgery tasks that are effectively scheduled, while all other parallelepipeds represent surgery tasks that are discarded. On the one hand, this model allows the direct expression of relaxation right from the beginning without introducing any extra soft constraint and without dynamically adding
any constraint during search. On the other hand, a disadvantage is that the model does not directly consider an optimisation criterion like, for example, the maximum number of tasks effectively scheduled, or the sum of the durations of the tasks effectively done; this can be modelled using extra constraints but this does not provide sharp bounds on the optimisation criterion. Nevertheless, this gives a compact model, especially in the context where additional constraints complicate the computation of a sharp bound. Going back to the example described at the keyword entry assigning and scheduling tasks that run in parallel, we get the following three-dimensional \textit{GEOST} constraint:

![Constraint Table]

\textbf{Figure 3.58} depicts a solution to the problem corresponding to the assignment

\begin{verbatim}
<table>
<thead>
<tr>
<th>tasks</th>
<th>origin</th>
<th>relaxation</th>
<th>anaesthetist</th>
<th>surgeon</th>
<th>nurse</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>a1=9</td>
<td>r1=1</td>
<td>a1=1</td>
<td>s1=4</td>
<td>n1=5</td>
</tr>
<tr>
<td>t2</td>
<td>a2=0</td>
<td>r2=2</td>
<td>a2=2</td>
<td>s2=4</td>
<td>n2=8</td>
</tr>
<tr>
<td>t3</td>
<td>a3=2</td>
<td>r3=1</td>
<td>a3=1</td>
<td>s31=3</td>
<td>n31=5</td>
</tr>
<tr>
<td>t4</td>
<td>a4=17</td>
<td>r4=1</td>
<td>a4=1</td>
<td>s4=4</td>
<td>n41=5</td>
</tr>
<tr>
<td>t5</td>
<td>a5=16</td>
<td>r5=1</td>
<td>a5=2</td>
<td>s5=3</td>
<td>n5=8</td>
</tr>
</tbody>
</table>
\end{verbatim}

During search, the relaxation variables \( r_1, r_2, r_3, r_4, r_5 \) are first set to value one (i.e., the corresponding operations are scheduled) and then, upon backtracking, assigned to any value greater than one (i.e., there is no backtrack on the values that are greater than one since we just want to reject an operation into the background).
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

3.7.2  **Resource constraint**

A constraint restricting the utilisation of a resource. The utilisation of a resource is computed from all items that are assigned to that resource.

- DEEPEST_VALLEY,
- EXACTLY,
- FULL_GROUP,
- GROUP,
- GROUP_SKIP_ISOLATED_ITEM,
- HIGHEST_PEAK,
- INFLEXION,
- LENGTH_FIRST_SEQUENCE (LENGTH_LAST_SEQUENCE),
- LONGEST_CHANGE with $\text{CTR} \in \{ =, \neq \}$,
- LONGEST_DECREASING_SEQUENCE (LONGEST_INCREASING_SEQUENCE),
- MAXIMUM,
- MAX_DECREASING_SLOPE (MAX_INCREASING_SLOPE),
- MIN_DECREASING_SLOPE (MIN_INCREASING_SLOPE),
- MIN_SURF_PEAK,
- MIN_WIDTH_PEAK,
- MIN_WIDTH_PLATEAU,
- MIN_WIDTH_VALLEY,
- MINIMUM,
- PEAK,
- SMOOTH,
- VALLEY.

A constraint which has a reverse constraint, where the reverse is defined in the following way. Consider two constraints $\text{ctr}(\text{col}, r_1, \ldots, r_n)$ and $\text{ctr}'(\text{col}, r_1, \ldots, r_n)$ for which, in both cases, the argument $\text{col}$ is a collection of items that functionally determines all the other arguments $r_1, \ldots, r_n$.

The constraint $\text{ctr}'$ is the reverse constraint of constraint $\text{ctr}$ if, for any collection of items $\text{col}$, we have the equivalence $\text{ctr}(\text{col}, r_1, \ldots, r_n) \Leftrightarrow \text{ctr}'(\text{col}^{rev}, r_1, \ldots, r_n)$, where $\text{col}^{rev}$ denotes the collection $\text{col}$ where the items of the collection are reversed. When constraints $\text{ctr}$ and $\text{ctr}'$ are identical we say that constraint $\text{ctr}$ is its own reverse.

The previous enumeration provides the list of reversible constraints where, for each reversible constraint, we give its reverse only when it is different from the original constraint.

Note that if a constraint can be represented by a counter deterministic automaton with a single counter that is only incremented and for which all states are accepting, then by computing the reverse automaton, the corresponding reverse constraint can be mechanically obtained. However note that the reverse automaton may be non-deterministic and may contain $\epsilon$ transitions [297]. Figure 3.59 gives an automaton counting the number of occurrences of words 001 in a sequence and its reverse automaton. Figure 3.60 provides an automaton with one counter and its reverse automaton that has a different number of states.

- STRETCH_PATH_PARTITION,
- VALLEY.

Constrains consecutive variables (possibly not all) of a given collection of domain variables or consecutive vertices of a simple path or a simple circuit. Also a constraint restricting a variable (when fixed to 0 the variable may be omitted) according to consecutive variables of a given collection of domain variables.

3.7.220  ⊙Sequence dependent set-up ⊙ [5 CONS]

- DIFFN,
- DISJUNCTIVE,
- ELEM,
- ELEMENT,
- TEMPORAL_PATH.

Denotes that a constraint can be used for modelling sequence dependent set-up between pairs of tasks. Given,

- a collection of \( n \) tasks \( T \), where each task \( t_i \in T \) (\( 1 \leq i \leq n \)) has an origin \( o_i \), a duration \( d_i \), an end \( e_i \) (\( o_i + d_i = e_i \)) and a machine \( m_i \) to which it will be assigned,
3. DESCRIPTION OF THE CATALOGUE

• and a $n$ by $n$ matrix $M$ of positive integers $\delta_{ij}$, $i, j \in [1, n]$ where $row_i$ denotes the $i^{th}$ row of matrix $M$.

We want to express that $\delta_{ij}$ enforces a minimum distance between the completion of task $t_i \in T$ and the start of task $t_j \in T$ ($i \neq j$) under the hypotheses that (a) both tasks are assigned the same machine (i.e., $m_i = m_j$) and that (b) task $t_j$ immediately follows task $t_i$ (i.e., there is no task $t_k \in T$ ($k \notin \{i, j\}$) such that $m_k = m_i \land e_i \leq o_k \land e_k \leq o_j$). In addition, tasks assigned to the same machine should not overlap (i.e., $\forall i \in [1, n], \forall j \neq i \in [1, n]$ such that $m_i = m_j$ we have $e_i \leq o_j \lor e_j \leq o_i$). We show how to model the previous sequence dependent set-up constraint under the hypothesis that we have a single machine. Without loss of generality we assume that $\delta_{ii} = 0$ for all $i \in [1, n]$.

In a first phase we create for each task $t_i \in T$ ($1 \leq i \leq n$) three additional variables $s_i, g_i$ and $c_i$ that respectively correspond to:

• The successor variable $s_i \in [1, n]$ allows to get the immediate successor of task $t_i$. On the one hand, the assignment $s_i = i$ denotes that task $t_i$ has no immediate successor (i.e., task $t_i$ is the last task running on machine $m_i$). On the other hand, $s_i = j$ ($j \neq i$) denotes that task $t_j$ is the immediate successor of task $t_i$.

• The gap variable $g_i$ represents the size of the gap between the end of task $t_i$ and the start of its immediate successor (the gap is equal to 0 when task $t_i$ has no immediate successor).

• The extended completion variable $c_i$ represents the sum of the end of task $t_i$ and the corresponding gap variable $g_i$ (i.e., $c_i = e_i + g_i$).

In a second phase we post for each task $t_i \in T$ ($1 \leq i \leq n$) the following constraints:

• An ELEMENT($s_i, row_i, g_i$) constraint to make the link between the successor variable $s_i$ and the gap variable $g_i$.

• A SUM_CTR($(e_i, g_i), =, c_i$) constraint.

Finally in a third phase we create a collection of nodes NODES where each item corresponds to a task $t_i \in T$ ($1 \leq i \leq n$) and has an index attribute set to $i$, a start attribute set to $s_i$, a succ attribute set to $o_i$ and an end attribute set to $e_i$. We post a TEMPORAL_PATH(1, NODES) constraint for linking the successor variables, the start variables and the extended completion variables associated with the different tasks. The first argument of the TEMPORAL_PATH constraint forces a single path corresponding to the succession of the different tasks on the unique machine.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.221 Sequencing with release times and deadlines

- CUMULATIVE,
- CUMULATIVES,
- DISJ,
- DISJUNCTIVE.

Denotes that, by reduction to sequencing with release times and deadlines, deciding whether a constraint has a solution or not was shown to be NP-hard. The sequencing with release times and deadlines problem can be described as follows: given a set of non-overlapping tasks and, for each task a length, a release time and a deadline the question is to find a schedule that satisfies all release time constraints and meets all the deadlines.

3.7.222 Set channel

- INVERSE_SET,
- LINK_SET_TOBOOLEANS.

A channelling constraint involving one or several set variables.

3.7.223 Set packing

- K_ALLDIFFERENT.

Denotes that, by reduction to set packing, deciding whether a constraint has a solution or not was shown to be NP-hard. The set packing problem can be described as follows: given a collection $C$ of $n$ finite sets, and a positive integer $m \leq n$, does $C$ contain $m$ disjoint sets?
3. DESCRIPTION OF THE CATALOGUE

3.7.224 **Shikaku**

- **DIFFN**,  
- **GEOST**.

Denotes that a constraint can be used for solving the Shikaku puzzle. Given a rectangular grid, where exactly \( n \) cells contain an integer value, the problem is to tile that grid by \( n \) rectangles in such a way that the surface of each rectangle is equal to the single integer it contains.

![Shikaku Puzzle Example](image)

Figure 3.61: (A) An example of a Shikaku puzzle and (B) its corresponding unique solution.

Parts (A) and (B) of Figure 3.61 respectively show a small instance of such a puzzle and its corresponding unique solution taken from the Nikoli website [https://member.nikoli.com/index.html](https://member.nikoli.com/index.html).

- DISJUNCTIVE_OR_SAME_START
- MULTI_INTER_DISTANCE
- PERIOD
- PERIOD_EXCEPT_0
- SHIFT
- SOFT_CUMULATIVE
- TASKS_INTERSECTION

A constraint useful for the area of scheduling. **Scheduling** is concerned with the allocation or assignment of resources (e.g., manpower, machines, money), over time, to a set of tasks.

3.7.226  

**Scheduling with machine choice, calendars and preemption**  

- CALENDAR
- CUMULATIVES
- DIFFN
- GEOST

A set of constraints that can be used for modelling a scheduling problem where:

- We have tasks that have both to be assigned to machine and time.
- Each task has a fixed duration.
- Machines can run at most one task at a given instant.
- Each machine has its own fixed unavailability periods (i.e., a calendar of unavailability periods).
- An unavailability period that allows (respectively forbids) a task to be interrupted and resumed just after is called *crossable* (respectively *non-crossable*). A task that can be (respectively cannot be) interrupted by a crossable unavailability period is called *resumable* (respectively *non-resumable*).
- We have a precedence constraint between specific pairs of tasks. Each precedence forces that a given task ends before the start of another given task.

This model illustrates the use of two time coordinates systems:
• The first coordinate system, so called the virtual coordinate system, does not consider at all the crossable unavailability periods associated with the different machines. Since resumable tasks can be preempted by machine crossable unavailability, all resource scheduling constraints (i.e., DIFFN, GEOST) are expressed within this first coordinate system. This stands from the fact that resource scheduling constraints like DIFFN or GEOST do not support preemption.

• The second coordinate system, so called the real coordinate system, considers all timepoints whether they correspond or not to crossable unavailability periods. All temporal constraints (i.e., precedence constraints represented by LEQ constraints in this model) are expressed with respect to this second coordinate system.

Consequently, each task has a start and an end that are expressed within the virtual coordinate system as well as within the real coordinate system.

• Each task, whether it is resumable or not, is passed to the resource scheduling constraints as well as to the precedence constraints. In addition, we represent each non-crossable unavailability period as a fixed task that is also passed to the resource scheduling constraints.

• The CALENDAR constraint ensures the link between variables (i.e., the start and the end of the tasks no matter whether they are resumable or not) expressed in these two coordinate systems with respect to the crossable unavailability periods.

We now provide the corresponding detailed model. Given:

1. A set of machines \( \mathcal{M} = \{m_1, m_2, \ldots, m_p\} \), where each machine has a list of fixed unavailability periods. An unavailability \( u_i \) is defined by the following attributes:

   (a) The crossable flag \( c_i \) tells whether unavailability \( u_i \) is crossable \( (c_i = 1) \) or not \( (c_i = 0) \).

   (b) The machine \( r_i \) indicates the machine (i.e., a value in \([1, p]\)) to which unavailability \( u_i \) corresponds (i.e., since different machines may have different unavailability periods).

   (c) The start \( s_i \) of the unavailability \( u_i \) which indicates the first unavailable timepoint of the unavailability.

   (d) The end \( e_i \) of the unavailability \( u_i \) which gives the last unavailable timepoint of the unavailability.

2. A set of tasks \( \mathcal{T} = \{t_1, t_2, \ldots, t_n\} \), where each task \( t_i \) (with \( i \in [1, n] \)) has the following attributes which are all domain variables except the resumable flag and the virtual duration:

   (a) The resumable flag \( r_i \) tells whether task \( t_i \) is resumable \( (r_i = 1) \) or not \( (r_i = 0) \).
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

(b) The machine $m_i$ indicates the machine (i.e., a value in $[1, p]$) to which task $t_i$ will be assigned.

(c) The virtual start $vs_i$ gives the start of task $t_i$ in the virtual coordinate system.

(d) The virtual duration $vd_i$ corresponds to the duration of task $t_i$ without counting the eventual unavailability periods crossed by task $t_i$.

(e) The virtual end $ve_i$ provides the end of task $t_i$ in the virtual coordinate system. We have that $vs_i + vd_i = ve_i$.

(f) The real start $rs_i$ gives the start of task $t_i$ in the real coordinate system.

(g) The real duration $rd_i$ corresponds to the duration of task $t_i$ including the eventual unavailability periods crossed by task $t_i$. When task $t_i$ is non-resumable (i.e., $r_i = 0$) its real duration is equal to its virtual duration (i.e., $rd_i = vd_i$).

(h) The real end $re_i$ indicates the end of task $t_i$ in the real coordinate system. We have that $rs_i + rd_i = re_i$.

The link between the virtual starts (respectively virtual ends) and the real starts (respectively real ends) of the different tasks of $T$ is ensured by a CALENDAR(INSTANTS, MACHINES) constraint. More precisely, for each task $t_i$ (with $i \in [1, n]$), no matter whether it is resumable or not, we create the following items for the collection INSTANTS:

\[
\begin{align*}
\text{machine} & \rightarrow m_i, \quad \text{virtual} \rightarrow vs_i, \quad \text{ireal} \rightarrow rs_i, \quad \text{flagend} \rightarrow 0, \\
\text{machine} & \rightarrow m_i, \quad \text{virtual} \rightarrow ve_i, \quad \text{ireal} \rightarrow re_i, \quad \text{flagend} \rightarrow 1.
\end{align*}
\]

The first item links the virtual and the real start of task $t_i$, while the second item relates the virtual and real ends. For each machine $m_i$ (with $i \in [1, p]$) and its corresponding list of crossable unavailability periods, denoted crossable_unavailability_i, we create the following item of the collection MACHINES:

\[
\text{id} \rightarrow i, \quad \text{cal} \rightarrow \text{crossable_unavailability}_i.
\]

To express the resource constraint, i.e., the fact that two tasks assigned to the same machine should not overlap in time, we use a GEOST(2, OBJECTS, SBOXES) constraint. For each task $t_i$ (with $i \in [1, n]$) we create one item for the OBJECTS collection as well as one item for the SBOXES collection:

\[
\begin{align*}
\text{oid} & \rightarrow i, \quad \text{sid} \rightarrow i, \quad \text{x} \rightarrow \langle m_i, vs_i \rangle, \\
\text{sid} & \rightarrow i, \quad \text{t} \rightarrow \langle 0, 0 \rangle, \quad \text{l} \rightarrow \langle 1, vd_i \rangle.
\end{align*}
\]

The first item corresponds to an object with $i$ as unique identifier, with a rectangular shape identifier $i$ and with $m_i, vs_i$ as the coordinates of its lower left corner. The second item corresponds to a rectangular shape with $i$ as unique identifier, $\langle 0, 0 \rangle$ as shift offset with respect to its lower left corner, and $\langle 1, vd_i \rangle$ as the sizes of the rectangular shape.

Similarly, to express that each task does not overlap a non-crossable unavailability period, we create for each non-crossable unavailability period $i$ one item for the
3. DESCRIPTION OF THE CATALOGUE

OBJECTS collection as well as one item for the SBOXES collection:

\[
\langle \text{oid} - n + i \text{ sid} - n + i \ x - \langle r_i, s_i \rangle \rangle,
\langle \text{sid} - n + i \ t - \langle 0, 0 \rangle \ l - \langle 1, e_i - s_i + 1 \rangle \rangle.
\]

Finally, a precedence constraint between two distinct tasks \( t_i \) and \( t_j \) (with \( i, j \in [1, n] \)) is modelled by an inequality constraint between the real end of task \( t_i \) and the real start of task \( t_j \), namely \( re_i \leq rs_j \). Figure 3.62 provides a toy example of such problem with:

- Four machines, numbered from 1 to 4, where:
  - Machine \( m_1 \) has two crossable unavailability periods respectively corresponding to intervals \([2, 2]\) and \([6, 7]\).
  - Machine \( m_2 \) has two crossable unavailability periods respectively corresponding to intervals \([2, 2]\) and \([6, 7]\), as well as one non-crossable unavailability period corresponding to interval \([3, 3]\).
  - Machine \( m_3 \) has a single non-crossable unavailability corresponding to interval \([6, 8]\).
  - Machine \( m_4 \) has a single crossable unavailability period corresponding to interval \([3, 4]\).

- Five tasks, numbered from 1 to 5, where:
  - Task \( t_1 \) is a non-resumable task that has a virtual duration of 3.
  - Task \( t_2 \) is a resumable task that has a virtual duration of 2.
  - Task \( t_3 \) is a non-resumable task that has a virtual duration of 3.
  - Task \( t_4 \) is a resumable task that has a virtual duration of 5.
  - Task \( t_5 \) is a resumable task that has a virtual duration of 2.

- Finally, (1) all five tasks should not overlap, (2) task \( t_3 \) should precedes task \( t_2 \) and (3) task \( t_1 \) should precedes task \( t_5 \).

A survey on machine scheduling problems with unavailability constraints both in the deterministic and stochastic cases can be found in [377]. Unavailability can have multiple causes such as:

- In the context of production scheduling, machine unavailability corresponds to accepted orders that were already scheduled for a given date. This can typically corresponds to unavailability periods at the beginning of the planning horizon. Preemptive maintenance can also be another cause of machine unavailability.

- In the context of timetabling, unavailability periods may come from work regulation which enforces not to work in a continuous way more than a given limit. Unavailability periods may also come from scheduled meetings during the working day.

- In the context of distributed computing where cpu time is donated for performing huge tasks, machines are typically partially available [148].
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

3.7.2 Shared table

- **CASE**, **ELEMENTS**, **ELEMENTS_SPARSE**.

A constraint for which the same table is shared by several **ELEMENT** constraints. Within the context of the **CASE** constraint, the same directed acyclic graph can be shared by several tuples of variables. This happens, for example, when the **CASE** constraint is used for encoding all the transitions of an automaton [39].

Within the context of planning, the idea of reusing the same constraint for encoding the transitions of an automaton was proposed under the name *slice encoding* by C. Pralet and G. Verfaillie in [332]. The motivation behind was to avoid to completely unfold the behaviour of the automaton (i.e., the successive triggered transitions) over the full planning horizon. From an implementation point of view, this encoding requires the possibility to reset the domains of the variables to some initial state.

---

16 Even though the original work was not presented in the context of automata, it can be partly reinterpreted as the encoding of an automaton.
3.7.228 **Schur number** ➔

- SUM_FREE.

Denotes that a constraint was used for solving Schur problems. Given a non-negative integer \( k \), the *Schur number* \( S(k) \) is the largest integer \( n \) for which the set \( \{ 1, 2, \ldots, n \} \) can be partitioned into \( k \) sets \( S_1, S_2, \ldots, S_k \) such that \( \forall i \in [1, k] : i \in S_i \Rightarrow i + i \notin S_i \).

3.7.229 **SLAM problem** ➔

- NVECTOR.

Denotes that a constraint was used in the context of the *simultaneous localisation and map building* (SLAM) problem. Given a mobile autonomous robot that, for some reason do not has a direct way to perform self-location (for example, do not has a GPS), the problem is to dynamically build a map and locate its trajectory on that map from a set of partial snapshots of its environment. Within the context of constraint programming this problem is described in [237, 117].

3.7.230 **Sliding cyclic(1) constraint network(1)** ➔

- DECREASING,
- INCREASING,
- NO_PEAK,
- NO_VALLEY,
- NOT_ALL_EQUAL,
- STRICTLY_DECREASING,
- STRICTLY_INCREASING.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

A constraint network corresponding to the pattern depicted by Figure 3.63. Circles depict variables, while arcs are represented by a set of variables.

Figure 3.63: Hypergraph associated with a sliding cyclic(1) constraint network(1)

3.7.231 Sliding cyclic(1) constraint network(2) [20 CONS]

- ALL_EQUAL_PEAK,
- ALL_EQUAL_PEAK_MAX,
- ALL_EQUAL_VALLEY,
- ALL_EQUAL_VALLEY_MIN,

- SLIDING_TIME_WINDOW_FROM_START,
- SLIDING_TIME_WINDOW_SUM,
- STRETCH_CIRCUIT,
- STRETCH_PATH,
- STRETCH_PATH_PARTITION.

A constraint enforcing a condition on sliding sequences of domain variables that partially overlap or a constraint computing a quantity from a set of sliding sequences. These sliding sequences can be either initially given or dynamically constructed. In the latter case they can correspond, for example, to adjacent vertices of a path that has to be built.
3.7.235 Smallest square for packing consecutive dominoes

Find the smallest square \( S \) where one can place \( n \) rectangles of respective size \( 1 \times 2, 2 \times 4, \ldots, n \times 2 \cdot n \) so that they do not overlap and so that their borders are parallel to the borders of \( S \). Each rectangle can be rotated by 90 degrees. The problem is described in http://www.stetson.edu/~efriedma/dominio/. Figure 3.67 gives a solution for \( n = 22 \) found by H. Simonis.

![Figure 3.67: A solution to the smallest square for packing consecutive dominoes problem for \( n = 22 \) ]
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.236 ▶Smallest rectangle area◀

- **DIFFN**,  
- **GEOST**.

Denotes that a constraint can be used for finding the smallest rectangle area where one can pack a given set of rectangles (or squares). A first example of such packing problem attributed to S. W. Golomb is to find the smallest square that can contain the set of consecutive squares from $1 \times 1$ up to $n \times n$ so that these squares do not overlap each other. A program using the **DIFFN** constraint was used to construct such a table for $n \in \{1, 2, \ldots, 25, 27, 29, 30\}$ in [31]. New optimal solutions for this problem were found in [401] for $n = 26, 31, 35$. Figure 3.68 gives the solution found for $n = 35$ by H. Simonis and B. O’Sullivan. Algorithms and lower bounds for solving the same problem can also be respectively found in [99] and in [253].

![Figure 3.68: Smallest square (of size 123) for packing squares of size 1, 2, ..., 35](image)

In his paper (i.e., [253]), Richard E. Korf also considers the problem of finding the minimum-area rectangle that can contain the set of consecutive squares from $1 \times 1$ up to $n \times n$ and solve it up to $n = 25$. In 2008 this value was improved up to $n = 27$ by H. Simonis and B. O’Sullivan [401]. Figure 3.69 gives the solution found for $n = 27$ by H. Simonis and B. O’Sullivan.
3. DESCRIPTION OF THE CATALOGUE

3.7.237 Smallest square for packing rectangles with distinct sizes

- `DIFFN`,
- `GEOST`.

Denotes that a constraint can be used for finding the smallest square where one can pack \( n \) rectangles for which all the \( 2 \cdot n \) sizes are distinct integer values. The problem is described on [http://www.stetson.edu/~efriedma/mathmagic/0899.html](http://www.stetson.edu/~efriedma/mathmagic/0899.html). Figures 3.70, 3.71 and 3.72 present the smallest square (not necessarily optimal) found with `GEOST` for respectively placing 9, 10, 11, 12, 13 and 14 rectangles of distinct sizes.

Figure 3.69: Rectangle with the smallest surface (of size \( 148 \times 47 \)) for packing squares of size 1, 2, \ldots, 27

![Rectangle with the smallest surface](image)

Figure 3.70: (Left) Tiling a square of size 24 with 9 rectangles of distinct sizes 1 × 18, 17 × 2, 15 × 3, 4 × 14, 16 × 5, 12 × 6, 7 × 13, 10 × 8, 9 × 11; (Right) Tiling a square of size 28 with 10 rectangles of distinct sizes 1 × 20, 2 × 19, 18 × 3, 4 × 17, 5 × 16, 6 × 15, 7 × 14, 12 × 8, 9 × 13, 10 × 11.

A constraint using the SORT constraint in one of its reformulation.

3.7.241 Sparse functional dependency

- CASE,
- ELEMENT
  - Case
  - Sparse

A constraint that allows for representing a functional dependency between two domain variables, where both variables have a restricted number of values. A variable $X$ is said to functionally determine another variable $Y$ if and only if each potential value of $X$ is associated with exactly one potential value of $Y$. [3 CONS]
3. DESCRIPTION OF THE CATALOGUE

3.7.242 ◆Sparse table◆

- ELEMENT_SPARSE,
- ELEMENTS_SPARSE.

An ELEMENT constraint for which the table is sparse.

3.7.243 ◆Sport timetabling◆

- SYMMETRIC_ALLDIFFERENT,
- SYMMETRIC_ALLDIFFERENT_EXCEPT_0.

A constraint used for creating sports schedules.

3.7.244 ◆Squared squares◆

- CUMULATIVE,
- DIFFN,
- GEOST.

A constraint that can be used for modelling the squared squares problem [137] [440] (also called the perfect squared squares problem [156]): a perfect squared square of order \( n \) is a square that can be tiled with \( n \) smaller squares such that each of the smaller squares has a different integer size. It is called simple if it does not contain a subset of at least two squares, corresponding to a square or to a rectangle. Duijvestijn has shown in 1962 that no instances exist with less than 21 squares [156].

A single solution depicted by Figure 3.73 exists with 21 squares, where the squares have sizes 2, 4, 6, 7, 8, 9, 11, 15, 16, 17, 18, 19, 24, 25, 27, 29, 33, 35, 37, 42, 50 and must be packed into a square of size 112.

A catalogue of such simple squared squares of orders 21 through 25 is provided in [94]. The following table contains all the problem instances from the previous
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

catalogue. The different fields respectively give the problem number, the number of squares, the size of the master square and a list of the square sizes. Problems 166 and 167, 168 and 169, 182 and 183 are identical, but have two non-isomorphic solutions. A much bigger table can be found at the following link http://www.squaring.net/.

When the size of the squares is known four constraint programming approach are respectively reported in [1], in [427], in [398], in [42] and in [41].

3. DESCRIPTION OF THE CATALOGUE
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

373
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.245  ▼Statistics  

- DEVATION,
- SPREAD.

A constraint representing a function in statistics usually used for obtaining a balanced assignment.

3.7.246  ▼Strip packing  

- DIFFN,
- GEOST.

A constraint that can be used to model the strip packing problem: Given a set of rectangles pack them into an open ended strip of given width in order to minimise the total overall height. Borders of the rectangles to pack should be parallel to the borders of the strip and rectangles should not overlap. Some variants of strip packing allow to rotate rectangles from 90 degrees. Benchmarks with known optima can be obtained from Hopper’s PhD thesis [229].

3.7.247  ▼Strong articulation point  

- TREE.

A constraint for which the filtering algorithm uses the notion of strong articulation point. A strong articulation point of a strongly connected digraph \(G\) is a vertex such that if we remove it, \(G\) is broken into at least two strongly connected components. Figure 3.74 illustrates the notion of strong articulation point on the digraph depicted by part (A). The vertex labelled by 3 is a strong articulation point since its removal...
creates the three strongly connected components depicted by part (B) (i.e., the first, second and third strongly connected components correspond respectively to the sets of vertices \( \{1, 4\} \), \( \{2\} \) and \( \{5\} \)). From an algorithmic point of view, it was shown in [234] how to compute all the strong articulation points of a digraph \( G \) in linear time with respect to the number of arcs of \( G \).

![Figure 3.74: (A) A connected digraph, (B) its three strongly connected components](image)

Figure 3.74: (A) A connected digraph, (B) its three strongly connected components \( scc_1 \), \( scc_2 \) and \( scc_3 \) when its unique strong articulation point (i.e., the vertex labelled by 3) is removed

### 3.7.248 Strong bridge

A constraint for which the filtering algorithm may use the notion of strong bridge (i.e., enforce arcs corresponding to strong bridges to be part of the solution in order to avoid creating too many strongly connected components). A strong bridge of a strongly connected digraph \( G \) is an arc such that, if we remove it, \( G \) is broken into at least two strongly connected components. Figure 3.75 illustrates the notion of strong bridge on the digraph depicted by part (A). The arc from the vertex labelled by 2 to the vertex labelled by 1 is a strong bridge since its removal creates the three strongly connected components depicted by part (B) (i.e., the first, second and third strongly connected
components correspond respectively to the sets of vertices \{1, 3, 4\}, \{2\} and \{5\}). The other strong bridges of the digraph depicted by part (A) are the arcs \(1 \rightarrow 3\) and \(5 \rightarrow 2\). From an algorithmic point of view, it was shown in [234] how to compute all the strong bridges of a digraph \(G\) in linear time with respect to the number of arcs of \(G\).

![Figure 3.75: (A) A connected digraph, (B) its three strongly connected components \(scc_1, scc_2\) and \(scc_3\) when one of its strong bridge, the arc \(2 \rightarrow 1\), is removed](image)

3.7.249 Strongly connected component

- ATLEAST,NVALUE,
- ATLEAST,NVECTOR,
- ATMOST,NVALUE,
- ATMOST,NVECTOR,
- BALANCE,CIRCLE,
- CIRCUIT,CLUSTER,
- CONNECT,POINTS,

- NVALUE,
- NVALUES,
- NVALUES,EXCEPT,0,
- NVECTOR,
- NVECTORS,
- POLYOMINO,
- SOFT,ALLDIFFERENT,VAR,
- STRONGLY,CONNECTED,
Denotes that a constraint restricts the strongly connected components of its associated final graph. This is usually done by using a graph property like $\text{MAX}_{\text{NSCC}}$, $\text{MIN}_{\text{NSCC}}$ or $\text{NSCC}$.

3.7.250 \(\triangleright Subset\ sum \rightarrow\) [1 CONS]

- $\text{WEIGHTED\_PARTIAL\_ALLDIFF}$.

Denotes that, by reduction to subset sum, deciding whether a constraint has a solution or not was shown to be NP-hard. The subset sum problem can be described as follows: given a finite set of integers in $\mathbb{Z}^+$ and an integer $s$ in $\mathbb{Z}^+$, does any subset sum equal exactly $s$?

3.7.251 \(\triangleright Sudoku \rightarrow\) [2 CONS]

- $\text{ALLDIFFERENT}$, $\text{k\_ALLDIFFERENT}$.

A constraint that can be used for modelling the Sudoku puzzle problem. A Sudoku square is an $9 \times 9$ array in which 9 distinct numbers in $[1, 9]$ are arranged so that the following two conditions hold:

- Each number occurs once in each row and column.
- The numbers in each major $3 \times 3$ block are distinct.

The Sudoku puzzle problem is to complete a partially filled board in order to get a Sudoku square. Part (A) of Figure 3.76 gives a partially filled Sudoku board, while part (B) provides its unique possible completion.

- \textsc{Geost},
- \textsc{Geost\_time},
- \textsc{Soft\_all\_equal\_min\_var},
- \textsc{Spread},
- \textsc{Visible}.

A constraint for which the filtering algorithm may use a \textit{sweep algorithm}. A \textit{sweep algorithm} [333, pages 10–11] solves a problem by moving an imaginary object (usually...
3. DESCRIPTION OF THE CATALOGUE

a line, a plane or sometime a point). The object does not move continuously, but only at particular points where we actually do something. A sweep algorithm uses the following two data structures:

- A data structure called the **sweep status**, which contains information related to the current position of the object that moves,

- A data structure named the **event point series**, which holds the events to process.

The algorithm initialises the sweep status for the initial position of the imaginary object. Then the object jumps from one event to the next event; each event is handled by updating the status of the sweep.

A first typical application reported in [34] of the idea of sweep within the context of constraint programming is to aggregate several constraints that have two variables in common in order to perform more deduction. Let:

- **X** and **Y** be two distinct variables,

- \( C_1(V_{11}, \ldots, V_{1n_1}), \ldots, C_m(V_{m1}, \ldots, V_{mn_m}) \) be a set of \( m \) constraints such that all constraints mention **X** and **Y**.

The sweep algorithm tries to adjust the minimum value of **X** with respect to the conjunction of the previous constraints by moving a sweep-line from the minimum value of **X** to its maximum value. It accumulates within the sweep-line status the values to be currently removed from the domain of **Y**. If, for the current position \( \Delta \) of the sweep-line, all values of **Y** have to be removed, then the algorithm removes value \( \Delta \) from the domain of **X**.

A forbidden region of the constraint \( C_i \) with respect to **X** and **Y** is an ordered pair \((F^-_x , F^+_x) , (F^-_y , F^+_y)\) of intervals such that:

\[
\forall x \in [F^-_x , F^+_x], \forall y \in [F^-_y , F^+_y] : C_i(V_{i1}, \ldots, V_{in_i}) \text{ has no solution in which } X = x \text{ and } Y = y.
\]

Figure 3.77 shows five constraints and their respective forbidden regions (in pink) with respect to two given variables **X** and **Y** and their domains. The first constraint requires that **X**, **Y** and **R** be pairwise distinct. Constraints (B,C) are usual arithmetic constraints. Constraint (D) can be interpreted as requiring that two rectangles of respective origins \((X, Y)\) and \((T, U)\) and sizes \((2, 4)\) and \((3, 2)\) do not overlap. Finally, constraint (E) is a parity constraint of the sum of **X** and **Y**.

We illustrate the use of the sweep algorithm on a concrete example. Assume that we want to find out the minimum value of variable **X** with respect to the conjunction of the five constraints that were introduced by Figure 3.77, that is versus the following

---

\(^{17}\)Within the context of continuous variables, Chabert et al. [115] shows how to compute a forbidden region that contains a given unfeasible point for numerical constraints with arbitrary mathematical expressions.
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

Figure 3.77: Examples of forbidden regions (in pink) according to the two variables $X$ and $Y$ ($X \in [0, 4]$, $Y \in [0, 4]$) for five constraints.

conjunction of constraints:

\[
\begin{align*}
X &\in 0..4, Y \in 0..4, R \in 0..9, T \in 0..2, U \in 0..3 \\
\text{ALLDIFFERENT}(X, Y, R) &\quad (A) \\
|X - Y| &> 2 &\quad (B) \\
X + 2Y - 1 &< S &\quad (C) \\
X + 1 &< T \lor T + 2 &< X \lor Y + 3 &< U \lor U + 1 &< Y &\quad (D) \\
(X + Y) \mod 2 &\neq 0 &\quad (E)
\end{align*}
\]

Figure 3.78 shows the content of the sweep-line status (i.e., the forbidden values for $Y$ according the current position of the sweep-line) for different positions of the sweep-line. More precisely, the sweep-line status can be viewed as an array (see the rightmost part of Figure 3.78) which records for each possible value of $Y$ the number of forbidden regions that currently intersect the sweep-line (see the leftmost part of Figure 3.78 where these forbidden regions are coloured in red). The smallest possible value of $X$ is 4, since this is the first position of the sweep-line where the sweep-line status contains a value of $Y$ which is not forbidden (i.e., $X = 4, Y = 0$ is not covered by any forbidden region).

A second similar application of the idea of sweep in the context of the *cardinality operator* [430], where all constraints have at least two variables in common, is reported in [33]. As before, each constraint $C$ of the cardinality operator is defined by its forbidden regions with respect to a pair of variables $(X, Y)$ that occur in every constraint. In addition to that, a constraint $C$ is also defined by its *safe regions*, where a safe region
### Description of the Catalogue

#### Constraints (pink and red cells depict an infeasible pair for \((X, Y)\))

</tr>
</tbody>
</table>

#### Sweep-line Status

- \(X = 0\) values of \(Y\)
- \(X = 1\) values of \(Y\)
- \(X = 2\) values of \(Y\)
- \(X = 3\) values of \(Y\)
- \(X = 4\) values of \(Y\)

![Figure 3.78: Sweep-line status while sweeping through the potential values of variable \(X\) (i.e., values from 0 to 4) until a potentially feasible point \(X = 4, Y = 4\) wrt the five constraints (A), (B), (C), (D) and (E) is found; the sweep-line status (i.e., the rightmost column) records for a potential value \(v\) of variable \(X\) and for each potential value \(w\) of variable \(Y\) how many constraints are violated when both \(X = v\) and \(Y = w\).](image)

is the set of assignments to the pair \((X, Y)\) located in a rectangle such that the constraint always holds, no matter which values are taken by the other variables of \(C\). Then the extended sweep algorithm filters the pair of variables \((X, Y)\) right from the beginning according to the minimum and maximum number of constraints of the cardinality operator that have to hold.

A third typical application reported in [42] and in [107] of the idea of sweep within the context of multi-dimensional placement problems (for example, the DIFFN and the GEOST constraints) for filtering each coordinate of the origin of an object \(o\) to place is as follows. To adjust the minimum (respectively maximum) value of a coordinate of the origin we perform a recursive traversal of the placement space in increasing (respectively decreasing) lexicographic order and skips infeasible points that are lo-
cated in a multi-dimensional forbidden set. Each multi-dimensional forbidden set is computed from a constraint where object \( o \) occurs (for example, a non-overlapping constraint in the context of the DIFFN and the GEOST constraints). Figure 3.80 illustrates the \( k \)-dimensional lexicographic sweep algorithm in the context of \( k = 2 \) and of five non-overlapping rectangles \( r_i \) \( (i \in [1, 5]) \) of respective sizes \( (w_i, h_i) \) where \( w_1 = 2, h_1 = 1, w_2 = 3, h_2 = 1, w_3 = 1, h_3 = 1, w_4 = 1, h_4 = 3, w_5 = 5, h_5 = 4 \). For each rectangle \( r_i \) we consider the coordinates of its lower leftmost corner with abscissa \( x_i \) and ordinate \( y_i \), such that \( x_1 \in [1, 4], y_1 \in [2, 4], x_2 = 4, y_2 = 6, x_3 \in [2, 4], y_3 \in [8, 9], x_4 = 7, y_4 = 1, x_5 \in [1, 8] \) and \( y_5 \in [1, 6] \cup [8, 8] \). We focus on the filtering of the minimum value of the abscissa of rectangle \( r_5 \) (i.e., variable \( x_5 \)).

- Since rectangle \( r_5 \) should not overlap rectangles \( r_1, r_2, r_3 \) and \( r_4 \) we can compute for each non-overlapping constraint a set of forbidden points for the origin of \( r_5 \). Given two non-overlapping rectangles \( r_i \) and \( r_j \) of respective origins \( (x_i, y_i) \) and \( (x_j, y_j) \) and of respective sizes \( (w_i, h_i) \) and \( (w_j, h_j) \), there is one non-empty forbidden region for the origin of \( r_i \) of the form \([x_j - w_i + 1, x_j + w_j - 1], [y_j - h_i + 1, y_j + h_j - 1]) \) when both \( x_j - w_i + 1 \leq x_j + w_j - 1 \) and \( y_j - h_i + 1 \leq y_j + h_j - 1 \) hold, and no forbidden region otherwise \([34]\). Figure 3.79 illustrates the four possible cases leading to a non-empty forbidden region.

- Since \( r_5 \) should not overlap \( r_1 \) the points of the forbidden region \([4 - 5 + 1, 1, 1 + 2 - 1], [4 - 4 + 1, 2 + 1 - 1]) \), i.e. \(([0, 2], [1, 2]) \), are forbidden for the origin of \( r_5 \).

- Since \( r_5 \) should not overlap \( r_2 \) the points of the forbidden region \([4 - 5 + 1, 4 + 3 - 1], [6 - 4 + 1, 6 + 1 - 1]) \), i.e. \(([0, 6], [3, 6]) \), are forbidden for the origin of \( r_5 \).

- Since \( r_5 \) should not overlap \( r_3 \) the points of the forbidden region \([4 - 5 + 1, 2 + 1 - 1], [9 - 4 + 1, 8 + 1 - 1]) \), i.e. \(([0, 2], [6, 8]) \), are forbidden for the origin of \( r_5 \).

- Since \( r_5 \) should not overlap \( r_4 \) the points of the forbidden region \([7 - 5 + 1, 7 + 1 - 1], [1 - 4 + 1, 3 + 1 - 3]) \), i.e. \(([3, 7], [-2, 3]) \), are forbidden for the origin of \( r_5 \).

Since \( y_5 \neq 7 \) the points of the forbidden region \([1, 8], [7, 7]) \) are also forbidden for the origin of \( r_5 \).

- In Part (A) we represent the extreme positions of rectangles \( r_1 \) to \( r_4 \); for example, the leftmost lower corner of rectangle \( r_1 \) can only be fixed at positions \((1, 2), (1, 3), (1, 4), (2, 2), (2, 3), (2, 4), (3, 2), (3, 3), (3, 4), (4, 2), (4, 3) \) and \((4, 4)\) from which positions \((1, 2), (1, 4), (4, 2) \) and \((4, 4)\) are the extreme positions. Since we prune the absicssa of the coordinate of the origin of \( r_5 \) the absicssa and ordinate dimensions of the placement space correspond respectively to the outer and to the inner dimensions of the placement space: the sweep-point first moves along the inner dimension before jumping on the outer dimension.

- Part (B) represents the first step of the sweep-point algorithm. We start the traversal of the placement space at the extreme point \( c = (1, 1) \), i.e. the extreme
leftmost lower coordinate of the origin of rectangle $r_5$. Since the sweep-point belongs to the forbidden region associated with the non-overlapping constraint between $r_5$ and $r_1$, i.e. the red box with the dash border, we compute the first point outside the forbidden region along the inner sweep dimension. As a consequence, the sweep-point moves to the next position $(1, 3)$.

- The process is repeated in Parts (C) to (H) until we finally find a position for the sweep-point that does not belong to any forbidden region derived from the constraints where rectangle $r_5$ is involved (i.e., point $(3, 8)$ in Part (I)).
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

Figure 3.79: Given two rectangles $r_1$ and $r_2$ that should not overlap, interpretation of a non-empty forbidden region for the origin of $r_1$ wrt $r_2$: four cases (A), (B), (C) and (D) depending of the size of $r_2$ versus the size of placement domain of $r_2$; a point belongs to the forbidden region if and only if all compulsory parts of $r_2$ are intersected by $r_1$ (i.e., since all points of the compulsory part are occupied) and if all frontier parts of $r_2$ are completely covered by $r_1$ (i.e., since at least one point of the frontier part is occupied).
Figure 3.80: Illustration of the sweep point algorithm for adjusting the minimum value of the abscissa of rectangle $r_5$ (within the placement space, the grey area represents forbidden placement for the origin of $r_5$ due to the domain of $y_5$)
3.7. **KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS**

The worst case complexity of the $k$-dimensional lexicographic sweep algorithm depends on the maximum number of jumps of the sweep point. Figure 3.81 shows for $k = 2$ an example where the number of jumps turns out to be proportional to $n^2$ where $n$ is the number of forbidden regions. We conjecture that we get a similar scheme, i.e. $O(n^k)$ maximum number of jumps, as $k$ increases. However from a practical point of view, experiments have shown that we dont get such bad behavior for small values of $k$, i.e. up to $k = 7$, which turns out to be enough for many packing problems.

Figure 3.81: Illustration of a configuration in two dimensions leading to a quadratic number of jumps of the sweep-point: (A) the goal is to filter the minimum value abscissa of the origin of the cyan square so that it does not overlap all the seven pink rectangles; (B), (C), (D), (E) first, second, third and fourth steps for saturating the inner sweep dimension, (F) first feasible position of the sweep point of coordinates $(5, 1)$ in blue; note that the forbidden regions for the origin of the cyan square correspond exactly to the fixed pink rectangles since the cyan square has a size of 1.
3. DESCRIPTION OF THE CATALOGUE

3.7.254 Symmetric

- ALL_DIFFER_FROM_AT_LEAST_K_POS
- ALL_DIFFER_FROM_AT_MOST_K_POS
- ALL_DIFFER_FROM_EXACTLY_K_POS
- ALL_INCOMPARABLE
- BIPARTITE
- CLIQUE
- CONNECT_POINTS
- CONNECTED
- INVERSE_WITHIN_RANGE
- PROPER_FOREST
- SYMMETRIC

Denotes that a constraint is defined by a graph constraint for which the final graph is symmetric. A digraph is symmetric if and only if, if there is an arc from a vertex \( u \) to a vertex \( v \), there is also an arc from \( v \) to \( u \).

3.7.255 Symmetry

- ALLPERM
- INCREASING_GLOBAL_CARDINALITY
- INCREASING_NVALUE
- INCREASING_SUM
- INT_VALUE_PRECEDE
- INT_VALUE_PRECEDE_CHAIN
- GEOST
- LEX2
- LEX_BETWEEN
- LEX_CHAIN_GREATER
- LEX_CHAIN_GREATEREQ
- LEX_CHAIN_LESS
- LEX_CHAIN_LESSEQ
- LEX_GREATER
- LEX_GREATEREQ

- SYMMETRIC_ALLDIFFERENT_EXCEPT_0,  
- SYMMETRIC_CARDINALITY,  
- SYMMETRIC_GCC,  
- TRACK.

A constraint that can occur in timetabling problems.
3. DESCRIPTION OF THE CATALOGUE

3.7.261 Time window

- SLIDING_TIME_WINDOW_SUM.

A constraint involving one or several date ranges.

3.7.262 Touch

- ORTHS_ARE_CONNECTED,
- TWO_ORTH_ARE_IN_CONTACT.

A constraint enforcing that some orthotopes touch each other (see Contact).

3.7.263 Tree

- BALANCE_PATH,
- BALANCE_TREE,
- BINARY_TREE,
- PATH,
- PROPER_FOREST,
- STABLE_COMPATIBILITY,
- TREE,
- TREE_RANGE,
- TREE_RESOURCE.

According to the context, the keyword tree has the following meaning:

- In the context of a digraph, a constraint that partitions the vertices of a given initial digraph and that keeps a single successor for each vertex so that each partition corresponds to one tree. Each vertex points to its father or to itself if it corresponds to the root of a tree.
• In the context of an *undirected graph* a constraint that partitions the vertices of a given initial undirected graph in a set of connected components with no cycles.

### 3.7.264 Tuple

A constraint involving a *tuple*. A *tuple* is an element of a *relation*, where a *relation* is a subset of the product of several finite sets.

### 3.7.265 Two-dimensional orthogonal packing

A constraint that can be used to model the *two-dimensional orthogonal packing problem*. Given a set of rectangles pack them into a rectangular placement space. Borders of the rectangles should be parallel to the borders of the placement space and rectangles should not overlap. Some variants of strip packing allow to rotate rectangles from 90 degrees. Benchmarks can be obtained from a generator described in the following paper [126].
3. DESCRIPTION OF THE CATALOGUE

3.7.266 Unary constraint ➔

- IN,
- IN_INTERVAL,
- IN_INTERVALS,
- NOT_IN,
- SUM_FREE.

A constraint involving only one variable.

3.7.267 Undirected graph ➔

- PROPER_FOREST,
- TOUR.

A constraint that deals with an undirected graph. An undirected graph is a graph whose edges consist of unordered pairs of vertices.

3.7.268 Value constraint ➔

- SOFT_ALL_EQUAL_MAX_VAR,
- SOFT_ALL_EQUAL_MIN_CTR,
- SOFT_ALL_EQUAL_MIN_VAR,
- SOME_EQUAL,
- VEC_EQ_TUPLE.

A constraint that puts a restriction on how values can be assigned to usually one or several collections of variables, or possibly one or two variables. These variables usually correspond to domain variables but can sometimes be set variables.
3. DESCRIPTION OF THE CATALOGUE

3.7.269  ▼Value partitioning constraint ➔

- ATLEAST_NVALUE,
- ATLEAST_NVECTOR,
- ATMOST_NVALUE,
- ATMOST_NVECTOR,
- INCREASING_NVALUE,
- NCLASS,
- NEQUIVALENCE,
- NINTERVAL,
- NPAIR,
- NVALUE,
- NVALUES,
- NVALUES_EXCEPT_0,
- NVECTOR,
- NVECTORS.

A constraint involving a partitioning of values in its definition.

3.7.270  ▼Value precedence ➔

- INT_VALUE_PRECEDE,
- INT_VALUE_PRECEDE_CHAIN,
- SET_VALUE_PRECEDE.

A constraint that allows for expressing symmetries between values that are assigned to variables: given a solution, values can be uniformly interchanged in order to obtain a new solution. This is the case, for example, in graph colouring problems or in bin-packing problems when all bins are identical (e.g., see the BIN_PACKING constraint):

- For graph coloring problems, a variable and a value correspond respectively to a vertex, and to a colour used for coloring a vertex.

- For bin packing problems, a variable and a value correspond respectively to an item to pack, and to the bin where the item is assigned.

To break such symmetry we can order the values in such a way that the first occurrence of the $i^{th}$ value occurs before the first occurrence of the $(i + 1)^{th}$ value.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.271 ▼Variable-based violation measure ➞ [11 CONS]

Denotes that one (or more) argument of a constraint corresponds to a collection of vectors that all have the same number of components.
3.7.275 \textbf{\textsc{v}partition} \Rightarrow

- \textbf{GROUP}.

Denotes that a constraint is defined by two graph constraints $C_1$ and $C_2$ such that:
- The two graph constraints have the same initial graph $G_i$,
- Each vertex of the initial graph $G_i$ belongs to exactly one of the final graphs associated with $C_1$ and $C_2$.

3.7.276 \textbf{\textsc{v}Weighted assignment} \Rightarrow

- \textsc{GLOBAL\_CARDINALITY\_WITH\_COSTS},
- \textsc{MINIMUM\_WEIGHT\_ALLDIFFERENT},
- \textsc{SUM\_OF\_WEIGHTS\_OF\_DISTINCT\_VALUES},
- \textsc{WEIGHTED\_PARTIAL\_ALLDIFF}.

A constraint expressing an assignment problem such that a cost can be computed from each solution.

3.7.277 \textbf{\textsc{v}Workload covering} \Rightarrow

- \textsc{CUMULATIVES}.

A constraint that can be used for modelling problems where a first set of tasks $\mathcal{T}_1$ has to cover a second set of tasks $\mathcal{T}_2$. Each task of $\mathcal{T}_1$ and $\mathcal{T}_2$ is defined by an origin, a duration and a height. At each point in time $t$ the sum of the heights of the tasks of the first set $\mathcal{T}_1$ that overlap $t$ has to be greater than or equal to the sum of the heights of the tasks of the second set $\mathcal{T}_2$ that also overlap $t$. 
3.7.278  Zebra puzzle

A constraint that can be used for modelling the *zebra puzzle* problem. Here is the first known publication of that puzzle quoted in italic from Life International, December 17, 1962:

1. There are five houses.
2. The Englishman lives in the red house.
3. The Spaniard owns the dog.
4. Coffee is drunk in the green house.
5. The Ukrainian drinks tea.
6. The green house is immediately to the right of the ivory house.
7. The Old Gold smoker owns snails.
8. Kools are smoked in the yellow house.
9. Milk is drunk in the middle house.
10. The Norwegian lives in the first house.
11. The man who smokes Chesterfields lives in the house next to the man with the fox.
12. Kools are smoked in the house next to the house where the horse is kept.
13. The Lucky Strike smoker drinks orange juice.
15. The Norwegian lives next to the blue house.

Now, who drinks water? Who owns the zebra?

In the interest of clarity, it must be added that each of the five houses is painted a different colour, and their inhabitants are of different national extractions, own different pets, drink different beverages and smoke different brands of American cigarettes. In statement 6, right refers to the reader’s right.

A first model involves *ELEMENT* constraints with variables in their tables (i.e., the table of an *ELEMENT* constraint corresponds to its second argument). It consists of creating for each house *i* (1 ≤ *i* ≤ 5) five variables *C*, *N*, *A*, *D*, *B* respectively corresponding to the *colour* of house *i*, the *nationality* of the person living in house *i*, the *pet* of the person leaving in house *i*, the preferred *beverage* of the person leaving in house *i*, the preferred *brand of American cigarettes* of the person.
leaving in house \( i \). We first state the following five \textsc{alldifferent} constraints on these variables for expressing that colours, nationalities, pets, beverages, and brands of American cigarettes are distinct:

- \textsc{alldifferent}(\langle C_1, C_2, C_3, C_4, C_5 \rangle),
- \textsc{alldifferent}(\langle N_1, N_2, N_3, N_4, N_5 \rangle),
- \textsc{alldifferent}(\langle A_1, A_2, A_3, A_4, A_5 \rangle),
- \textsc{alldifferent}(\langle D_1, D_2, D_3, D_4, D_5 \rangle),
- \textsc{alldifferent}(\langle B_1, B_2, B_3, B_4, B_5 \rangle).

Now note that most statements link two specific attributes (e.g., \textit{The Englishman lives in the red house}). Consequently, in order to ease the encoding of such statements in term of constraints, we will first create for each attribute a variable that indicates the house where an attribute occurs. For example, for the statement \textit{The Englishman lives in the red house} we will create two variables which respectively indicate in which house the Englishman lives and which house is red. We now create all the variables attached to each class of attributes.

For each possible colour \( c \in \{ \text{red}, \text{green}, \text{ivory}, \text{yellow}, \text{blue} \} \) we create a variable \( I_c \) that corresponds to the index of the house having this colour. For each variable \( I_c \), an \textsc{element} constraint links it to the variables \( C_1, C_2, C_3, C_4, C_5 \) giving the colour of each house:

- \textsc{element}(\( I_{\text{red}} \), \( \langle C_1, C_2, C_3, C_4, C_5 \rangle \), \( \text{Red} \)),
- \textsc{element}(\( I_{\text{green}} \), \( \langle C_1, C_2, C_3, C_4, C_5 \rangle \), \( \text{Green} \)),
- \textsc{element}(\( I_{\text{ivory}} \), \( \langle C_1, C_2, C_3, C_4, C_5 \rangle \), \( \text{Ivory} \)),
- \textsc{element}(\( I_{\text{yellow}} \), \( \langle C_1, C_2, C_3, C_4, C_5 \rangle \), \( \text{Yellow} \)),
- \textsc{element}(\( I_{\text{blue}} \), \( \langle C_1, C_2, C_3, C_4, C_5 \rangle \), \( \text{Blue} \)).

Note that we can replace the five previous \textsc{element} constraints by the following \textsc{inverse} constraint:

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} - C_1 & \text{pred} - I_{\text{red}} \\
\text{index} - 2 & \text{succ} - C_2 & \text{pred} - I_{\text{green}} \\
\text{index} - 3 & \text{succ} - C_3 & \text{pred} - I_{\text{ivory}} \\
\text{index} - 4 & \text{succ} - C_4 & \text{pred} - I_{\text{yellow}} \\
\text{index} - 5 & \text{succ} - C_5 & \text{pred} - I_{\text{blue}}
\end{pmatrix}
\]

For each possible nationality \( n \in \{ \text{englishman}, \text{spaniard}, \text{ukrainian}, \text{norwegian}, \text{japanese} \} \) we create a variable \( I_n \) that corresponds to the index of the house where the person with this nationality lives. For each variable \( I_n \), an \textsc{element} constraint links it to the variables \( N_1, N_2, N_3, N_4, N_5 \) giving the nationality associated with each house:
3. DESCRIPTION OF THE CATALOGUE

- Englishman = 1, Spaniard = 2, Ukrainian = 3, Norwegian = 4, Japanese = 5,
- \( \text{ELEMENT}(I_{\text{englishman}}, \{N_1, N_2, N_3, N_4, N_5\}, \text{Englishman}) \),
- \( \text{ELEMENT}(I_{\text{spaniard}}, \{N_1, N_2, N_3, N_4, N_5\}, \text{Spaniard}) \),
- \( \text{ELEMENT}(I_{\text{ukrainian}}, \{N_1, N_2, N_3, N_4, N_5\}, \text{Ukrainian}) \),
- \( \text{ELEMENT}(I_{\text{norwegian}}, \{N_1, N_2, N_3, N_4, N_5\}, \text{Norwegian}) \),
- \( \text{ELEMENT}(I_{\text{japanese}}, \{N_1, N_2, N_3, N_4, N_5\}, \text{Japanese}) \).

Again we can replace the five previous \text{ELEMENT} constraints by the following \text{INVERSE} constraint:

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} - N_1 & \text{pred} - I_{\text{englishman}},
\text{index} - 2 & \text{succ} - N_2 & \text{pred} - I_{\text{spaniard}},
\text{index} - 3 & \text{succ} - N_3 & \text{pred} - I_{\text{ukrainian}},
\text{index} - 4 & \text{succ} - N_4 & \text{pred} - I_{\text{norwegian}},
\text{index} - 5 & \text{succ} - N_5 & \text{pred} - I_{\text{japanese}}.
\end{pmatrix}
\]

For each possible preferred pet \( a \in \{\text{dog}, \text{snail}, \text{fox}, \text{horse}, \text{zebra}\} \) we create a variable \( I_a \) that corresponds to the index of the house where the person that prefers this pet lives. For each variable \( I_a \), an \text{ELEMENT} constraint links it to the variables \( A_1, A_2, A_3, A_4, A_5 \) giving the preferred pet of each house:

- Dog = 1, Snail = 2, Fox = 3, Horse = 4, Zebra = 5,
- \( \text{ELEMENT}(I_{\text{dog}}, \{A_1, A_2, A_3, A_4, A_5\}, \text{Dog}) \),
- \( \text{ELEMENT}(I_{\text{snail}}, \{A_1, A_2, A_3, A_4, A_5\}, \text{Snail}) \),
- \( \text{ELEMENT}(I_{\text{fox}}, \{A_1, A_2, A_3, A_4, A_5\}, \text{Fox}) \),
- \( \text{ELEMENT}(I_{\text{horse}}, \{A_1, A_2, A_3, A_4, A_5\}, \text{Horse}) \),
- \( \text{ELEMENT}(I_{\text{zebra}}, \{A_1, A_2, A_3, A_4, A_5\}, \text{Zebra}) \).

Again we can replace the five previous \text{ELEMENT} constraints by the following \text{INVERSE} constraint:

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} - A_1 & \text{pred} - I_{\text{dog}},
\text{index} - 2 & \text{succ} - A_2 & \text{pred} - I_{\text{snail}},
\text{index} - 3 & \text{succ} - A_3 & \text{pred} - I_{\text{fox}},
\text{index} - 4 & \text{succ} - A_4 & \text{pred} - I_{\text{horse}},
\text{index} - 5 & \text{succ} - A_5 & \text{pred} - I_{\text{zebra}}.
\end{pmatrix}
\]

For each possible preferred beverage \( d \in \{\text{coffee}, \text{tea}, \text{milk}, \text{orange juice}, \text{water}\} \) we create a variable \( I_d \) that corresponds to the index of the house where the person that prefers this beverage lives. For each variable \( I_d \), an \text{ELEMENT} constraint links it to the variables \( D_1, D_2, D_3, D_4, D_5 \) giving the preferred beverage of each house:
• Coffee = 1, Tea = 2, Milk = 3, Orange_juice = 4, Water = 5.
• ELEMENT(I_{coffee}, \langle D_1, D_2, D_3, D_4, D_5 \rangle, Coffee),
• ELEMENT(I_{tea}, \langle D_1, D_2, D_3, D_4, D_5 \rangle, Tea),
• ELEMENT(I_{milk}, \langle D_1, D_2, D_3, D_4, D_5 \rangle, Milk),
• ELEMENT(I_{orange_juice}, \langle D_1, D_2, D_3, D_4, D_5 \rangle, Orange_juice),
• ELEMENT(I_{water}, \langle D_1, D_2, D_3, D_4, D_5 \rangle, Water).

Again we can replace the five previous ELEMENT constraints by the following INVERSE constraint:

\[
\begin{pmatrix}
index - 1 & \text{succ - } D_1 & \text{pred - } I_{\text{coffee}} \\
index - 2 & \text{succ - } D_2 & \text{pred - } I_{\text{tea}} \\
index - 3 & \text{succ - } D_3 & \text{pred - } I_{\text{milk}} \\
index - 4 & \text{succ - } D_4 & \text{pred - } I_{\text{orange_juice}} \\
index - 5 & \text{succ - } D_5 & \text{pred - } I_{\text{water}}
\end{pmatrix}
\]

For each possible preferred brand of American cigarettes \( b \in \{ \text{old_gold}, \text{kool}, \text{chesterfield}, \text{lucky_strike}, \text{parliament} \} \) we create a variable \( I_b \) that corresponds to the index of the house where the person that prefers this brand lives. For each variable \( I_b \), an ELEMENT constraint links it to the variables \( B_1, B_2, B_3, B_4, B_5 \) giving the preferred brand of American cigarettes of each house:

• Old_gold = 1, Kool = 2, Chesterfield = 3, Lucky_strike = 4, Parliament = 5,
• ELEMENT(I_{old_gold}, \langle B_1, B_2, B_3, B_4, B_5 \rangle, Old_gold),
• ELEMENT(I_{kool}, \langle B_1, B_2, B_3, B_4, B_5 \rangle, Kool),
• ELEMENT(I_{chesterfield}, \langle B_1, B_2, B_3, B_4, B_5 \rangle, Chesterfield),
• ELEMENT(I_{lucky_strike}, \langle B_1, B_2, B_3, B_4, B_5 \rangle, Lucky_strike),
• ELEMENT(I_{parliament}, \langle B_1, B_2, B_3, B_4, B_5 \rangle, Parliament).

Again we can replace the five previous ELEMENT constraints by the following INVERSE constraint:

\[
\begin{pmatrix}
index - 1 & \text{succ - } B_1 & \text{pred - } I_{\text{old_gold}} \\
index - 2 & \text{succ - } B_2 & \text{pred - } I_{\text{kool}} \\
index - 3 & \text{succ - } B_3 & \text{pred - } I_{\text{chesterfield}} \\
index - 4 & \text{succ - } B_4 & \text{pred - } I_{\text{lucky_strike}} \\
index - 5 & \text{succ - } B_5 & \text{pred - } I_{\text{parliament}}
\end{pmatrix}
\]

Finally we state one constraint for each statement from 2 to 15:

• \( I_{\text{englishman}} = I_{\text{red}} \) (the Englishman lives in the red house).
3. DESCRIPTION OF THE CATALOGUE

- $I_{\text{spaniard}} = I_{\text{dog}}$ (the Spaniard owns the dog).
- $I_{\text{coffee}} = I_{\text{green}}$ (coffee is drunk in the green house).
- $I_{\text{ukrainian}} = I_{\text{tea}}$ (the Ukrainian drinks tea).
- $I_{\text{green}} = I_{\text{ivory}} + 1$ (the green house is immediately to the right of the ivory house).
- $I_{\text{old, gold}} = I_{\text{snail}}$ (the Old Gold smoker owns snails).
- $I_{\text{kool}} = I_{\text{yellow}}$ (kools are smoked in the yellow house).
- $I_{\text{milk}} = 3$ (milk is drunk in the middle house).
- $I_{\text{norwegian}} = 1$ (the Norwegian lives in the first house).
- $|I_{\text{chesterfield}} - I_{\text{fox}}| = 1$ (the man who smokes Chesterfields lives in the house next to the man with the fox).
- $|I_{\text{kool}} - I_{\text{horse}}| = 1$ (kools are smoked in the house next to the house where the horse is kept).
- $I_{\text{lucky strike}} = I_{\text{orange juice}}$ (the Lucky Strike smoker drinks orange juice).
- $I_{\text{japanese}} = I_{\text{parliament}}$ (the Japanese smokes Parliaments).
- $|I_{\text{norwegian}} - I_{\text{blue}}| = 1$ (the Norwegian lives next to the blue house).

Now note that variables $C_i$, $N_i$, $A_i$, $D_i$, $B_i$ $(1 \leq i \leq 5)$ do not occur at all within the constraints encoding statements 2 to 15. Consequently they can be removed, as long as we replace the five $\text{ALLDIFFERENT}$ constraints on these variables by the following $\text{ALLDIFFERENT}$ constraints:

- $\text{ALLDIFFERENT}(\langle I_{\text{red}}, I_{\text{green}}, I_{\text{ivory}}, I_{\text{yellow}}, I_{\text{blue}} \rangle)$,
- $\text{ALLDIFFERENT}(\langle I_{\text{englishman}}, I_{\text{spaniard}}, I_{\text{ukrainian}}, I_{\text{norwegian}}, I_{\text{japanese}} \rangle)$,
- $\text{ALLDIFFERENT}(\langle I_{\text{dog}}, I_{\text{snail}}, I_{\text{fox}}, I_{\text{horse}}, I_{\text{zebra}} \rangle)$,
- $\text{ALLDIFFERENT}(\langle I_{\text{coffee}}, I_{\text{tea}}, I_{\text{milk}}, I_{\text{orange juice}}, I_{\text{water}} \rangle)$,
- $\text{ALLDIFFERENT}(\langle I_{\text{old, gold}}, I_{\text{kool}}, I_{\text{chesterfield}}, I_{\text{lucky strike}}, I_{\text{parliament}} \rangle)$.

In our experience, when confronted for the first time to this puzzle, a lot of people come up with the model that associates to each house $i$ $(1 \leq i \leq 5)$ five variables $C_i$, $N_i$, $A_i$, $D_i$, $B_i$ that describe the attributes of the person living in house $i$. However it is difficult to directly express the constraints according to these variables and the second model which associates to each attribute a variable that gives the corresponding house is more convenient for expressing the constraints.
3.7. KEYWORDS ATTACHED TO THE GLOBAL CONSTRAINTS

3.7.279 ▶ Zero-duration task

A resource scheduling constraint that accepts tasks which can potentially have a duration equal to zero. Zero-duration tasks can be used for modelling over-constrained resource scheduling problems where, due to some resource limitations, some tasks have to be discarded. This can be expressed by creating for each task $i$ a duration variable $D_i$ with values 0 and $d_i$ in its initial domain, where $d_i$ is the effective duration of task $i$ when it is not discarded. Then, depending on the relaxation cost $C_i$ associated with the fact that task $i$ is not considered, a reified constraint of the form $D_i = 0 \iff C_i = \alpha_i$ ($\alpha_i > 0$) is created. The initial domain of the cost variable $C_i$ is set to 0 and $\alpha_i$, where $\alpha_i$ is the cost associated with the decision of discarding task $i$. Then all the relaxation costs associated with the different tasks have to be aggregated together, i.e., typically by taking the sum or the maximum of the relaxation costs of the different tasks. On the one hand, the overall advantage of the approach is that it does not require developing any specific algorithm. On the other hand, the disadvantage is the lack of bounds on the overall relaxation cost that can sometimes be compensated by a specific enumeration heuristic.

4.1 Differences from the 2000 report

This section summarises the main differences with the SICS report [27] as well as of the corresponding article [28]. The main differences are listed below:

- We have both simplified and extended the way to generate the vertices of the initial graph and we have introduced a new way of defining set of vertices. We have also removed the CLIQUE(MAX) set of vertices generator since it cannot in general be evaluated in polynomial time. Therefore, we have modified the description of the constraints ASSIGN_AND_COUNTS, ASSIGN_AND_NVALUES, INTERVAL_AND_COUNT, INTERVAL_AND_SUM, BIN_PACKING, CUMULATIVE, CUMULATIVES, COLOURED_CUMULATIVE, COLOURED_CUMULATIVES, CUMULATIVE_TWO_D, which all used this feature.

- We have introduced the new arc generators PATH_1 and PATH_N, which allow for specifying an n-ary constraint for which n is not fixed. The SIZE_MAX_STARTING_SEQ_ALLDIFFERENT and the SIZE_MAX_SEQ_ALLDIFFERENT are examples of global constraints that use these arc generators in order to generate a set of sliding ALLDIFFERENT constraints.

- In addition to traditional domain variables we have introduced float, set and multiset variables as well as several global constraints mentioning float and set variables (for example, the CHOQUET [231] and the ALLDIFFERENT_BETWEEN_SETS constraints). This decision was initially motivated by the fact that several constraint systems and articles mention global constraints dealing with these types of variables. Later on, we realised that set variables also greatly simplify the interface of existing global constraints. This was especially true for those global constraints that explicitly deal with a graph, like CLIQUE or CUTSET. In this context, using a set variable for catching the successors of a vertex is quite natural. This is especially true when a vertex of the final graph can have more than one successor since it allows for avoiding a lot of 0-1 variables.
4.1. DIFFERENCES FROM THE 2000 REPORT

- We have introduced the possibility of using more than one graph constraint for defining a given global constraint (for example, the CUMULATIVE or the SORT constraints). Therefore we have removed the notion of dual graph, which was initially introduced in the original report. In this context, we now use two graph constraints, for example, CHANGE_CONTINUITY.

- On the one hand, we have introduced the following new graph parameters:
  - MAX_DRG,
  - MAX_OD,
  - MIN_DRG,
  - MIN_ID,
  - MIN_OD,
  - NTREE,
  - PATH_FROM_TO,
  - PROD,
  - RANGE,
  - RANGE_DRG,
  - RANGE_NCC,
  - SUM,
  - SUM_WEIGHT_ARC.

On the other hand, we have removed the following graph parameters:

  - NCC(COMP, val),
  - NSCC(COMP, val),
  - NTREE(ATTR, COMP, val),
  - NSOURCE_EQ_NSINK,
  - NSOURCE_GREATEREQ_NSINK.

Finally, MAX_IN_DEGREE has been renamed MAX_ID.

- We have introduced an iterator over the items of a collection in order to specify in a generic way a set of similar elementary constraints or a set of similar graph properties. This was required for describing some global constraints such as GLOBAL_CARDINALITY, CYCLE_RESOURCE or STRETCH. All these global constraints mention a condition involving some limit depending on the specific values that are actually used. For example, the GLOBAL_CARDINALITY constraint forces each value \( v \) to be respectively used at least \( \text{at least}_v \) and at most \( \text{at most}_v \) times. This iterator was also necessary in the context of graph covering constraints where one wants to cover a digraph with some patterns. Each pattern consists of one resource and several tasks. One can now attach specific constraints to the different resources. Both the CYCLE_RESOURCE and the TREE_RESOURCE constraints illustrate this point.
• We have added some standard existing global constraints that were obviously missing from the previous report. This was the case, for example, of the ELEMENT constraint.

• In order to make clear the notion of family of global constraints we have computed for each global constraint a signature, which summarises its structure. Each signature was inserted into the index so that one can retrieve all the global constraints sharing the same structure.

• We have generalised some existing global constraints. For example, the CHANGEPAIR constraint extends the CHANGE constraint. Finally we have introduced some novel global constraints like DISJOINT_TASKS or SYMMETRIC_GCC.

• We have defined the rules for specifying arc constraints.

4.2 Differences from the 2005 report

The second edition has more than 1300 pages of new content. The slots describing explicitly the meaning of a global constraint (e.g., the slots Graph model and Automaton) were moved to the last part of the description. This was motivated by the fact that most users want first to get the informal description of a global constraint (e.g., the slots Purpose and Example). Effort was not only devoted to the introduction of new constraints but also to a better description of multiple aspects like:

• The slot Symmetries describes a set of mapping that preserve the solution to a constraint (see Section 2.2.5).

• The slot Reformulation provides reformulation of a global constraint as a conjunction of constraints (see Section 2.5).

• The slot Systems gives links to concrete constraint systems.

• The slots See also and Keywords were redesigned in order to respectively indicate why we point to a given constraint (see Section 2.6) and to group together keywords by meta-keywords (see Section 3.6).

• In addition to the slots Graph model and Automaton that respectively describe the meaning of a global constraint in terms of graph properties and automaton, we have introduced the slot Logic in order to describe some geometrical constraints with first order formulae (see keyword Logic).

• Finally, an evaluator was provided for most global constraints.
4.3 Graph invariants

Within the scope of the graph-based description this section shows how to use implied constraints, which are systematically linked to the description of a global constraint. This usually occurs in the following context:

- Quite often, it happens that one wants to enforce the final graph to satisfy more than one graph property. In this context, these graph properties involve several graph parameters that cannot vary independently.

**EXAMPLE:** As a practical example, consider the GROUP constraint and its first graph constraint. It involves the four graph parameters \( \text{NCC, MIN}_\text{NCC, MAX}_\text{NCC} \) and \( \text{NVERTEX} \), which respectively correspond to the number of connected components, the number of vertices of the smallest connected component, the number of vertices of the largest connected component and the number of vertices of the final graph. In this example the number of connected components of the final graph cannot vary independently from the size of the smallest connected component. The same remark applies also for the size of the largest connected component. Having a graph invariant that directly relates the four graph parameters can dramatically improve the propagation.

- Even though the description of a global constraint involves a single graph parameter \( C \), we can introduce the number of vertices, \( \text{NVERTEX} \), and the number of arcs, \( \text{NARC} \), of the final digraph. In this context, we can take advantage of graph invariants linking \( C \), \( \text{NARC} \) and \( \text{NVERTEX} \).

- It also happens that we enforce two graph constraints \( \mathcal{GC}_1 \) and \( \mathcal{GC}_2 \) that have the same initial graph \( G \). In this context we consider the following situations:
  - Each arc of \( G \) belongs to one of the final graphs associated with \( \mathcal{GC}_1 \) or with \( \mathcal{GC}_2 \) (but not to both). An example of such global constraint is the CHANGE CONTINUITY constraint. Within the graph invariants this situation is denoted by \text{apartition}.
  - Each vertex of \( G \) belongs to one of the final graphs associated with \( \mathcal{GC}_1 \) or with \( \mathcal{GC}_2 \) (but not to both). An example of such global constraint is the GROUP constraint. Within the graph invariants this situation is denoted by \text{vpartition}.

In these situations the graph properties associated with the two graph constraints are also not independent.

In practice the graphs associated with global constraints have a regular structure that comes from the initial graph or from the property of the arc constraints. So, in addition to graph invariants that hold for any graph, we want also tighter graph invariants that hold for specific graph classes. The next section introduces the graph classes we consider, while the two other sections give the graph invariants on one and two graphs.

4.3.1 Graph classes

By definition, a graph invariant has to hold for any digraph. For example, we have the graph invariant \( \text{NARC} \leq \text{NVERTEX}^2 \), which relates the number of arcs
4. FURTHER TOPICS

and the number of vertices of any digraph. This invariant is sharp since the equality is reached for a clique. However, by considering the structure of a digraph, we can get sharper invariants. For example, if our digraph is a subset of an elementary path (e.g., we use the \textit{PATH} arc generator depicted by Figure 2.8) we have that \( \text{NARC} \leq \text{NVERTEX} - 1 \), which is a tighter bound of the maximum number of arcs since \( \text{NVERTEX} - 1 < \text{NVERTEX}^2 \). For this reason, we consider recurring graph classes that show up for different global constraints of the catalogue. Beside the graph classes that were introduced in Section 2.3.2 we also have the following classes relating several graph constraints:

- \textit{apartition}: constraint defined by two graph constraints having the same initial graph, where each arc of the initial graph belongs to one of the final graphs (but not to both).

- \textit{vpartition}: constraint defined by two graph constraints having the same initial graph, where each vertex of the initial graph belongs to one of the final graphs (but not to both).

In addition, we also consider graph constraints such that their final graphs is a subset of the graph generated by the arc generators:

- \textit{CHAIN},
- \textit{CIRCUIT},
- \textit{CLIQUE},
- \textit{CLIQUE}(\text{Comparison})
- \textit{GRID},
- \textit{LOOP},
- \textit{PATH},
- \textit{PRODUCT},
- \textit{PRODUCT}(\text{Comparison}),
- \textit{SYMMETRIC\_PRODUCT},
- \textit{SYMMETRIC\_PRODUCT}(\text{Comparison}),

where \text{Comparison} is one of the following comparison operators \( \leq, \geq, <, >, =, \neq \).

4.3.2 Format of an invariant

As we previously saw, we have graph invariants that hold for any digraph as well as tighter graph invariants for specific graph classes. As a consequence, we partition the database in groups of graph invariants. A \textit{group of graph invariants} corresponds to several invariants such that all invariants relate the same subset of graph parameters and such that all invariants are variations of the first invariant of the group taking into accounts the graph class. Therefore, the first invariant of a group has no precondition, while all other invariants have a non-empty precondition that characterises the graph class for which they hold.
4.3. GRAPH INVARIANTS

EXAMPLE: As a first example consider the group of invariants denoted by Proposition 68, which relate the number of arcs $N_{ARC}$ with the number of vertices of the smallest and largest connected component (i.e., $MIN_{NCC}$ and $MAX_{NCC}$).

$$MIN_{NCC} \neq MAX_{NCC} \Rightarrow N_{ARC} \geq MIN_{NCC} + MAX_{NCC} - 2 + (MIN_{NCC} = 1)$$

equivalence: $MIN_{NCC} \neq MAX_{NCC} \Rightarrow N_{ARC} \geq MIN_{NCC}^2 + MAX_{NCC}^2$

On the one hand, since the first rule has no precondition it corresponds to a general graph invariant. On the other hand the second rule specifies a tighter condition (since $MIN_{NCC}^2 + MAX_{NCC}^2$ is greater than or equal to $MIN_{NCC} + MAX_{NCC} - 2 + (MIN_{NCC} = 1)$), which only holds for a final graph that is reflexive, symmetric and transitive.

EXAMPLE: As a second example, consider the following group of invariants corresponding to Proposition 51, which relate the number of arcs $N_{ARC}$ to the number of vertices $N_{VERTEX}$ according to the arc generator (see Figure 2.8) used for generating the initial digraph:

$$N_{ARC} \leq N_{VERTEX}^2$$

arc gen = $CIRCUIT$: $N_{ARC} \leq N_{VERTEX}$
arc gen = $CHAIN$: $N_{ARC} \leq 2 \cdot N_{VERTEX} - 2$

arc gen = $CLIQUE(\leq)$: $N_{ARC} \leq \frac{N_{VERTEX} \cdot (N_{VERTEX} + 1)}{2}$
arc gen = $CLIQUE(\geq)$: $N_{ARC} \leq \frac{N_{VERTEX} \cdot (N_{VERTEX} + 1)}{2}$
arc gen = $CLIQUE(<)$: $N_{ARC} \leq \frac{N_{VERTEX} \cdot (N_{VERTEX} - 1)}{2}$
arc gen = $CLIQUE(>)$: $N_{ARC} \leq \frac{N_{VERTEX} \cdot (N_{VERTEX} - 1)}{2}$
arc gen = $CLIQUE(\neq)$: $N_{ARC} \leq N_{VERTEX}^2 - N_{VERTEX}$
arc gen = $CYCLE$: $N_{ARC} \leq 2 \cdot N_{VERTEX}$
arc gen = $PATH$: $N_{ARC} \leq N_{VERTEX} - 1$

4.3.3 Using the database of invariants

The purpose of this section is to provide a set of graph invariants, each invariant relating a given set of graph parameters. Once we have these graph invariants we can use them systematically by applying the following steps:

- For a given graph constraint we extract all the graph parameters occurring in its description. This can be done automatically by scanning the corresponding graph properties. Let $GP$ denote this subset of graph parameters. For each graph parameter $gp$ of $GP$ we check if we have a graph property of the form $gp = var$ where $var$ is a domain variable. If this is the case we record the pair $(gp, var)$; if not, we create a new domain variable $var$ and also record the pair $(gp, var)$.

- We then search for all groups of graph invariants involving a subset of the previous graph parameters $GP$. For each selected group we filter out those graph invariants for which the preconditions are not compatible with the graph class
of the graph constraint under consideration. In each group we finally keep those invariants that have the maximum number of preconditions (i.e., the most specialised graph invariants).

- Finally we state all the previous collected graph invariants as implied constraints. This is achieved by using the variables associated with each graph parameter.

**EXAMPLE:** We continue with the example of the GROUP constraint and its first graph constraint. The steps for creating the implied constraints are:

- We first extract the graph parameters NCC, MIN_NCC, MAX_NCC and NVERTEX from the first graph constraint of the GROUP constraint. Since all the graph properties attached to the previous graph parameters have the form \( gc = var \) we extract the corresponding domain variables and get the following pairs (NCC, NGROUP), (MIN_NCC, MIN_SIZE), (MAX_NCC, MAX_SIZE) and (NVERTEX, NVAL).

- We search for all groups of graph invariants involving the graph parameters NCC, MIN_NCC, MAX_NCC and NVERTEX and filter out the irrelevant graph invariants that cannot be applied on the graph class associated with the GROUP constraint.

- We state all the previous invariants by substituting each graph parameter by its corresponding variable, which leads to a set of implied constraints.

### 4.3.4 The database of graph invariants

For each combination of graph parameters we give the number of graph invariants we currently have. The items are sorted first in increasing number of graph parameters of the invariant, second in alphabetic order on the name of the parameters. All graph invariants assume a digraph for which each vertex has at least one arc. For some propositions, a figure depicts the corresponding final graph, that minimises or maximises a given graph parameter. The propositions of this section and their corresponding proofs use the notations introduced in Section 2.3.2 on page 68.

- **Graph invariants involving one graph parameter of a final graph:**
  - MAX_NCC: 1 (see Proposition 1),
  - MAX_NSCC: 2 (see Propositions 2 and 3),
  - MIN_NCC: 1 (see Proposition 4),
  - MIN_NSCC: 2 (see Propositions 5 and 6),
  - NARC: 1 (see Proposition 7),
  - NCC: 2 (see Propositions 8 and 9),
  - NSCC: 1 (see Proposition 10),
  - NSINK: 1 (see Proposition 11),
  - NSOURCE: 1 (see Proposition 12),
  - NVERTEX: 1 (see Proposition 13).

- **Graph invariants involving two graph parameters of a final graph:**
4.3. GRAPH INVARIANTS

- **MAX\_NCC, MAX\_NSCC**: 2 (see Propositions 14 and 15),
- **MAX\_NCC, MIN\_NCC**: 2 (see Propositions 16 and 17),
- **MAX\_NCC, NARC**: 2 (see Propositions 18 and 19),
- **MAX\_NCC, NSINK**: 2 (see Propositions 20 and 21),
- **MAX\_NCC, NSOURCE**: 2 (see Propositions 22 and 23),
- **MAX\_NCC, NVERTEX**: 2 (see Propositions 24 and 25),
- **MAX\_NSCC, MIN\_NSCC**: 2 (see Propositions 26 and 27),
- **MAX\_NSCC, NARC**: 2 (see Propositions 28 and 29),
- **MAX\_NSCC, NVERTEX**: 2 (see Propositions 30 and 31),
- **MIN\_NCC, MIN\_NSCC**: 2 (see Propositions 32 and 33),
- **MIN\_NCC, NARC**: 2 (see Propositions 34 and 35),
- **MIN\_NCC, NCC**: 1 (see Proposition 36),
- **MIN\_NCC, NVERTEX**: 3 (see Propositions 37, 38 and 39),
- **MIN\_NSCC, NARC**: 2 (see Propositions 40 and 41),
- **MIN\_NSCC, NVERTEX**: 2 (see Propositions 42 and 43),
- **NARC, NCC**: 2 (see Propositions 44 and 45),
- **NARC, NSCC**: 2 (see Propositions 46 and 47),
- **NARC, NSINK**: 1 (see Proposition 48),
- **NARC, NSOURCE**: 1 (see Proposition 49),
- **NARC, NVERTEX**: 4 (see Propositions 50, 51, 52 and 53),
- **NCC, NARC**: 2 (see Propositions 54 and 55),
- **NCC, NVERTEX**: 3 (see Propositions 56 and 57 and 58),
- **NSCC, NSINK**: 1 (see Proposition 59),
- **NSCC, NSOURCE**: 1 (see Proposition 60),
- **NSCC, NVERTEX**: 3 (see Propositions 61, 62 and 63),
- **NSINK, NVERTEX**: 2 (see Propositions 64 and 65),
- **NSOURCE, NVERTEX**: 2 (see Propositions 66 and 67).

- **Graph invariants involving three graph parameters of a final graph**:
  - **MAX\_NCC, MIN\_NCC, NARC**: 1 (see Proposition 68),
  - **MAX\_NCC, MIN\_NCC, NCC**: 1 (see Proposition 69),
  - **MAX\_NCC, MIN\_NCC, NVERTEX**: 5 (see Propositions 70, 71, 72, 73 and 74),
  - **MAX\_NCC, NARC, NCC**: 2 (see Propositions 75 and 76),
  - **MAX\_NCC, NARC, NVERTEX**: 2 (see Propositions 77 and 78),
  - **MAX\_NCC, NCC, NSINK**: 1 (see Proposition 79),
  - **MAX\_NCC, NCC, NSOURCE**: 1 (see Proposition 80),
  - **MAX\_NCC, NCC, NVERTEX**: 2 (see Propositions 81 and 82),
  - **MAX\_NSCC, MIN\_NSCC, NARC**: 1 (see Proposition 83),
  - **MAX\_NSCC, MIN\_NSCC, NSCC**: 1 (see Proposition 84),
  - **MAX\_NSCC, MIN\_NSCC, NVERTEX**: 2 (see Propositions 85 and 86),
  - **MAX\_NSCC, NCC, NVERTEX**: 1 (see Proposition 87),
  - **MAX\_NSCC, NSCC, NVERTEX**: 2 (see Propositions 88 and 89).
4. FURTHER TOPICS

- MIN, NCC, NARC, NVERTEX: 2 (see Propositions 90 and 91),
- MIN, NCC, NARC, NVERTEX: 2 (see Propositions 92 and 93),
- MIN, NSCC, NARC, NVERTEX: 1 (see Proposition 94),
- MIN, NSCC, NARC, NVERTEX: 1 (see Proposition 95),
- MIN, NSCC, NCC, NVERTEX: 2 (see Propositions 96 and 97),
- NARC, NCC, NVERTEX: 2 (see Propositions 98 and 99),
- NARC, NSCC, NVERTEX: 4 (see Propositions 100, 101, 102 and 103),
- NARC, NSCC, NCC, NVERTEX: 2 (see Propositions 104 and 105),
- NARC, NSINK, NSOURCE, NVERTEX: 2 (see Propositions 106 and 107),
- NSCC, NSINK, NSOURCE: 1 (see Proposition 108),
- NSINK, NSOURCE, NVERTEX: 1 (see Proposition 109).

• Graph invariants involving four graph parameters of a final graph:
  - MAX, MIN, NCC, NARC, NCC, NCC, NVERTEX: 2 (see Propositions 110 and 111),
  - MAX, MIN, NCC, NARC, NCC, NCC, NVERTEX: 2 (see Propositions 112 and 113),
  - MAX, MIN, NSCC, NARC, NSCC, NARC, NSCC: 2 (see Propositions 115 and 116),
  - MAX, NSCC, MIN, NSCC, NARC, NSCC, NVERTEX: 2 (see Propositions 117 and 118),
  - MIN, NCC, NARC, NCC, NCC, NVERTEX: 1 (see Proposition 119),
  - NARC, NCC, NSCC, NARC, NCC, NCC, NVERTEX: 2 (see Propositions 120 and 121),
  - NARC, NSINK, NSOURCE, NVERTEX: 1 (see Proposition 122).

• Graph invariants involving five graph parameters of a final graph:
  - MAX, MIN, NCC, NARC, NCC, NCC, NCC, NVERTEX: 1 (see Proposition 123),
  - MIN, NCC, NARC, NCC, NSCC, NVERTEX: 1 (see Proposition 124).

• Graph invariants relating two parameters of two final graphs:
  - MAX, NCC, MIN, NCC, NARC, NCC: 1 (see Proposition 125),
  - MAX, NCC, NARC, NCC, NCC: 1 (see Proposition 126),
  - NARC, NCC, NARC: 1 (see Proposition 131),
  - NCC, NCC, NCC: 2 (see Propositions 132 and 133),
  - NVERTEX, NVERTEX: 1 (see Proposition 134).

• Graph invariants relating three parameters of two final graphs:
  - MAX, NCC, MIN, NCC, NARC, NCC: 3 (see Propositions 135, 136 and 137),
  - MAX, NCC, NARC, NCC, NCC: 3 (see Propositions 138, 139 and 140),
  - MAX, NCC, MIN, NCC, NVERTEX: 1 (see Proposition 141),
  - MAX, NCC, MIN, NCC, NVERTEX: 1 (see Proposition 142),
4.3. GRAPH INVARIANTS

- $\text{MIN}_{NCC_1}, \text{NARC}_2, NCC_1$: 1 (see Proposition 143),
- $\text{MIN}_{NCC_2}, \text{NARC}_1, NCC_2$: 1 (see Proposition 144).

- **Graph invariants relating four parameters of two final graphs:**
  - $\text{MAX}_{NCC_1}, \text{MIN}_{NCC_1}, \text{MIN}_{NCC_2}, NCC_1$: 2 (see Propositions 145 and 146),
  - $\text{MAX}_{NCC_2}, \text{MIN}_{NCC_2}, \text{MIN}_{NCC_1}, NCC_2$: 2 (see Propositions 147 and 148),
  - $\text{MAX}_{NCC_1}, \text{MIN}_{NCC_1}, \text{MIN}_{NCC_2}, \text{NVERTEX}_2$: 1 (see Proposition 149),
  - $\text{MAX}_{NCC_2}, \text{MIN}_{NCC_2}, \text{MIN}_{NCC_1}, \text{NVERTEX}_1$: 1 (see Proposition 150).

- **Graph invariants relating five parameters of two final graphs:**
  - $\text{MAX}_{NCC_1}, \text{MAX}_{NCC_2}, \text{MIN}_{NCC_1}, \text{MIN}_{NCC_2}, NCC_1$: 7 (see Propositions 151, 152, 153, 154, 155, 156 and 157),
  - $\text{MAX}_{NCC_1}, \text{MAX}_{NCC_2}, \text{MIN}_{NCC_1}, \text{MIN}_{NCC_2}, \text{NCC}_2$: 7 (see Propositions 158, 159, 160, 161, 162, 163 and 164).

- **Graph invariants relating six parameters of two final graphs:**
  - $\text{MAX}_{NCC_1}, \text{MAX}_{NCC_2}, \text{MIN}_{NCC_1}, \text{MIN}_{NCC_2}, \text{NCC}_1, \text{NCC}_2$: 2 (see Propositions 165 and 166).
Graph invariants involving one parameter of a final graph

**Proposition 1.**
\[ \text{no loop} : \text{MAX}\_\text{NCC} \neq 1 \] (4.1)

*Proof.* Since we do not have any loop, a non-empty connected component has at least two vertices. \(\square\)

**Proposition 2.**
\[ \text{acyclic} : \text{MAX}\_\text{NSCC} \leq 1 \] (4.2)

*Proof.* Since we do not have any circuit, a non-empty strongly connected component consists of a single vertex. \(\square\)

**Proposition 3.**
\[ \text{no loop} : \text{MAX}\_\text{NSCC} \neq 1 \] (4.3)

*Proof.* Since we do not have any loop, a non-empty strongly connected component has at least two vertices. \(\square\)

**Proposition 4.**
\[ \text{no loop} : \text{MIN}\_\text{NCC} \neq 1 \] (4.4)

*Proof.* Since we do not have any loop, a non-empty connected component has at least two vertices. \(\square\)

**Proposition 5.**
\[ \text{acyclic} : \text{MIN}\_\text{NSCC} \leq 1 \] (4.5)

*Proof.* Since we do not have any circuit, a non-empty strongly connected component consists of a single vertex. \(\square\)

**Proposition 6.**
\[ \text{no loop} : \text{MIN}\_\text{NSCC} \neq 1 \] (4.6)

*Proof.* Since we do not have any loop, a non-empty strongly connected component has at least two vertices. \(\square\)

**Proposition 7.**
\[ \text{one succ} : \text{NARC} = \text{NVERTEX}\_\text{INITIAL} \] (4.7)

*Proof.* By definition of \text{one succ}. \(\square\)
4.3. GRAPH INVARIANTS

**Proposition 8.**

\[ \text{no loop}: 2 \cdot \text{NCC} \leq \text{NVERTEX}_{\text{INITIAL}} \]  \hspace{1cm} (4.8)

*Proof.* By definition of no loop, each connected component has at least two vertices.

**Proposition 9.**

\[ \text{consecutive loops are connected}: 2 \cdot \text{NCC} \leq \text{NVERTEX}_{\text{INITIAL}} + 1 \]  \hspace{1cm} (4.9)

*Proof.* By definition of consecutive loops are connected.

**Proposition 10.**

\[ \text{no loop}: 2 \cdot \text{NSCC} \leq \text{NVERTEX}_{\text{INITIAL}} \]  \hspace{1cm} (4.10)

*Proof.* By definition of no loop, each strongly connected component has at least two vertices.

**Proposition 11.**

\[ \text{symmetric}: \text{NSINK} = 0 \]  \hspace{1cm} (4.11)

*Proof.* Since we do not have any isolated vertex.

**Proposition 12.**

\[ \text{symmetric}: \text{NSOURCE} = 0 \]  \hspace{1cm} (4.12)

*Proof.* Since we do not have any isolated vertex.

**Proposition 13.**

\[ \text{one succ}: \text{NVERTEX} = \text{NVERTEX}_{\text{INITIAL}} \]  \hspace{1cm} (4.13)

*Proof.* By definition of one succ.
Graph invariants involving two parameters of a final graph

**Proposition 14.**
\[
\text{MAX}_N \text{CC} = 0 \iff \text{MAX}_N \text{SCC} = 0 \tag{4.14}
\]

**Proof.** By definition of \( \text{MAX}_N \text{CC} \) and of \( \text{MAX}_N \text{SCC} \).

**Proposition 15.**
\[
\text{MAX}_N \text{SCC} \leq \text{MAX}_N \text{CC} \tag{4.15}
\]

**Proof.** \( \text{MAX}_N \text{SCC} \) is a lower bound of the size of the largest connected component since the largest strongly connected component is for sure included within a connected component.

**Proposition 16.**
\[
\text{MAX}_N \text{CC} = 0 \iff \text{MIN}_N \text{CC} = 0 \tag{4.16}
\]

**Proof.** By definition of \( \text{MAX}_N \text{CC} \) and of \( \text{MIN}_N \text{CC} \).

**Proposition 17.**
\[
\text{MIN}_N \text{CC} \leq \text{MAX}_N \text{CC} \tag{4.17}
\]

**Proof.** By definition of \( \text{MIN}_N \text{CC} \) and of \( \text{MAX}_N \text{CC} \).

**Proposition 18.**
\[
\text{MAX}_N \text{CC} = 0 \iff \text{NARC} = 0 \tag{4.18}
\]

**Proof.** By definition of \( \text{MAX}_N \text{CC} \) and of \( \text{NARC} \).

**Proposition 19.**
\[
\text{MAX}_N \text{CC} > 0 \implies \text{NARC} \geq \max(1, \text{MAX}_N \text{CC} - 1) \tag{4.19}
\]

**Proof.**
(4.19) \( \text{MAX}_N \text{CC} - 1 \) arcs are needed to connect \( \text{MAX}_N \text{CC} \) vertices that belong to a given connected component containing at least two vertices. And one arc is required for a connected component containing a single vertex.

(4.20) Similarly, when the graph is symmetric, \( 2 \cdot \text{MAX}_N \text{CC} - 2 \) arcs are needed to connect \( \text{MAX}_N \text{CC} \) vertices that belong to a given connected component containing at least two vertices.

(4.21) Finally, when the graph is reflexive, symmetric and transitive, \( \text{MAX}_N \text{CC}^2 \) arcs are needed to connect \( \text{MAX}_N \text{CC} \) vertices that belong to a given connected component.

(4.22) When the initial graph corresponds to a path, the minimum number of arcs of a connected component involving \( n \) vertices is equal to \( n - 1 \).
4.3. GRAPH INVARIANTS

\[ \text{MAX\_NCC, NSINK} \]

Proposition 20.
\[ \text{MAX\_NCC} = 0 \Rightarrow \text{NSINK} = 0 \]  \hspace{1cm} (4.23)

Proof. By definition of \text{MAX\_NCC} and of \text{NSINK}.

\[ \text{MAX\_NCC, NSOURCE} \]

Proposition 21.
\[ \text{NSINK} \geq 1 \Rightarrow \text{MAX\_NCC} \geq 2 \]  \hspace{1cm} (4.24)

Proof. Since we do not have any isolated vertex a sink is connected to at least one other vertex. Therefore, if the graph has a sink, there exists at least one connected component with at least two vertices.

\[ \text{MAX\_NCC, NVERTEX} \]

Proposition 22.
\[ \text{MAX\_NCC} = 0 \Rightarrow \text{NSOURCE} = 0 \]  \hspace{1cm} (4.25)

Proof. By definition of \text{MAX\_NCC} and of \text{NSOURCE}.

Proposition 23.
\[ \text{NSOURCE} \geq 1 \Rightarrow \text{MAX\_NCC} \geq 2 \]  \hspace{1cm} (4.26)

Proof. Since we do not have any isolated vertex a source is connected to at least one other vertex. Therefore, if the graph has a source, there exists at least one connected component with at least two vertices.

\[ \text{MAX\_NSCC, MIN\_NSCC} \]

Proposition 24.
\[ \text{MAX\_NSCC} = 0 \Leftrightarrow \text{NVERTEX} = 0 \]  \hspace{1cm} (4.27)

Proof. By definition of \text{MAX\_NSCC} and of \text{NVERTEX}.

Proposition 25.
\[ \text{NVERTEX} \geq \text{MAX\_NCC} \]  \hspace{1cm} (4.28)

Proof. By definition of \text{MAX\_NCC}.

Proposition 26.
\[ \text{MAX\_NSCC} = 0 \Leftrightarrow \text{MIN\_NSCC} = 0 \]  \hspace{1cm} (4.29)

Proof. By definition of \text{MAX\_NSCC} and of \text{MIN\_NSCC}.

Proposition 27.
\[ \text{MIN\_NSCC} \leq \text{MAX\_NSCC} \]  \hspace{1cm} (4.30)

Proof. By definition of \text{MIN\_NSCC} and of \text{MAX\_NSCC}.
Proposition 28.

\[ \text{MAX\_NSCC} = 0 \iff \text{NARC} = 0 \]  

(4.31)

Proof. By definition of \text{MAX\_NSCC} and of \text{NARC}.

\[ \Box \]

Proposition 29.

\[ \text{NARC} \geq \text{MAX\_NSCC} \]  

(4.32)

symmetric: \[ \text{NARC} \geq 2 \cdot \text{MAX\_NSCC} \]  

(4.33)

equivalence: \[ \text{NARC} \geq \text{MAX\_NSCC}^2 \]  

(4.34)

Proof. (4.32) In a strongly connected component at least one arc has to leave each vertex. Since we have at least one strongly connected component of \text{MAX\_NSCC} vertices this leads to the previous inequality.

\[ \Box \]

Proposition 30.

\[ \text{MAX\_NSCC} = 0 \iff \text{NVERTEX} = 0 \]  

(4.35)

Proof. By definition of \text{MAX\_NSCC} and of \text{NVERTEX}.

\[ \Box \]

Proposition 31.

\[ \text{NVERTEX} \geq \text{MAX\_NSCC} \]  

(4.36)

Proof. By definition of \text{MAX\_NSCC}.

\[ \Box \]

Proposition 32.

\[ \text{MIN\_NCC} = 0 \iff \text{MIN\_NSCC} = 0 \]  

(4.37)

Proof. By definition of \text{MIN\_NCC} and of \text{MIN\_NSCC}.

\[ \Box \]

Proposition 33.

\[ \text{MIN\_NCC} \geq \text{MIN\_NSCC} \]  

(4.38)

Proof. By construction \text{MIN\_NCC} is an upper bound of the number of vertices of the smallest strongly connected component.

\[ \Box \]
4.3. GRAPH INVARIANTS

**Proposition 34.**

\[ \text{MIN\_NCC} = 0 \Leftrightarrow \text{NARC} = 0 \]  
(4.39)

**Proof.** By definition of \text{MIN\_NCC} and of \text{NARC}.

**Proposition 35.**

\[ \text{MIN\_NCC} > 0 \Rightarrow \text{NARC} \geq \max(1, \text{MIN\_NCC} - 1) \]  
(4.40)

 symmetric: \[ \text{MIN\_NCC} > 0 \Rightarrow \text{NARC} \geq \max(1, 2 \cdot \text{MIN\_NCC} - 2) \]  
(4.41)

equivalence: \[ \text{NARC} \geq \text{MIN\_NCC}^2 \]  
(4.42)

\[ \text{arc\_gen} = \text{PATH} : \text{NARC} \geq \text{MIN\_NCC} - 1 \]  
(4.43)

**Proof.** Similar to Proposition 19.

**Proposition 36.**

\[ \text{consecutive\_loops\_are\_connected}: (\text{MIN\_NCC} + 1) \cdot \text{NCC} \leq \text{NVERTEX\_INITIAL} + 1 \]  
(4.44)

**Proof.** By definition of \text{consecutive\_loops\_are\_connected}.

**Proposition 37.**

\[ \text{MIN\_NCC} = 0 \Leftrightarrow \text{NVERTEX} = 0 \]  
(4.45)

**Proof.** By definition of \text{MIN\_NCC} and of \text{NVERTEX}.

**Proposition 38.**

\[ \text{NVERTEX} \geq \text{MIN\_NCC} \]  
(4.46)

**Proof.** By definition of \text{MIN\_NCC}.

**Proposition 39.**

\[ \text{MIN\_NCC} \notin \left[ \min \left( \left\lfloor \frac{\text{NVERTEX}}{2} \right\rfloor, \left\lfloor \frac{\text{NVERTEX\_INITIAL} - 1}{2} \right\rfloor \right) + 1, \text{NVERTEX} - 1 \right] \]  
(4.47)

**Proof.** On the one hand, if \text{NCC} \leq 1, we have that \text{MIN\_NCC} \geq \text{NVERTEX}. On the other hand, if \text{NCC} > 1, we have that \text{MIN\_NCC} + \text{MIN\_NCC} \leq \text{NVERTEX} and that \text{MIN\_NCC} + \text{MIN\_NCC} + 1 \leq \text{NVERTEX\_INITIAL}, which by isolating \text{MIN\_NCC} and by grouping the two inequalities leads to \text{MIN\_NCC} \leq \min \left( \left\lfloor \frac{\text{NVERTEX}}{2} \right\rfloor, \left\lfloor \frac{\text{NVERTEX\_INITIAL} - 1}{2} \right\rfloor \right). The result follows.
Proposition 40.  
\[
\text{MIN\_NSCC} = 0 \iff \text{NARC} = 0 \tag{4.48}
\]

Proof. By definition of MIN\_NSCC and of NARC.

Proposition 41.  
\[
\text{NARC} \geq \text{MIN\_NSCC} \tag{4.49}
\]

symmetric: \[
\text{NARC} \geq 2 \cdot \text{MIN\_NSCC} \tag{4.50}
\]

equivalence: \[
\text{NARC} \geq \text{MIN\_NSCC}^2 \tag{4.51}
\]

Proof. Similar to Proposition 29.

Proposition 42.  
\[
\text{MIN\_NSCC} = 0 \iff \text{NVERTEX} = 0 \tag{4.52}
\]

Proof. By definition of MIN\_NSCC and of NVERTEX.

Proposition 43.  
\[
\text{NVERTEX} \geq \text{MIN\_NSCC} \tag{4.53}
\]

Proof. By definition of MIN\_NSCC.

Proposition 44.  
\[
\text{NARC} = 0 \iff \text{NCC} = 0 \tag{4.54}
\]

Proof. By definition of NARC and of NCC.

Proposition 45.  
\[
\text{NARC} \geq \text{NCC} \tag{4.55}
\]

Proof. Each connected component contains at least one arc (since, by hypothesis, each vertex has at least one arc).

Proposition 46.  
\[
\text{NARC} = 0 \iff \text{NSCC} = 0 \tag{4.56}
\]

Proof. By definition of NARC and of NSCC.

Proposition 47.  
\[
\text{NARC} \geq \text{NSCC} \tag{4.57}
\]

no loop: \[
\text{NARC} \geq 2 \cdot \text{NSCC} \tag{4.58}
\]

Proof. 4.57 (respectively 4.58) holds since each strongly connected component contains at least one (respectively two) arc(s).
4.3. GRAPH INVARIANTS

**Proposition 48.**

\[ \text{NARC} \geq \text{NSINK} \]  
(4.59)

*Proof.* Since isolated vertices are not allowed, each sink has a distinct ingoing arc. \( \square \)

**Proposition 49.**

\[ \text{NARC} \geq \text{NSOURCE} \]  
(4.60)

*Proof.* Since isolated vertices are not allowed, each source has a distinct outgoing arc. \( \square \)

**Proposition 50.**

\[ \text{NARC} = 0 \iff \text{NVERTEX} = 0 \]  
(4.61)

*Proof.* By definition of \( \text{NARC} \) and of \( \text{NVERTEX} \). \( \square \)

**Proposition 51.**

\[
\begin{align*}
\text{arc}_{\text{gen}} & = \text{CIRCUIT} : \text{NARC} \leq \text{NVERTEX}^2 \\
\text{arc}_{\text{gen}} & = \text{CHAIN} : \text{NARC} \leq 2 \cdot \text{NVERTEX} - 2 \\
\text{arc}_{\text{gen}} & = \text{CLIQUE}(\leq) : \text{NARC} \leq \frac{\text{NVERTEX} \cdot (\text{NVERTEX} + 1)}{2} \\
\text{arc}_{\text{gen}} & = \text{CLIQUE}(\geq) : \text{NARC} \leq \frac{\text{NVERTEX} \cdot (\text{NVERTEX} + 1)}{2} \\
\text{arc}_{\text{gen}} & = \text{CLIQUE}(<) : \text{NARC} \leq \frac{\text{NVERTEX} \cdot (\text{NVERTEX} - 1)}{2} \\
\text{arc}_{\text{gen}} & = \text{CLIQUE}(>) : \text{NARC} \leq \frac{\text{NVERTEX} \cdot (\text{NVERTEX} - 1)}{2} \\
\text{arc}_{\text{gen}} & = \text{CLIQUE}(\neq) : \text{NARC} \leq \text{NVERTEX}^2 - \text{NVERTEX} \\
\text{arc}_{\text{gen}} & = \text{CYCLE} : \text{NARC} \leq 2 \cdot \text{NVERTEX} \\
\text{arc}_{\text{gen}} & = \text{PATH} : \text{NARC} \leq \text{NVERTEX} - 1
\end{align*}
\]  
(4.62-4.71)

*Proof.* 4.62 holds since each vertex of a digraph can have at most \( \text{NVERTEX} \) successors. The next items correspond to the maximum number of arcs that can be achieved according to a specific arc generator. \( \square \)

Note that, when the equality is reached in 4.62, the corresponding extreme graph is in fact the graph initially generated. The same observation holds for inequalities 4.63 to 4.71. As a consequence all \( U \)-arcs have to be turned into \( T \)-arcs.

**Proposition 52.**

\[ 2 \cdot \text{NARC} \geq \text{NVERTEX} \]  
(4.72)

*Proof.* By induction on the number of vertices of a graph \( G \):

1. If \( \text{NVERTEX}(G) \) is equal to 1 or 2 Proposition 52 holds.
2. Assume that $\text{NVERTEX}(G) \geq 3$.

- Assume there exists a vertex $v$ such that, if we remove $v$, we do not create any isolated vertex in the remaining graph. We have $\text{NARC}(G) \geq \text{NARC}(G - v) + 1$. Thus $2 \cdot \text{NARC}(G) \geq 2 \cdot \text{NARC}(G - v) + 1$. Since by induction hypothesis $2 \cdot \text{NARC}(G - v) \geq \text{NVERTEX}(G - v) = \text{NVERTEX}(G) - 1$ the result holds.

- Otherwise, all the connected components of $G$ are reduced to two elements with only one arc. We remove one of such connected component $(v, w)$. Thus $\text{NARC}(G) = \text{NARC}(G - \{v, w\}) + 1$. As by induction hypothesis, $2 \cdot \text{NARC}(G - \{v, w\}) \geq \text{NVERTEX}(G - \{v, w\}) = \text{NVERTEX}(G) - 2$ the result holds.

Note that, when the equality is reached in 52, the corresponding extreme graph is in fact a perfect matching of the graph. As a consequence all $U$-arcs that do not belong to any perfect matching have to be turned into $F$-arcs.

**Proposition 53.**
\[
\text{arc-gen} = \text{LOOP} : \text{NARC} = \text{NVERTEX}
\] (4.73)

**Proof.** From the definition of $\text{LOOP}$. \qed

**Proposition 54.**
\[
\text{NCC} = 0 \iff \text{NSCC} = 0
\] (4.74)

**Proof.** By definition of $\text{NCC}$ and of $\text{NSCC}$. \qed

**Proposition 55.**
\[
\text{NCC} \leq \text{NSCC}
\] (4.75)

**Proof.** Holds since each connected component contains at least one strongly connected component. \qed

Note that, when the equality is reached in 55, each connected component of the corresponding extreme graph is strongly connected. As a consequence all sink vertices of the graph induced by the $T$-vertices and the $T$-arcs should have at least one successor.

**Proposition 56.**
\[
\text{NCC} = 0 \iff \text{NVERTEX} = 0
\] (4.76)

**Proof.** By definition of $\text{NCC}$ and of $\text{NVERTEX}$. \qed

**Proposition 57.**
\[
\text{NCC} \leq \text{NVERTEX}
\] (4.77)

\[\text{no loop} : 2 \cdot \text{NCC} \leq \text{NVERTEX}
\] (4.78)

**Proof.** 4.77 (respectively 4.78) holds since each connected component contains at least one (respectively two) vertex. \qed
4.3. **GRAPH INVARIANTS**

Note that, when the equality is reached in 4.77, the corresponding extreme graph does not contain any arc between two distinct vertices. As a consequence any $U$-arc between two distinct vertices is turned into a $F$-vertex.

**Proposition 58.**

\[
\text{\texttt{vpartition \land consecutive_loops_are_connected :}} \\
\quad \text{\texttt{NVERTEX \leq NVERTEX}}_\text{INITIAL} - (\text{NCC} - 1) \quad (4.79)
\]

**Proof.** Holds since between two “consecutive” connected components of the initial graph there is at least one vertex that is missing. \[
\]

**Proposition 59.**

\[
\text{\texttt{NSCC \geq NSINK}} + 1 \quad (4.80)
\]

**Proof.** Since each sink cannot belong to a circuit and since no isolated vertex is allowed at least one extra non-sink vertex is required the result follows. \[
\]

**Proposition 60.**

\[
\text{\texttt{NSCC \geq NSOURCE}} + 1 \quad (4.81)
\]

**Proof.** Since each source cannot belong to a circuit and since no isolated vertex is allowed at least one extra non-source vertex is required the result follows. \[
\]

**Proposition 61.**

\[
\text{\texttt{NSCC = 0 \iff NVERTEX = 0}} \quad (4.82)
\]

**Proof.** By definition of \texttt{NSCC} and of \texttt{NVERTEX}. \[
\]

**Proposition 62.**

\[
\text{\texttt{NSCC \leq NVERTEX}} \quad (4.83)
\]

**Proof.** Proposition 62 holds since each strongly connected component contains at least one vertex. \[
\]

**Proposition 63.**

\[
\text{\texttt{acyclic : NSCC = NVERTEX}} \quad (4.84)
\]

**Proof.** In a directed acyclic graph we have that each vertex corresponds to a strongly connected component involving only that vertex. \[
\]
Proposition 64.
\[ \text{NVERTEX} = 0 \Rightarrow \text{NSINK} = 0 \]  \hspace{1cm} (4.85)

*Proof.* By definition of NVERTEX and of NSINK.

Proposition 65.
\[ \text{NVERTEX} > 0 \Rightarrow \text{NSINK} < \text{NVERTEX} \]  \hspace{1cm} (4.86)

*Proof.* Holds since each sink must have a predecessor that cannot be a sink and since each vertex has at least one arc.

Proposition 66.
\[ \text{NVERTEX} = 0 \Rightarrow \text{NSOURCE} = 0 \]  \hspace{1cm} (4.87)

*Proof.* By definition of NVERTEX and of NSOURCE.

Proposition 67.
\[ \text{NVERTEX} > 0 \Rightarrow \text{NSOURCE} < \text{NVERTEX} \]  \hspace{1cm} (4.88)

*Proof.* Holds since each source must have a successor that cannot be a source and since each vertex has at least one arc.
4.3. **GRAPH INVARIANTS**

Graph invariants involving three parameters of a final graph

Proposition 68.

\[
\text{MIN}_N \neq \text{MAX}_N \Rightarrow \text{NARC} \geq \text{MIN}_N + \text{MAX}_N - 2 + (\text{MIN}_N = 1)
\]

(4.89)

Proof. (4.89) \(n - 1\) arcs are needed to connect \(n\) \((n > 1)\) vertices that all belong to a given connected component. Since we have two connected components, which respectively have \(\text{MIN}_N\) and \(\text{MAX}_N\) vertices, this leads to the previous inequality. When \(\text{MIN}_N\) is equal to one we need an extra arc.

Proposition 69.

\[
\text{MIN}_N \neq \text{MAX}_N \Rightarrow \text{NCC} \geq 2
\]

(4.91)

Proof. If \(\text{MIN}_N\) and \(\text{MAX}_N\) are different then they correspond for sure to at least two distinct connected components.

Proposition 70.

\[
\text{MIN}_N \neq \text{MAX}_N \Rightarrow \text{NVERTEX} \geq \text{MIN}_N + \text{MAX}_N
\]

(4.92)

Proof. Since we have at least two distinct connected components, which respectively have \(\text{MIN}_N\) and \(\text{MAX}_N\) vertices, this leads to the previous inequality.

Proposition 71.

\[
\text{MAX}_N \leq \max(\min(\text{MIN}_N, \text{NVERTEX} - \max(1, \text{MIN}_N)), \text{MAX}_N)
\]

(4.93)

Proof. On the one hand, if \(\text{NCC} \leq 1\), we have that \(\text{MAX}_N \leq \text{MIN}_N\). On the other hand, if \(\text{NCC} > 1\), we have that \(\text{NVERTEX} \geq \min(1, \text{MIN}_N) + \text{MAX}_N\) (i.e., \(\text{MAX}_N \leq \text{NVERTEX} - \max(1, \text{MIN}_N)\)). The result is obtained by taking the maximum value of the right-hand sides of the two inequalities.

Proposition 72.

\[
\text{MIN}_N \notin [\text{NVERTEX} - \max(1, \text{MAX}_N) + 1, \text{NVERTEX} - 1]
\]

(4.94)

Proof. On the one hand, if \(\text{NCC} \leq 1\), we have that \(\text{MIN}_N \geq \text{NVERTEX}\). On the other hand, if \(\text{NCC} > 1\), we have that \(\text{MIN}_N + \max(1, \text{MAX}_N) \leq \text{NVERTEX}\) (i.e., \(\text{MIN}_N \leq \text{NVERTEX} - \max(1, \text{MAX}_N)\)). The result follows.

Proposition 73.

\[
\text{NVERTEX} \notin [\text{MIN}_N + 1, \text{MIN}_N + \text{MAX}_N - 1]
\]

(4.95)
Proof. On the one hand, if $\text{NCC} \leq 1$, we have that $\text{NVERTEX} \leq \text{MIN}_\text{NCC}$. On the other hand, if $\text{NCC} > 1$, we have that $\text{NVERTEX} \geq \text{MIN}_\text{NCC} + \text{MAX}_\text{NCC}$. Since $\text{MIN}_\text{NCC} \leq \text{MIN}_\text{NCC} + \text{MAX}_\text{NCC}$ the result follows.

Proposition 74.

$$\text{if } \text{MIN}_\text{NCC} > 0$$
$$\quad \text{then } k_{\text{inf}} = \left\lfloor \frac{\text{NVERTEX} + \text{MIN}_\text{NCC}}{\text{MIN}_\text{NCC}} \right\rfloor \text{ else } k_{\text{inf}} = 1$$
$$\text{if } \text{MAX}_\text{NCC} > 0$$
$$\quad \text{then } k_{\text{sup}_1} = \frac{\text{NVERTEX} - 1}{\text{MAX}_\text{NCC}} \text{ else } k_{\text{sup}_1} = \text{NVERTEX}$$
$$\text{if } \text{MAX}_\text{NCC} < \text{MIN}_\text{NCC}$$
$$\quad \text{then } k_{\text{sup}_2} = \left\lfloor \frac{\text{MIN}_\text{NCC} - 2}{\text{MAX}_\text{NCC} - \text{MIN}_\text{NCC}} \right\rfloor \text{ else } k_{\text{sup}_2} = \text{NVERTEX}$$
$$k_{\text{sup}} = \min(k_{\text{sup}_1}, k_{\text{sup}_2})$$

\forall k \in [k_{\text{inf}}, k_{\text{sup}}]: \text{NVERTEX} \notin \left[k \cdot \text{MAX}_\text{NCC} + 1, (k + 1) \cdot \text{MIN}_\text{NCC} - 1\right]

(4.96)

Proof. We make the proof for $k \in \mathbb{N}$ (the interval $[k_{\text{inf}}, k_{\text{sup}}]$ is only used for restricting the number of intervals to check). We have that $\text{NVERTEX} \in [k \cdot \text{MIN}_\text{NCC}, k \cdot \text{MAX}_\text{NCC}]$. A forbidden interval $[k \cdot \text{MAX}_\text{NCC} + 1, (k + 1) \cdot \text{MIN}_\text{NCC} - 1]$ corresponds to an interval between the end of interval $[k \cdot \text{MIN}_\text{NCC}, k \cdot \text{MAX}_\text{NCC}]$ and the start of the next interval $[(k + 1) \cdot \text{MIN}_\text{NCC}, (k + 1) \cdot \text{MAX}_\text{NCC}]$. Since all intervals $[i \cdot \text{MIN}_\text{NCC}, i \cdot \text{MAX}_\text{NCC}]$ ($i < k$) end before $k \cdot \text{MAX}_\text{NCC}$ and since all intervals $[j \cdot \text{MIN}_\text{NCC}, j \cdot \text{MAX}_\text{NCC}]$ ($j > k$) start after $(k + 1) \cdot \text{MIN}_\text{NCC}$, they do not use any value in $[k \cdot \text{MAX}_\text{NCC} + 1, (k + 1) \cdot \text{MIN}_\text{NCC} - 1]$.

MAX, NARC, NCC

Proposition 75.

$$\text{NARC} \leq \text{NCC} \cdot \text{MAX}_\text{NCC}^2$$

(4.97)

$$\text{arc, gen} = \text{PATH} : \text{NARC} \leq \text{NCC} \cdot (\text{MAX}_\text{NCC} - 1)$$

(4.98)

Proof. On the one hand, (4.97) holds since the maximum number of arcs is achieved by taking $\text{NCC}$ connected components where each connected component is a clique involving $\text{MAX}_\text{NCC}$ vertices. On the other hand, (4.98) holds since a tree of $n$ vertices has $n - 1$ arcs.

Proposition 76.

$$\text{NARC} \geq \text{MAX}_\text{NCC} + \text{NCC} - 2$$

(4.99)

Proof. The minimum number of arcs is achieved by taking one connected component with $\text{MAX}_\text{NCC}$ vertices and $\text{MAX}_\text{NCC} - 1$ arcs as well as $\text{NCC} - 1$ connected components with a single vertex and a loop.
4.3. GRAPH INVARIANTS

**MAX, NCC, NARC, NVERTEX**

**Proposition 77.**

\[
\text{NARC} \leq \text{MAX}^2 \cdot \frac{\text{NVERTEX}}{\text{max}(1, \text{MAX})} + (\text{NVERTEX} \mod \text{max}(1, \text{MAX}))^2
\]

(4.100)

![Connected components, each of them involving MAX vertices](image)

![A connected component with NVERTEX mod MAX vertices](image)

Figure 4.1: Illustration of Proposition 77. A graph that achieves the maximum number of arcs according to the size of the largest connected component as well as to a fixed number of vertices \((\text{MAX} = 3, \text{NVERTEX} = 11, \text{NARC} = 3^2 \cdot \left\lceil \frac{11}{\text{max}(1, 3)} \right\rceil + (11 \mod \text{max}(1, 3))^2 = 31)\)

**Proof.** If \(\text{MAX} = 0\) we get \(\text{NARC} \leq 0\) which holds since the set of vertices is empty. We now assume that \(\text{MAX} > 0\). We first begin with the following claim:

Let \(G\) be a graph such that \(V(G) = \text{NCC}(G) \cdot \text{MAX}(G) \geq \text{MAX}(G)\), then there exists a graph \(G'\) such that \(V(G') = V(G)\), \(\text{MAX}(G') = \text{MAX}(G), \text{NCC}(G', \text{MAX}(G')) = \text{NCC}(G, \text{MAX}(G)) + 1\) and \(|E(G')| \leq |E(G')|\).

Proof of the claim

Let \((C_i)_{i \in [n]}\) be the connected components of \(G\) on less than \(\text{MAX}(G)\) vertices and such that \(|C_i| \geq |C_i+1|\). By hypothesis there exists \(k \leq n\) such that \(|\bigcup_{i=1}^{k-1} C_i| < \text{MAX}(G)\) and \(|\bigcup_{i=1}^{k} C_i| \geq \text{MAX}(G)\).

- Either \(|\bigcup_{i=1}^{k-1} C_i| = \text{MAX}(G)\), and then with \(G'\) such that \(G'\) restricted to the \(\bigcup_{i=1}^{k-1} C_i\) be a complete graph and \(G'\) restricted to \(V(G) - \bigcup_{i=1}^{k} C_i\) being exactly \(G\) restricted to \(V(G) - \bigcup_{i=1}^{k} C_i\) we obtain the claim.

- Or \(|\bigcup_{i=1}^{k-1} C_i| > \text{MAX}(G)\). Then \(C_k = C_k^1 \cup C_k^2\) such that \(|\bigcup_{i=1}^{k-1} C_i \cup C_k^1| = \text{MAX}(G)\) and \(|C_k^2| < |C_k^1|\) (notice that \(k \geq 2\)). Then with \(G'\) such that \(G'\) restricted to \((\bigcup_{i=1}^{k-1} C_i) \cup C_k^1\) is a complete graph and \(G'\) restricted to \(V(G) - ((\bigcup_{i=1}^{k-1} C_i) \cup C_k^1)\) is exactly \(G\) restricted to \(V(G) - ((\bigcup_{i=1}^{k-1} C_i) \cup C_k^1)\) we obtain the claim.

End of proof of the claim

We prove by induction on \(r(G) = |\frac{\text{NVERTEX}(G)}{\text{MAX}(G)}| - \text{NCC}(G, \text{MAX}(G))\), where \(G\) is any graph. For \(r(G) = 0\) the result holds (see Prop 44). Otherwise, since \(r(G) > 0\) we have that \(V(G) - \text{NCC}(G, \text{MAX}(G)) \cdot \text{MAX}(G) \geq \text{MAX}(G)\),
by the previous claim there exists $G'$ with the same number of vertices and the same number of vertices in the largest connected component, such that $r(G') = r(G) - 1$. Consequently the result holds by induction. \hfill \Box

**Proposition 78.**

\[
\text{NARC} \geq \text{MAX}_N \text{C} - 1 + \left\lfloor \frac{\text{NVERTEX} - \text{MAX}_N \text{C} + 1}{2} \right\rfloor \quad (4.101)
\]

**Proof.** Let $G$ be a graph, let $X$ be a maximal size connected component of $G$, then we have $G = G[X] \oplus G[V(G) - X]$. On the one hand, as $G[X]$ is connected, by setting $\text{NCC} = 1$ in 4.143 of Proposition 99, we have $|E(G[X])| \geq |X| - 1$, on the other hand, by Proposition 52, $|E(G[V(G) - X])| \geq \left\lceil \frac{|V(G) - X|}{2} \right\rceil$. Thus the result follows. \hfill \Box

**Proposition 79.**

\[
\text{NSINK} \leq N_{\text{C}} \cdot \max(0, \text{MAX}_N \text{C} - 1) \quad (4.102)
\]

**Proof.** Since a connected component contains at most $\text{MAX}_N \text{C}$ vertices and since it does not contain any isolated vertex a connected component involves at most $\text{MAX}_N \text{C} - 1$ sinks. Thus the result follows. \hfill \Box

**Proposition 80.**

\[
\text{NSOURCE} \leq N_{\text{C}} \cdot \max(0, \text{MAX}_N \text{C} - 1) \quad (4.103)
\]

**Proof.** Similar to Proposition 79. \hfill \Box

**Proposition 81.**

\[
\text{NVERTEX} \leq N_{\text{C}} \cdot \text{MAX}_N \text{C} \quad (4.104)
\]

**Proof.** The number of vertices is less than or equal to the number of connected components multiplied by the largest number of vertices in a connected component. \hfill \Box

**Proposition 82.**

\[
\text{NVERTEX} \geq \text{MAX}_N \text{C} + \max(0, N_{\text{C}} - 1) \quad (4.105)
\]

\[
\text{no loop: NVERTEX} \geq \text{MAX}_N \text{C} + \max(0, 2 \cdot N_{\text{C}} - 2) \quad (4.106)
\]

**Proof.** (4.105) The minimum number of vertices according to a fixed number of connected components $N_{\text{C}}$ such that one of the connected components contains $\text{MAX}_N \text{C}$ vertices is obtained as follows: we get $\text{MAX}_N \text{C}$ vertices from the connected component involving $\text{MAX}_N \text{C}$ vertices and one vertex for each remaining connected component. \hfill \Box
4.3. Graph Invariants

**Proposition 83.**

\[ \text{MIN}_{\text{NSCC}} \neq \text{MAX}_{\text{NSCC}} \Rightarrow \text{NARC} \geq \text{MIN}_{\text{NSCC}} + \text{MAX}_{\text{NSCC}} \]  
\[ (4.107) \]

Equivalence: \[ \text{MIN}_{\text{NSCC}} \neq \text{MAX}_{\text{NSCC}} \Rightarrow \]  
\[ \text{NARC} \geq \text{MIN}_{\text{NSCC}}^2 + \text{MAX}_{\text{NSCC}}^2 \]  
\[ (4.108) \]

**Proof.** (4.107) In a strongly connected component at least one arc has to leave each arc. Since we have two strongly connected components, which respectively have \( \text{MIN}_{\text{NSCC}} \) and \( \text{MAX}_{\text{NSCC}} \) vertices, this leads to the previous inequality.

**Proposition 84.**

\[ \text{MIN}_{\text{NSCC}} \neq \text{MAX}_{\text{NSCC}} \Rightarrow \text{NSCC} \geq 2 \]  
\[ (4.109) \]

**Proof.** Follows from the definitions of \( \text{MIN}_{\text{NSCC}} \) and of \( \text{MAX}_{\text{NSCC}} \).

**Proposition 85.**

\[ \text{MIN}_{\text{NSCC}} \neq \text{MAX}_{\text{NSCC}} \Rightarrow \text{NVERTEX} \geq \text{MIN}_{\text{NSCC}} + \text{MAX}_{\text{NSCC}} \]  
\[ (4.110) \]

**Proof.** Since we have at least two distinct strongly connected components, which respectively have \( \text{MIN}_{\text{NSCC}} \) and \( \text{MAX}_{\text{NSCC}} \) vertices, this leads to the previous inequality.

**Proposition 86.**

\[
\text{if } \text{MIN}_{\text{NSCC}} > 0 \\
\text{then } k_{\inf} = \left\lfloor \frac{\text{NVERTEX} + \text{MIN}_{\text{NSCC}}}{\text{MIN}_{\text{NSCC}}} \right\rfloor \text{ else } k_{\inf} = 1
\]

\[
\text{if } \text{MAX}_{\text{NSCC}} > 0 \\
\text{then } k_{\sup_1} = \left\lfloor \frac{\text{NVERTEX} - 1}{\text{MAX}_{\text{NSCC}}} \right\rfloor \text{ else } k_{\sup_1} = \text{NVERTEX}
\]

\[
\text{if } \text{MAX}_{\text{NSCC}} < \text{MIN}_{\text{NSCC}} \\
\text{then } k_{\sup_2} = \left\lfloor \frac{\text{MIN}_{\text{NSCC}} - 2}{\text{MAX}_{\text{NSCC}} - \text{MIN}_{\text{NSCC}}} \right\rfloor \text{ else } k_{\sup_2} = \text{NVERTEX}
\]

\[
k_{\sup} = \min(k_{\sup_1}, k_{\sup_2})
\]

\[ \forall k \in [k_{\inf}, k_{\sup}] : \text{NVERTEX} \notin [k \cdot \text{MAX}_{\text{NSCC}} + 1, (k + 1) \cdot \text{MIN}_{\text{NSCC}} - 1] \]  
\[ (4.111) \]

**Proof.** Similar to Proposition 74.
Proposition 87.

\[ \text{NVERTEX} \leq \text{NCC} \cdot \text{MAX}_\text{NSCC} \tag{4.112} \]

Proof. The largest number of vertices is obtained by putting within each connected component the number of vertices of the largest strongly connected component. \qed

Proposition 88.

\[ \text{NVERTEX} \leq \text{NSCC} \cdot \text{MAX}_\text{NSCC} \tag{4.113} \]

Proof. Since each strongly connected component contains at most \text{MAX}_\text{NSCC} vertices the total number of vertices is less than or equal to \text{NSCC} \cdot \text{MAX}_\text{NSCC}. \qed

Proposition 89.

\[ \text{NVERTEX} \geq \text{MAX}_\text{NSCC} + \max(0, \text{NSCC} - 1) \tag{4.114} \]

\[ \text{no loop} : \text{NVERTEX} \geq \text{MAX}_\text{NSCC} + \max(0, 2 \cdot \text{NSCC} - 2) \tag{4.115} \]

Proof. (4.114) The minimum number of vertices according to a fixed number of strongly connected components \text{NSCC} such that one of them contains \text{MAX}_\text{NSCC} vertices is equal to \text{MAX}_\text{NSCC} + \max(0, \text{NSCC} - 1). \qed

Proposition 90.

\[ \text{NARC} \leq \text{MIN}_\text{NCC}^2 + (\text{NVERTEX} - \text{MIN}_\text{NCC})^2 \tag{4.116} \]

\[ \text{arc}_\text{gen} = \text{CIRCUIT} : \text{NARC} \leq \text{NVERTEX} - 2 \cdot (\text{MIN}_\text{NCC} < \text{NVERTEX}) \tag{4.117} \]

\[ \text{arc}_\text{gen} = \text{CHAIN} : \text{NARC} \leq \text{NVERTEX} - 2 \cdot (\text{MIN}_\text{NCC} < \text{NVERTEX}) \tag{4.118} \]

\[ \text{arc}_\text{gen} = \text{CLIQUE}(\leq) : \text{NARC} \leq \frac{\text{MIN}_\text{NCC} \cdot (\text{MIN}_\text{NCC} + 1)}{2} + \frac{(\text{NVERTEX} - \text{MIN}_\text{NCC}) \cdot (\text{NVERTEX} - \text{MIN}_\text{NCC} + 1)}{2} \tag{4.119} \]

\[ \text{arc}_\text{gen} = \text{CLIQUE}(\geq) : \text{NARC} \leq \frac{\text{MIN}_\text{NCC} \cdot (\text{MIN}_\text{NCC} + 1)}{2} + \frac{(\text{NVERTEX} - \text{MIN}_\text{NCC}) \cdot (\text{NVERTEX} - \text{MIN}_\text{NCC} + 1)}{2} \tag{4.120} \]

\[ \text{arc}_\text{gen} = \text{CLIQUE}(<) : \text{NARC} \leq \frac{\text{MIN}_\text{NCC} \cdot (\text{MIN}_\text{NCC} - 1)}{2} + \frac{(\text{NVERTEX} - \text{MIN}_\text{NCC}) \cdot (\text{NVERTEX} - \text{MIN}_\text{NCC} - 1)}{2} \tag{4.121} \]

\[ \text{arc}_\text{gen} = \text{CLIQUE}(>) : \text{NARC} \leq \frac{\text{MIN}_\text{NCC} \cdot (\text{MIN}_\text{NCC} - 1)}{2} + \frac{(\text{NVERTEX} - \text{MIN}_\text{NCC}) \cdot (\text{NVERTEX} - \text{MIN}_\text{NCC} - 1)}{2} \tag{4.122} \]
4.3. GRAPH INVARIANTS

\[
\text{arc_gen} = \text{CLIQUE}(!) : \text{NARC} \leq \text{MIN}_\text{NCC}^2 - \text{MIN}_\text{NCC} + (\text{NVERTEX} - \text{MIN}_\text{NCC})^2 - (\text{NVERTEX} - \text{MIN}_\text{NCC}) \tag{4.123}
\]

\[
\text{arc_gen} = \text{CYCLE} : \text{NARC} \leq \text{NVERTEX} - 4 \cdot (\text{MIN}_\text{NCC} < \text{NVERTEX}) \tag{4.124}
\]

\[
\text{arc_gen} = \text{PATH} : \text{NARC} \leq \max(0, \text{MIN}_\text{NCC} - 1) + \max(0, \text{NVERTEX} - \text{MIN}_\text{NCC} - 1) \tag{4.125}
\]

**Proof.** (4.116) The maximum number of vertices according to a fixed number of vertices NVERTEX and to the fact there is a connected component with MIN_NCC vertices is obtained by:

- Building a connected component with MIN_NCC vertices and creating an arc between each pair of vertices.
- Building a connected component with all the NVERTEX - MIN_NCC remaining vertices and creating an arc between each pair of vertices.

\[\square\]

**Proposition 91.**

\[
\text{MIN}_\text{NCC} > 1 \Rightarrow \\
\text{NARC} \geq \left\lfloor \frac{\text{NVERTEX}}{\text{MIN}_\text{NCC}} \right\rfloor \cdot (\text{MIN}_\text{NCC} - 1) + \text{NVERTEX} \mod \text{MIN}_\text{NCC} \tag{4.126}
\]

**Proof.** Achieving the minimum number of arcs with a fixed number of vertices and with a minimum number of vertices greater than or equal to one in each connected component is achieved in the following way:

- Since the minimum number of arcs of a connected component of \(n\) vertices is \(n - 1\), splitting a connected component into \(k\) parts that all have more than one vertex saves \(k - 1\) arcs. Therefore we build a maximum number of connected components. Since each connected component has at least MIN_NCC vertices we get \(\left\lfloor \frac{\text{NVERTEX}}{\text{MIN}_\text{NCC}} \right\rfloor\) connected components.
- Since we cannot build a connected component with the rest of the vertices (i.e., NVERTEX mod MIN_NCC vertices left) we have to incorporate them in the previous connected components and this costs one arc for each vertex.

\[\square\]

When MIN_NCC = 1, note that Proposition 52 provides a lower bound on the number of arcs.
Proposition 92.
\[ \text{NVERTEX} \geq \text{NCC} \cdot \text{MIN NCC} \]  
\[ (4.127) \]

Proof. The smallest number of vertices is obtained by taking all connected components to their minimum number of vertices \( \text{MIN NCC} \).

Proposition 93.
\[ \text{NVERTEX} > \text{MIN NCC} \Rightarrow \text{NCC} \geq 2 \]  
\[ (4.128) \]

Proof. If all vertices do not fit within the smallest connected component then we have at least two connected components.

Proposition 94.
\[ \text{NARC} \leq \text{NVERTEX}^2 + \text{MIN NSCC}^2 - \text{NVERTEX} \cdot \text{MIN NSCC} \]  
\[ (4.129) \]

Proof. Achieving the maximum number of arcs, provided that we have at least one strongly connected component with \( \text{MIN NSCC} \) vertices, is done by:

- Building a first strongly connected component \( C_1 \) with \( \text{MIN NSCC} \) vertices and adding an arc between each pair of vertices of \( C_1 \).  
- Building a second strongly connected component \( C_2 \) with \( \text{NVERTEX} - \text{MIN NSCC} \) vertices and adding an arc between each pair of vertices of \( C_2 \).

Finally, we add an arc from every vertex of \( C_1 \) to every vertex of \( C_2 \). This leads to a total number of arcs of \( \text{MIN NSCC}^2 + (\text{NVERTEX} - \text{MIN NSCC})^2 + \text{MIN NSCC} \cdot (\text{NVERTEX} - \text{MIN NSCC}) \).

Proposition 95.
\[ \text{NVERTEX} \geq \text{NCC} \cdot \text{MIN NSCC} \]  
\[ (4.130) \]

Proof. The smallest number of vertices is obtained by putting within each connected component the number of vertices of the smallest strongly connected component.

Proposition 96.
\[ \text{NVERTEX} \geq \text{NSCC} \cdot \text{MIN NSCC} \]  
\[ (4.131) \]

Proof. Since each strongly connected component contains at least \( \text{MIN NSCC} \) vertices the total number of vertices is greater than or equal to \( \text{NSCC} \cdot \text{MIN NSCC} \).

Proposition 97.
\[ \text{NVERTEX} > \text{MIN NSCC} \Rightarrow \text{NSCC} \geq 2 \]  
\[ (4.132) \]

Proof. If all vertices do not fit within the smallest strongly connected component then we have at least two strongly connected components.
4.3. GRAPH INVARIANTS

**Proposition 98.**

\[
\text{NARC} \leq (\text{NVERTEX} - \text{NCC} + 1)^2 + \text{NCC} - 1
\]

\[\text{arc_gen = } CIRCUIT : \text{NARC} \leq \text{NVERTEX} - \text{NCC} + 1 - (\text{NCC} \neq 1)\]

\[\text{arc_gen = } \text{CHAIN} : \text{NARC} \leq 2 \cdot \text{NVERTEX} - 2 \cdot \text{NCC}\]

\[\text{arc_gen = } \text{CLIQUE}(\leq) : \text{NARC} \leq \text{NCC} - 1 + (\text{NVERTEX} - \text{NCC} + 1) \cdot (\text{NVERTEX} - \text{NCC} + 2)\]

\[\text{arc_gen = } \text{CLIQUE}(\geq) : \text{NARC} \leq \text{NCC} - 1 + (\text{NVERTEX} - \text{NCC} + 1) \cdot (\text{NVERTEX} - \text{NCC})\]

\[\text{arc_gen = } \text{CLIQUE}(<) : \text{NARC} \leq \text{NCC} - 1 + (\text{NVERTEX} - \text{NCC} + 1) \cdot (\text{NVERTEX} - \text{NCC})\]

\[\text{arc_gen = } \text{CLIQUE}(>) : \text{NARC} \leq \text{NCC} - 1 + (\text{NVERTEX} - \text{NCC} + 1)^2 - (\text{NVERTEX} - \text{NCC} + 1)\]

\[\text{arc_gen = } \text{CYCLE} : \text{NARC} \leq 2 \cdot \text{NVERTEX} - 2 \cdot \text{NCC} + 2 \cdot (\text{NCC} = 1)\]

\[\text{arc_gen = } \text{PATH} : \text{NARC} = \text{NVERTEX} - \text{NCC}\]

---

**Figure 4.2:** Illustration of Proposition 98. A graph that achieves the maximum number of arcs according to a fixed number of connected components as well as to a fixed number of vertices (NCC = 5, NVERTEX = 7, NARC = (7 - 5 + 1)^2 + 5 - 1 = 13)

**Proof.** (4.133) We proceed by induction on \(T(G) = \text{NVERTEX}(G) - |X| - (\text{NCC}(G) - 1)\), where \(X\) is any connected component of \(G\) of maximum cardinality. For \(T(G) = 0\) then either \(\text{NCC}(G) = 1\) and thus the formula is clearly true, or all the connected components of \(G\), but possibly \(X\), are reduced to one element. Since isolated vertices are not allowed, the formula holds.

Assume that \(T(G) \geq 1\). Then there exists \(Y\), a connected component of \(G\) distinct from \(X\), with more than one vertex. Let \(y \in Y\) and let \(G'\) be the graph such that \(V(G') = V(G)\) and \(E(G')\) is defined by:
4. FURTHER TOPICS

- For all $Z$ connected components of $G$ distinct from $X$ and $Y$ we have $G'[Z] = G[Z]$.
- With $X' = X \cup \{y\}$ and $Y' = Y - \{y\}$, we have $G'[Y'] = G[Y']$ and $E(G'[X']) = E(G[X]) \cup \{ (x, y), (y, x) \}$.

Clearly $|E(G')| - |E(G)| \geq 2 \cdot |X| + 1 - (2 \cdot |Y| - 1)$ and since $X$ is of maximal cardinality the difference is strictly positive. Now as $N\text{VERTEX}(G') = N\text{VERTEX}(G)$, $NCC(G') = NCC(G)$ and as $T(G') = T(G) - 1$ the result holds by induction hypothesis.

** Proposition 99. **

$$NARC \geq N\text{VERTEX} - NCC$$ \hspace{1cm} (4.143)

**equivalence:** $NCC > 0 \Rightarrow$

$$NARC \geq (N\text{VERTEX} \mod NCC) \cdot \left( \left \lfloor \frac{N\text{VERTEX}}{NCC} \right \rfloor + 1 \right)^2 + \left( NCC - N\text{VERTEX} \mod NCC \right) \cdot \left( \left \lfloor \frac{N\text{VERTEX}}{NCC} \right \rfloor + 1 \right)^2$$ \hspace{1cm} (4.144)

**Proof.** (4.143) By induction of the number of vertices. The formula holds for one vertex. Let $G$ a graph with $n + 1$ vertices $(n \geq 1)$. First assume there exists $x$ in $G$ such that $G - x$ has the same number of connected components than $G$. Since $NARC(G) \geq NARC(G - x) + 1$, and by induction hypothesis $NARC(G - x) \geq N\text{VERTEX}(G - x) - NCC(G - x)$ the result holds. Otherwise all connected components of $G$ are reduced to one vertex and the formula holds.

** NARC, NSCC, N\text{VERTEX} **

** Proposition 100. **

$$NARC \leq (N\text{VERTEX} - NSCC + 1) \cdot N\text{VERTEX} + \frac{NSCC \cdot (NSCC - 1)}{2}$$ \hspace{1cm} (4.145)

**equivalence:** $NARC \leq NSCC - 1 + (N\text{VERTEX} - NSCC + 1)^2$ \hspace{1cm} (4.146)

**Figure 4.3:** Illustration of Proposition 100(4.145). A graph that achieves the maximum number of arcs according to a fixed number of strongly connected components as well as to a fixed number of vertices ($NSCC = 5$, $N\text{VERTEX} = 6$, $NARC = (6 - 5 + 1) \cdot 6 + \frac{5 \cdot (5 - 1)}{2} = 22$)

**Proof.** For proving 4.145, it is easier to rewrite the formula as $NARC \leq (N\text{VERTEX} - (NSCC - 1))^2 + (NSCC - 1) \cdot (N\text{VERTEX} - (NSCC - 1)) + \frac{NSCC \cdot (NSCC - 1)}{2}$. We proceed by induction on $T(G) = N\text{VERTEX}(G) - |X| - (NSCC(G) - 1)$, where $X$ is any strongly connected component of $G$ of maximum cardinality.
4.3. GRAPh INVARIANTS

For $T(G) = 0$ then either $\text{NSCC}(G) = 1$ and thus the formula is clearly true, or all the strongly connected components of $G$, but possibly $X$, are reduced to one element. Since the maximum number of arcs in a directed acyclic graph of $n$ vertices is $\frac{n(n-1)}{2}$, and as the subgraph of $G$ induced by all the strongly connected components of $G$ excepted $X$ is acyclic, the formula clearly holds.

Assume that $T(G) \geq 1$, let $(X_i)_{i \in I}$ be the family of strongly connected components of $G$, and let $G_r$ be the reduced graph of $G$ induced by $(X_i)_{i \in I}$ (that is $V(G_r) = I$ and $\forall i_1, i_2 \in I, (i_1, i_2) \in E(G_r)$ if and only if $\exists x_1 \in X_{i_1}, \exists x_2 \in X_{i_2}$ such that $(x_1, x_2) \in E$). Consider $G'$ such that $V(G') = V(G)$ and $E(G')$ is defined by:

- For all strongly connected components $Z$ of $G$ we have $G'[Z] = G[Z]$.
- For $\sigma$ be any topological sort of $G_r$, $\forall x_i \in X_i, \forall x_j \in X_j, (x_i, x_j) \in E(G')$ whenever $i$ is less than $j$ with respect to $\sigma$.

Notice that $G'$ satisfies the following properties: $T(G') = T(G)$, $V(G') = V(G)$, $\text{NSCC}(G') = \text{NSCC}(G)$, $E(G) \subseteq E(G')$, $(X_i)_{i \in I}$ is still the family of strongly connected components of $G'$, and moreover, for every $i \in I$ and every $x_i \in X_i$ we have that $x_i$ is connected to any vertex outside $X_i$, that is the number of arcs incident to $x_i$ and incident to vertices outside $X_i$ is exactly $|V(G')| - |X_i|$.

Now, as $T(G') \geq 1$, there exists $Y$, a strongly connected component of $G'$ distinct from $X$, with more than one vertex. Let $y \in Y$ and let $G''$ be the graph such that $V(G'') = V(G')$ and $E(G'')$ is defined by:

- $G''[V(G) - \{y\}] = G'[V(G) - \{y\}]$.
- With $X' = X \cup \{y\}$, we have $G''[X'] = G'[X']$ and $E(G''[X']) = E(G'[X]) \cup (\bigcup_{x \in X'} \{(x,y),(y,x)\})$.
- Assume that $X = X_j$ for $j \in I$. Then $\forall i \in I - \{j\}, \forall x_i \in X_i, (x_i, y) \in E(G'')$ whenever $i$ is less than $j$ with respect to $\sigma$ and $(y, x_i) \in E(G'')$ whenever $j$ is less than $i$ with respect to $\sigma$.

Clearly $|E(G'')| - |E(G')| \geq 2|X| + 1 + |V(G')| - |X| - (2 \cdot |Y| - 1 + |V(G')| - |Y|) = |X| - |Y| + 2$ and since $X$ is of maximal cardinality the difference is strictly positive. As $E(G) \subseteq E(G'), |E(G')| - |E(G)|$ is also strictly positive. Now as $\text{NVERTEX}(G'') = \text{NVERTEX}(G'), \text{NSCC}(G'') = \text{NSCC}(G) = \text{NSCC}(G)$ and as $T(G'') = T(G') - 1 = T(G) - 1$ the result holds by induction hypothesis.

\textbf{Proposition 101.}

\[
\text{NARC} \geq \text{NVERTEX} - \left\lfloor \frac{\text{NSCC} - 1}{2} \right\rfloor
\]

\text{equivalence: NSCC} > 0 \Rightarrow

\[
\text{NARC} \geq \left(\text{NVERTEX} \mod \text{NSCC}\right) \cdot \left(\left\lfloor \frac{\text{NVERTEX}}{\text{NSCC}} \right\rfloor + 1\right)^2 + \\
\left(\text{NSCC} - \text{NVERTEX} \mod \text{NSCC}\right) \cdot \left\lfloor \frac{\text{NVERTEX}}{\text{NSCC}} \right\rfloor^2
\]

\textbf{Proof.} For proving part $4.147$ of Proposition 101 we proceed by induction on $\text{NSCC}(G)$. If $\text{NSCC}(G) = 1$ then, we have $\text{NARC}(G) \geq \text{NVERTEX}(G)$ (i.e., for one vertex this is true since every vertex has at least one arc, otherwise every vertex $v$ has an arc arriving on $v$ as well as an arc starting from $v$, thus we have $\text{NARC} \geq 2 \cdot \text{NVERTEX}$). If $\text{NSCC}(G) > 1$ let $X$ be a strongly connected component of $G$. Then $\text{NARC}(G) \geq \text{NARC}(G[V(G) - X]) + \text{NARC}(G[X])$. By induction hypothesis $\text{NARC}(G[V(G) - X]) \geq |V(G) - X| -
4. FURTHER TOPICS

Figure 4.4: Illustration of Proposition 4.147. A graph that achieves the minimum number of arcs according to a fixed number of strongly connected components as well as to a fixed number of vertices (\(\text{NSCC} = 7\), \(\text{NVERTEX} = 10\), \(\text{NARC} = 10 - \left\lfloor \frac{7}{2} \right\rfloor = 7\)).

Thus \(\left\lfloor \frac{\text{NSCC}(G[V(G) - X]) - 1}{2} \right\rfloor\), thus \(\text{NARC}(G[V(G) - X]) \geq |V(G) - X| - \left\lfloor \frac{(\text{NSCC}(G)-1)}{2} \right\rfloor\).

Since \(\text{NARC}(G[X]) \geq |X|\) we obtain \(\text{NARC}(G) \geq |V(G)| - \left\lfloor \frac{(\text{NSCC}(G)-1)}{2} \right\rfloor\), and thus the result holds.

**Proposition 102.**

\[
\text{equivalence : } \text{NVERTEX} > 0 \Rightarrow \text{NSCC} \geq \left\lfloor \frac{\text{NVERTEX}^2}{\text{NARC}} \right\rfloor
\]

**Proof.** As shown in [68], a lower bound for the minimum number of equivalence classes (e.g., strongly connected components) is the independence number of the graph and the right-hand side of Proposition 102 corresponds to a lower bound of the independence number proposed by Turán [421].

**Proposition 103.**

\[
\text{equivalence : } \text{NVERTEX} > 0 \Rightarrow \text{NSCC} \geq \left\lfloor \frac{2 \cdot \text{NVERTEX} - \frac{\text{NARC} \cdot \text{NVERTEX}}{\text{NARC}} + 1}{\text{NARC} \cdot \text{NVERTEX}} \right\rfloor
\]

**Proof.** See [211] and [174].

**Proposition 104.**

\[
\text{NARC} \leq (\text{NVERTEX} - \text{NSINK}) \cdot \text{NVERTEX}
\]

**Proof.** The maximum number of arcs is achieved by the following pattern: for all non-sink vertices we have an arc to all vertices.

**Proposition 105.**

\[
\text{NARC} \geq \text{NSINK} + \max(0, \text{NVERTEX} - 2 \cdot \text{NSINK})
\]

**Proof.** Recall that for \(x \in V(G)\), we have that \(d_G^+(x) + d_G^-(x) \geq 1\). If \(x\) is a sink then \(d_G^-(x) \geq 1\), consequently \(\text{NARC}(G) \geq \text{NSINK}(G)\). If \(x\) is not a sink then \(d_G^+(x) \geq 1\), consequently \(\text{NARC}(G) \geq |V(G)| - \text{NSINK}(G)\).

Two graphs that achieve the minimum number of arcs according to a fixed number of sources as well as to a fixed number of vertices: (A) NSOURCE = 3, NVERTEX = 5, NARC = 3 + max(0, 5 − 2 · 3) = 3; (B) NSOURCE = 3, NVERTEX = 9, NARC = 3 + max(0, 9 − 2 · 3) = 6.
NSCC, NSINK, NSOURCE

Proposition 108.

\[ \text{NSCC} \geq \text{NSINK} + \text{NSOURCE} \quad (4.155) \]

Proof. Since sinks and sources cannot belong to a circuit and since they cannot coincide (i.e., because isolated vertices are not allowed) the result follows. \qed

NSINK, NSOURCE, NVERTEX

Proposition 109.

\[ \text{NVERTEX} \geq \text{NSINK} + \text{NSOURCE} \quad (4.156) \]

Proof. No vertex can be both a source and a sink (isolated vertices are removed). \qed
Graph invariants involving four parameters of a final graph

**Proposition 110.** Let \( \alpha \) denote \( \max(0, NCC - 1) \).

\[
NARC \leq \alpha \cdot \text{MAX}_{NCC}^2 + \text{MIN}_{NCC}^2
\]  
(4.157)

arc_gen = \( CIRCUIT \) : \( \text{NARC} \leq \alpha \cdot \text{MAX}_{NCC} + \text{MIN}_{NCC} \)  
(4.158)

arc_gen = \( CHAIN \) : \( \text{NARC} \leq \alpha \cdot (2 \cdot \text{MAX}_{NCC} - 2) + 2 \cdot \text{MIN}_{NCC} - 2 \)  
(4.159)

\[
\alpha \cdot \frac{\text{MAX}_{NCC}(\text{MAX}_{NCC} + 1)}{2} + \frac{\text{MIN}_{NCC}(\text{MIN}_{NCC} + 1)}{2}
\]  
(4.160)

\[
\alpha \cdot \frac{\text{MAX}_{NCC}(\text{MAX}_{NCC} - 1)}{2} + \frac{\text{MIN}_{NCC}(\text{MIN}_{NCC} - 1)}{2}
\]  
(4.161)

Proof. We construct \( NCC - 1 \) connected components with \( \text{MAX}_{NCC} \) vertices and one connected component with \( \text{MIN}_{NCC} \) vertices. The quantity \( \max(1, n - 1) \) corresponds to the minimum number of arcs in a connected component of \( n \) vertices according to the fact that we use the arc generator \( CIRCUIT, CHAIN, CLIQUE(\leq), CLIQUE(\geq), CLIQUE(<), CLIQUE(>) \). \( CIRCLE \) or \( PATH \). \( \square \)

**Proposition 111.**

\( NCC > 0 \Rightarrow \text{NARC} \geq (NCC - 1) \cdot \max(1, \text{MIN}_{NCC} - 1) + \max(1, \text{MAX}_{NCC} - 1) \)  
(4.165)

arc_gen = \( PATH \) : \( \text{NARC} \geq \max(0, \text{NCC} - 1) \cdot (\text{MIN}_{NCC} - 1) + \text{MAX}_{NCC} - 1 \)  
(4.166)

Proof. \( (4.165) \) We construct \( NCC - 1 \) connected components with \( \text{MIN}_{NCC} \) vertices and one connected component with \( \text{MAX}_{NCC} \) vertices. The quantity \( \max(1, n - 1) \) corresponds to the minimum number of arcs in a connected component of \( n \) (\( n > 0 \)) vertices. \( \square \)
Proposition 112.
\[
\text{NVERTEX} \leq \max(0, \text{NCC} - 1) \cdot \text{MAX} \text{NCC} + \text{MIN} \text{NCC}
\] (4.167)

Proof. Derived from the definitions of \text{MIN} \text{NCC} and \text{MAX} \text{NCC}.

Proposition 113.
\[
\text{NVERTEX} \geq \max(0, \text{NCC} - 1) \cdot \text{MIN} \text{NCC} + \text{MAX} \text{NCC}
\] (4.168)

Proof. Derived from the definitions of \text{MIN} \text{NCC} and \text{MAX} \text{NCC}.

Proposition 114.
\[
\text{NSINK} + \text{NSOURCE} \leq \text{NCC} \cdot \max(0, \text{MAX} \text{NCC} - 1)
\] (4.169)

Proof. Since a connected component contains at most \text{MAX} \text{NCC} vertices and since it does not contain any isolated vertex and since a same vertex cannot be both a sink and a source a connected component involves at most \text{MAX} \text{NCC} - 1 sinks and sources all together. Thus the result follows.

Proposition 115.
\[
\text{NARC} \leq \max(0, \text{NSCC} - 1) \cdot \text{MAX} \text{NSCC}^2 + \text{MIN} \text{NSCC}^2 + \max(0, \text{NSCC} - 1) \cdot \text{MIN} \text{NSCC} \cdot \text{MAX} \text{NSCC} + \text{MAX} \text{NSCC}^2 \cdot \frac{\max(0, \text{NSCC} - 2) \cdot \max(0, \text{NSCC} - 1)}{2}
\] (4.170)

Proof. We assume that we have at least two strongly connected components (the case with one being obvious). Let \((\text{SCC}_i)_{i \in \text{NCC}(G)}\) be the family of strongly connected components of \(G\). Then \(|E(G)| \leq \sum_{i \in \text{NCC}(G)} |E(G[\text{SCC}_i])| + k\), where \(k\) is the number of arcs between the distinct strongly connected components of \(G\). For any strongly connected component \(\text{SCC}_i\) the number of arcs it has with the other strongly connected components is bounded by \(|\text{SCC}_i| \cdot (|V(G)| - |\text{SCC}_i|)\). Consequently, \(k \leq \frac{1}{2} \cdot \sum_{i \in \text{NCC}(G)} |\text{SCC}_i| \cdot (|V(G)| - |\text{SCC}_i|)\). W.l.o.g. we assume \(|\text{SCC}_1| = \text{MIN} \text{NCC}\). Then we get \(k \leq \frac{1}{2} \cdot (\text{MIN} \text{NCC} \cdot (\text{NCC} - 1) \cdot \text{MAX} \text{NCC} + \text{MAX} \text{NCC} \cdot ((\text{NCC} - 2) \cdot \text{MAX} \text{NCC} + \text{MIN} \text{NCC}))\).

Proposition 116.
\[
\text{NARC} \geq \max(0, \text{NSCC} - 1) \cdot \text{MIN} \text{NSCC} + \text{MAX} \text{NSCC}
\] (4.171)

Proof. Let \((\text{SCC}_i)_{i \in \text{NCC}(G)}\) be the family of strongly connected components of \(G\), as \(|E(G)| \geq \sum_{i \in \text{NCC}(G)} |E(G[\text{SCC}_i])|\), we obtain the result since in a strongly connected graph the number of edges is at least its number of vertices.
4.3. GRAPH INVARIANTS

**Proposition 117.**

\[ \text{NVERTEX} \leq \max(0, \text{NSCC} - 1) \cdot \text{MAX_NSCC} + \text{MIN_NSCC} \]  

(4.172)

*Proof.* Derived from the definitions of MIN_NSCC and MAX_NSCC.

**Proposition 118.**

\[ \text{NVERTEX} \geq \max(0, \text{NSCC} - 1) \cdot \text{MIN_NSCC} + \text{MAX_NSCC} \]  

(4.173)

*Proof.* Derived from the definitions of MIN_NSCC and MAX_NSCC.

**Proposition 119.** Let \( \alpha, \beta \) and \( \gamma \) respectively denote \( \max(0, \text{NCC} - 1) \), \( \text{NVERTEX} - \alpha \cdot \text{MIN_NCC} \) and \( \text{MIN_NCC} \).

\[ \text{NARC} \leq \alpha \cdot \gamma^2 + \beta^2 \]  

(4.174)

\[ \text{arc}_\text{gen} \in \{\text{CLIQUE}(\leq), \text{CLIQUE}(\geq)\} : \text{NARC} \leq \alpha \cdot \frac{\gamma \cdot (\gamma + 1)}{2} + \frac{\beta \cdot (\beta + 1)}{2} \]  

(4.175)

\[ \text{arc}_\text{gen} \in \{\text{CLIQUE}(<), \text{CLIQUE}(>)\} : \text{NARC} \leq \alpha \cdot \frac{\gamma \cdot (\gamma - 1)}{2} + \frac{\beta \cdot (\beta - 1)}{2} \]  

(4.176)

\[ \text{arc}_\text{gen} = \text{CLIQUE}(\neq) : \text{NARC} \leq \alpha \cdot \gamma \cdot (\gamma - 1) + \beta \cdot (\beta - 1) \]  

(4.177)

Figure 4.7: Illustration of Proposition 119(4.174). Graph that achieves the maximum number of arcs according to a minimum number of vertices in a connected component, to a number of connected components, as well as to a fixed number of vertices (MIN_NCC = 2, NCC = 5, NVERTEX = 11, NARC = (11 - (5 - 1) \cdot 2)^2 + (5 - 1) \cdot 2^2 = 25)

*Proof.* For proving inequality 4.174 we proceed by induction on the number of vertices of \( G \). First note that if all the connected components are reduced to one element the result is obvious. Thus we assume that the number of vertices in the maximal sized connected component of \( G \) is at least 2. Let \( x \) be an element of the maximal sized connected component of \( G \). Then, \( G - x \) satisfies \( \alpha(G - x) = \alpha(G), \gamma(G - x) = \gamma(G) \) and \( \beta(G - x) = \beta(G) - 1 \). Since by induction hypothesis \( |E(G - x)| \leq \alpha(G - x) \cdot \gamma(G - x)^2 + \beta(G - x)^2 \), and since the number of arcs of \( G \) incident to \( x \) is at most \( 2 \cdot (\beta(G) - 1) + 1 \), we have that \( |E(G)| \leq \alpha(G) \cdot \gamma(G)^2 + (\beta(G) - 1)^2 + 2 \cdot (\beta(G) - 1) + 1 \). And thus the result follows. \( \square \)
Proposition 120.

\[ \text{NARC} \leq \text{NCC} - 1 + (\text{NVERTEX} - \text{NSCC} + 1) \cdot (\text{NVERTEX} - \text{NCC} + 1) + \frac{\text{NSCC} - \text{NCC} + 1 \cdot (\text{NSCC} - \text{NCC})}{2} \]  

(4.178)

Figure 4.8: Illustration of Proposition 120. A graph that achieves the maximum number of arcs according to a fixed number of connected components, to a fixed number of strongly connected components as well as to a fixed number of vertices (NCC = 3, NSCC = 6, NVERTEX = 7, NARC = 3 − 1 + (7 − 6 + 1) · (7 − 3 + 1) + \frac{(6−3+1)\cdot(6−3)}{2} = 18).

Proof. We proceed by induction on \( T(G) = \text{NVERTEX}(G) - |X| - (\text{NCC}(G) - 1) \), where \( X \) is any connected component of \( G \) of maximum cardinality. For \( T(G) = 0 \) then either \( \text{NCC}(G) = 1 \) and thus the formula is clearly true, by Proposition 4.145 or all the connected components of \( G \), but possibly \( X \), are reduced to one element. Since isolated vertices are not allowed, again by Proposition 4.145 applied on \( G[X] \), the formula holds indeed \( \text{NVERTEX}(G[X]) = \text{NVERTEX}(G) - (\text{NCC}(G) - 1) \) and \( \text{NSCC}(G[X]) = \text{NSCC}(G) - (\text{NCC}(G) - 1) \).

Assume that \( T(G) \geq 1 \). Then there exists \( Y \), a connected component of \( G \) distinct from \( X \), with more than one vertex.

- Firstly assume that \( G[Y] \) is strongly connected. Let \( y \in Y \) and let \( G' \) be the graph such that \( V(G') = V(G) \) and \( E(G') \) is defined by:

  - For all \( Z \) connected components of \( G \) distinct from \( X \) and \( Y \) we have \( G'[Z] = G[Z] \).
  - With \( X' = X \cup (Y - \{y\}) \) and \( Y' = \{y\} \), we have \( E(G'[Y']) = \{(y, y)\} \), \( E(G'[X']) = E(G[X]) \cup \{(z, x) : z \in Y - \{y\}, x \in X\} \cup \{(z, t) : z, t \in Y - \{y\}\} \).

Clearly we have that \( |E(G')| - |E(G)| \geq (|Y| - 1) \cdot |X| - 2 \cdot (|Y| - 1) \) and since \( |X| \geq |Y| \geq 2 \), the difference is positive or null. Now as \( \text{NVERTEX}(G') = \text{NVERTEX}(G), \text{NCC}(G') = \text{NCC}(G), \text{NSCC}(G') = \text{NSCC}(G) \) (since \( G'[Y - \{y\}] \) is strongly connected because \( E(G'[Y - \{y\}]) = \{(z, t) : z, t \in Y - \{y\}\} \).
and since the reduced graph of the strongly connected components of \( G'[X'] \) is exactly the reduced graph of the strongly connected components of \( G[X] \) to which a unique source has been added) and as \( T(G') \leq T(G) - 1 \), the result holds by induction hypothesis.

- Secondly assume that \( G[Y] \) is not strongly connected. Let \( Z \subset Y \) such that \( Z \) is a strongly connected component of \( G[Y] \) corresponding to a source in the reduced graph of the strongly connected components of \( G[Y] \). Let \( G' \) be the graph such that \( V(G') = V(G) \) and \( E(G') \) is defined by:

  - For all \( W \) connected components of \( G \) distinct from \( X \) and \( Y \) we have \( G'[W] = G[W] \).
  - With \( X' = X \cup Z \) and \( Y' = Y - Z \), we have \( E(G'[Y']) = E(G[Y']) \) if \(|Y'| > 1 \) and \( E(G'[Y']) = \{(y,y)\} \) if \( Y' = \{y\} \). \( E(G'[X']) = E(G[X]) \cup \{(z,x) : z \in Z, x \in X\} \).

Clearly we have that \( |E(G')| - |E(G)| \geq |Z| \cdot |X| - |Z| \cdot (|Y| - |Z|) \) and since \(|X| > |Y| - |Z| \), the difference is strictly positive. Now as \( N\text{NVERTEX}(G') = N\text{NVERTEX}(G), N\text{CC}(G') = N\text{CC}(G), N\text{NSCC}(G') = N\text{NSCC}(G) \) and as \( T(G') \leq T(G) - 1 \), the result holds by induction hypothesis.

\[ \Box \]

**Proposition 121.**

\[ N\text{ARC} \geq N\text{NVERTEX} - \max(0, \min(N\text{CC}, N\text{NSCC} - N\text{CC})) \]  \hspace{1cm} (4.179)

**Proof.** We prove that the invariant is valid for any digraph \( G \). First notice that for an operational behaviour, since we cannot assume that Proposition 55 (i.e., \( N\text{CC}(G) \leq N\text{NSCC}(G) \)) was already triggered, we use the \( \max \) operator. But since any strongly connected component is connected, then \( N\text{NSCC}(G) - N\text{CC}(G) \) is never negative. Consequently we only show by induction on \( N\text{NSCC}(G) \) that \( N\text{ARC}(G) \geq N\text{NVERTEX}(G) - \min(N\text{CC}(G), N\text{NSCC}(G) - N\text{CC}(G)) \). To begin notice that if \( X \) is a strongly (non void) connected component then either \( N\text{ARC}(G[X]) \geq |X| \) or \( N\text{ARC}(G[X]) = 0 \) and in this latter case we have that both \(|X| = 1 \) and \( X \) is strictly included in a connected component of \( G \) (recall that isolated vertices are not allowed). Thus we can directly assume that \( N\text{NSCC}(G) = k > 1 \).

First, consider that there exists a connected component of \( G \), say \( X \), which is also strongly connected. Let \( G' = G - X \), consequently we have \( N\text{NSCC}(G') = N\text{NSCC}(G) - 1 \), \( N\text{CC}(G') = N\text{CC}(G) - 1 \), \( N\text{NVERTEX}(G') = N\text{NVERTEX}(G) - |X| \), and \( N\text{ARC}(G') \geq |X| + N\text{ARC}(G') \). Then \( N\text{ARC}(G') \geq |X| + N\text{NVERTEX}(G') - \min(N\text{CC}(G'), N\text{NSCC}(G') - N\text{CC}(G')) \) and thus \( N\text{ARC}(G) \geq N\text{NVERTEX}(G) - \min(N\text{CC}(G') - 1, N\text{NSCC}(G) - N\text{CC}(G)) \), which immediately gives the result.

Second consider that any strongly connected component is strictly included in a connected component of \( G \). Then, either there exists a strongly connected component \( X \) such that \(|X| \geq 2 \). Let \( G' = G - X \), consequently we have \( N\text{NSCC}(G') = N\text{NSCC}(G) - 1 \), \( N\text{CC}(G') = N\text{CC}(G) \), \( N\text{NVERTEX}(G') = N\text{NVERTEX}(G) - |X| \), and \( N\text{ARC}(G') \geq |X| + 1 + N\text{ARC}(G') \). Then \( N\text{ARC}(G') \geq |X| + 1 + N\text{NVERTEX}(G') - \min(N\text{CC}(G'), N\text{NSCC}(G') - N\text{CC}(G')) \) and thus \( N\text{ARC}(G) \geq N\text{NVERTEX}(G) + 1 - \min(N\text{CC}(G), N\text{NSCC}(G) - N\text{CC}(G)) \), which immediately gives the result. Or, all the strongly connected components are reduced to one element, so we have \( N\text{NSCC}(G) = N\text{NVERTEX}(G) \), and thus we obtain that \( N\text{NVERTEX}(G) - \min(N\text{CC}(G), N\text{NSCC}(G) - N\text{CC}(G)) = \min(N\text{CC}(G), N\text{NVERTEX}(G) - N\text{CC}(G)) \), which gives the result by, for example, Proposition 99 (4.143).

\[ \Box \]

This bound is tight: take, for example, any circuit.
Proposition 122.

\[ \text{NARC} \leq \text{NVERTEX}^2 - \text{NVERTEX} \cdot \text{NSOURCE} \\
- \text{NVERTEX} \cdot \text{NSINK} + \text{NSOURCE} \cdot \text{NSINK} \]

(4.180)

Proof. Since the maximum number of arcs of a digraph is \( \text{NVERTEX}^2 \), and since:

- No vertex can have a source as a successor we lose \( \text{NVERTEX} \cdot \text{NSOURCE} \) arcs,
- No sink can have a successor we lose \( \text{NVERTEX} \cdot \text{NSINK} \) arcs.

In these two sets of arcs we count twice the arcs from the sinks to the sources, so we finally get a maximum number of arcs corresponding to the right-hand side of the inequality to prove. \( \square \)
4.3. GRAPH INVARIANTS

Graph invariants involving five parameters of a final graph

$$\text{MAX, MIN, NARC, NCC, NVERTEX}$$

**Proposition 123.**

**Let:**

- $$\Delta = \text{NVERTEX} - \text{NCC} \cdot \text{MIN}.$$
- $$\delta = \lceil \frac{\Delta}{\text{max}(1, \text{MAX} - \text{MIN})} \rceil.$$
- $$r \equiv \Delta \mod \max(1, \text{MAX} - \text{MIN}),$$
- $$\epsilon = (r > 0).$$

$$\Delta = 0 \lor (\text{MAX} \neq \text{MIN} \land \delta + \epsilon \leq \text{NCC}) \quad (4.181)$$

$$\text{NARC} \leq (\text{NCC} - \delta - \epsilon) \cdot \text{MIN}^2 + \epsilon \cdot (\text{MIN} + r)^2 + \delta \cdot \text{MAX}^2$$

$$\quad (4.182)$$

Proposition 123 is currently a conjecture.

$$\text{MIN, NARC, NCC, NSCC, NVERTEX}$$

**Proposition 124.**

$$\text{NARC} \leq (\text{NCC} - 1) \cdot \max(1, (\text{MIN} - 1)) +$$

$$\frac{(\text{NVERTEX} - \text{NSCC} + 1) \cdot (\text{NVERTEX} - \text{NCC} + 1) +$$

$$\frac{(\text{NSCC} - \text{NCC} + 1) \cdot (\text{NSCC} - \text{NCC})}{2}}{2}$$

$$\quad (4.183)$$

Proposition 124 is currently a conjecture.
Graph invariants relating two parameters of two final graphs

\[ \text{MAX\_NCC}_1, \text{MIN\_NCC}_1 \]

**Proposition 125.**

\( vpartition \land \text{consecutive\_loops\_are\_connected} : \text{MIN\_NCC}_1 \notin [\text{NVERTEX\_INITIAL} - \text{MAX\_NCC}_1, \text{MAX\_NCC}_1 - 1] \) \hspace{1cm} (4.184)

**Proof.** We show that the conjunction \( \text{MIN\_NCC}_1 \geq \text{NVERTEX\_INITIAL} - \text{MAX\_NCC}_1 \) and \( \text{MIN\_NCC}_1 \leq \text{MAX\_NCC}_1 - 1 \) leads to a contradiction.

Since \( \text{MIN\_NCC}_1 \leq \text{MAX\_NCC}_1 - 1 \) we have that \( \text{MIN\_NCC}_1 \neq \text{MAX\_NCC}_1 \) and the minimum required size for the different groups is \( \text{MIN\_NCC}_1 + 1 + \text{MAX\_NCC}_1 \). This minimum required size should not exceed the number of vertices \( \text{NVERTEX\_INITIAL} \) of the initial graph. But since, by hypothesis, \( \text{MIN\_NCC}_1 \geq \text{NVERTEX\_INITIAL} - \text{MAX\_NCC}_1 \), this is impossible. \( \square \)

\[ \text{MAX\_NCC}_2, \text{MIN\_NCC}_2 \]

**Proposition 126.**

\( vpartition \land \text{consecutive\_loops\_are\_connected} : \text{MIN\_NCC}_2 \notin [\text{NVERTEX\_INITIAL} - \text{MAX\_NCC}_2, \text{MAX\_NCC}_2 - 1] \) \hspace{1cm} (4.185)

**Proof.** Similar to Proposition 125. \( \square \)

\[ \text{MAX\_NCC}_1, \text{NCC}_2 \]

**Proposition 127.**

\( vpartition : \text{MAX\_NCC}_1 < \text{NVERTEX\_INITIAL} \iff \text{NCC}_2 > 0 \) \hspace{1cm} (4.186)
\( apartition : \text{MAX\_NCC}_1 < \text{NVERTEX\_INITIAL} \iff \text{NCC}_2 > 0 \) \hspace{1cm} (4.187)

**Proof.** (4.186) Since we have the precondition \( vpartition \), we know that each vertex of the initial graph belongs to the first or to the second final graphs (but not to both).

1. On the one hand, if the largest connected component of the first final graph cannot contain all the vertices of the initial graph, then the second final graph has at least one connected component.
2. On the other hand, if the second final graph has at least one connected component then the largest connected component of the first final graph cannot be equal to the initial graph.

(4.187) holds for a similar reason. \( \square \)

\[ \text{MAX\_NCC}_2, \text{NCC}_1 \]

**Proposition 128.**

\( vpartition : \text{MAX\_NCC}_2 < \text{NVERTEX\_INITIAL} \iff \text{NCC}_1 > 0 \) \hspace{1cm} (4.188)
\( apartition : \text{MAX\_NCC}_2 < \text{NVERTEX\_INITIAL} \iff \text{NCC}_1 > 0 \) \hspace{1cm} (4.189)

**Proof.** Similar to Proposition 127. \( \square \)
4.3. GRAPH INVARIANTS

\[ \text{MIN}_{\text{NCC}}_1, \text{NCC}_2 \]

**Proposition 129.**

\[ \text{vpartition} : \text{MIN}_{\text{NCC}}_1 < \text{NVERTEX}_{\text{INITIAL}} \iff \text{NCC}_2 > 0 \] \hfill (4.190)

**Proof.** Since we have the precondition \text{vpartition}, we know that each vertex of the initial graph belongs to the first or to the second final graphs (but not to both).

1. On the one hand, if the smallest connected component of the first final graph cannot contain all the vertices of the initial graph, then the second final graph has at least one connected component.
2. On the other hand, if the second final graph has at least one connected component then the smallest connected component of the first final graph cannot be equal to the initial graph.

\[ \text{MIN}_{\text{NCC}}_2, \text{NCC}_1 \]

**Proposition 130.**

\[ \text{vpartition} : \text{MIN}_{\text{NCC}}_2 < \text{NVERTEX}_{\text{INITIAL}} \iff \text{NCC}_1 > 0 \] \hfill (4.191)

**Proof.** Similar to Proposition 129.

\[ \text{NARC}_1, \text{NARC}_2 \]

**Proposition 131.**

\[ \text{apartition} \land \text{arc_gen} = \text{PATH} : \text{NARC}_1 + \text{NARC}_2 = \text{NVERTEX}_{\text{INITIAL}} - 1 \] \hfill (4.192)

**Proof.** Holds since each arc of the initial graph belongs to one of the two final graphs and since the initial graph has \text{NVERTEX}_{\text{INITIAL}} - 1 arcs.

\[ \text{NCC}_1, \text{NCC}_2 \]

**Proposition 132.**

\[ \text{apartition} \land \text{arc_gen} = \text{PATH} : |\text{NCC}_1 - \text{NCC}_2| \leq 1 \] \hfill (4.193)

\[ \text{vpartition} \land \text{consecutive_loops_are_connected} : |\text{NCC}_1 - \text{NCC}_2| \leq 1 \] \hfill (4.194)

**Proof.** Holds because the two initial graphs correspond to a path and because consecutive connected components do not come from the same graph constraint.

**Proposition 133.**

\[ \text{apartition} \land \text{arc_gen} = \text{PATH} : \text{NCC}_1 + \text{NCC}_2 < \text{NVERTEX}_{\text{INITIAL}} \] \hfill (4.195)

**Proof.** Holds because the initial graph is a path.

\[ \text{NVERTEX}_1, \text{NVERTEX}_2 \]

**Proposition 134.**

\[ \text{vpartition} : \text{NVERTEX}_1 + \text{NVERTEX}_2 = \text{NVERTEX}_{\text{INITIAL}} \] \hfill (4.196)

**Proof.** By definition of \text{vpartition} each vertex of the initial graph belongs to one of the two final graphs (but not to both).
Graph invariants relating three parameters of two final graphs

\[ \text{MAX}_1, \text{MIN}_1, \text{MIN}_2 \]

**Proposition 135.**

\[
\text{apartition} \land \text{arc}_\text{gen} = \text{PATH} : \\
\max(2, \text{MIN}_1) + \max(3, \text{MIN}_1 + 1, \text{MAX}_1) + \\
\max(2, \text{MIN}_2) - 2 > \text{NVERTEX}_{\text{INITIAL}} \Rightarrow \text{MIN}_1 = \text{MAX}_1
\]

(4.197)

**Proof.** The quantity \( \max(2, \text{MIN}_1) + \max(3, \text{MIN}_1 + 1, \text{MAX}_1) + \max(2, \text{MIN}_2) - 2 \) corresponds to the minimum number of variables needed for building two non-empty connected components of respective size \( \text{MIN}_1 \) and \( \text{MAX}_1 \) such that \( \text{MAX}_1 \) is strictly greater than \( \text{MIN}_1 \). If this quantity is greater than the total number of variables we have that \( \text{MIN}_1 = \text{MAX}_1 \). \( \square \)

**Proposition 136.**

\[
\text{vpartition} \land \text{consecutive}_\text{loops}_\text{are}_\text{connected} : \\
\max(1, \text{MIN}_1) + \max(2, \text{MIN}_1 + 1, \text{MAX}_1) + \\
\max(1, \text{MIN}_2) > \text{NVERTEX}_{\text{INITIAL}} \Rightarrow \text{MIN}_1 = \text{MAX}_1
\]

(4.198)

**Proof.** The quantity \( \max(1, \text{MIN}_1) + \max(2, \text{MIN}_1 + 1, \text{MAX}_1) + \max(1, \text{MIN}_2) \) corresponds to the minimum number of variables needed for building two non-empty connected components of respective size \( \text{MIN}_1 \) and \( \text{MAX}_1 \) such that \( \text{MAX}_1 \) is strictly greater than \( \text{MIN}_1 \). If this quantity is greater than the total number of variables we have that \( \text{MIN}_1 = \text{MAX}_1 \). \( \square \)

**Proposition 137.**

\[
\text{vpartition} \land \text{consecutive}_\text{loops}_\text{are}_\text{connected} : \\
\text{MIN}_2 \notin \left[ \max \left( \frac{\text{NVERTEX}_{\text{INITIAL}} - \text{MAX}_1 - \text{MIN}_1 + 1}{2}, \right. \\
\text{NVERTEX}_{\text{INITIAL}} - \text{MAX}_1 - 1 \right] \\
\]

(4.199)

**Proof.** A value \( v \) is not a possible number of vertices for the smallest connected component of type 2 if the following two conditions hold:

- \( v + \text{MAX}_1 \) does not allow to cover all the vertices of the initial graph: we need at least one extra connected component of type 1 or 2.
- If we add an additional connected component of type 1 or 2 we exceed the number of vertices of the initial graph.

\( \square \)
4.3. GRAPH INVARIANTS

\[ \text{MAX}_NCC_2, \text{MIN}_NCC_2, \text{MIN}_NCC_1 \]

**Proposition 138.**

\[ \text{apartition} \land \text{arc_gen} = \text{PATH} : \]
\[ \max(2, \text{MIN}_NCC_2) + \max(3, \text{MIN}_NCC_2 + 1, \text{MAX}_NCC_2) + \]
\[ \max(2, \text{MIN}_NCC_1) - 2 > \text{NVERTEX}_{\text{INITIAL}} \Rightarrow \text{MIN}_NCC_2 = \text{MAX}_NCC_2 \]
\[ (4.200) \]

**Proof.** Similar to Proposition 135.

\[ \square \]

**Proposition 139.**

\[ \text{vpartition} \land \text{consecutive_loops_are_connected} : \]
\[ \max(1, \text{MIN}_NCC_2) + \max(2, \text{MIN}_NCC_2 + 1, \text{MAX}_NCC_2) + \]
\[ \max(1, \text{MIN}_NCC_1) > \text{NVERTEX}_{\text{INITIAL}} \Rightarrow \text{MIN}_NCC_2 = \text{MAX}_NCC_2 \]
\[ (4.201) \]

**Proof.** Similar to Proposition 136.

\[ \square \]

**Proposition 140.**

\[ \text{vpartition} \land \text{consecutive_loops_are_connected} : \]
\[ \text{MIN}_NCC_1 \notin \left[ \max \left( \frac{\text{NVERTEX}_{\text{INITIAL}} - \text{MAX}_NCC_2 - \text{MIN}_NCC_2 + 1}{2}, \right. \right. \]
\[ \left. \left. \left. \text{NVERTEX}_{\text{INITIAL}} - \text{MAX}_NCC_2 - 1 \right) \right) \right) \right) \]
\[ (4.202) \]

**Proof.** Similar to Proposition 137.

\[ \square \]

\[ \text{MAX}_NCC_1, \text{MIN}_NCC_1, \text{NVERTEX}_2 \]

**Proposition 141.**

\[ \text{vpartition} : \text{MIN}_NCC_1 = \text{MAX}_NCC_1 \land \text{MIN}_NCC_1 \mod 2 = 0 \Rightarrow \]
\[ \text{NVERTEX}_2 \mod 2 = \text{NVERTEX}_{\text{INITIAL}} \mod 2 \]
\[ (4.203) \]

**Proof.** If the number of vertices of the first graph is even then the number of vertices of the second graph has the same parity as the number of vertices of the initial graph (since a vertex of the initial graph belongs either to the first graph, either to the second graph (but not to both).

\[ \square \]

\[ \text{MAX}_NCC_2, \text{MIN}_NCC_2, \text{NVERTEX}_1 \]

**Proposition 142.**

\[ \text{vpartition} : \text{MIN}_NCC_2 = \text{MAX}_NCC_2 \land \text{MIN}_NCC_2 \mod 2 = 0 \Rightarrow \]
\[ \text{NVERTEX}_1 \mod 2 = \text{NVERTEX}_{\text{INITIAL}} \mod 2 \]
\[ (4.204) \]

**Proof.** Similar to Proposition 141.

\[ \square \]
Proposition 143.

\[ \text{apartition} \land \text{arc}_\text{gen} = \text{PATH} \land \text{NVERTEX}_{\text{INITIAL}} > 0 : \]
\[ \text{NCC}_1 = 1 \Leftrightarrow \text{MIN}_\text{NCC}_1 + \text{NARC}_2 = \text{NVERTEX}_{\text{INITIAL}} \]  \hspace{1cm} (4.205)

**Proof.** When \( \text{MIN}_\text{NCC}_1 + \text{NARC}_2 = \text{NVERTEX}_{\text{INITIAL}} \) there is no more room for an extra connected component for the first final graph. \( \Box \)

Proposition 144.

\[ \text{apartition} \land \text{arc}_\text{gen} = \text{PATH} \land \text{NVERTEX}_{\text{INITIAL}} > 0 : \]
\[ \text{NCC}_2 = 1 \Leftrightarrow \text{MIN}_\text{NCC}_2 + \text{NARC}_1 = \text{NVERTEX}_{\text{INITIAL}} \]  \hspace{1cm} (4.206)

**Proof.** Similar to Proposition 143. \( \Box \)
Graph invariants relating four parameters of two final graphs

Proposition 145.

\[
\text{apartition } \land \text{ arc_gen } = \text{ PATH} : \quad \max(2, \text{MIN}_1) + \max(2, \text{MAX}_1) + \max(2, \text{MIN}_2) - 2 > \quad N\text{VERTEX}_{\text{INITIAL}} \Rightarrow \text{NCC}_1 \leq 1
\] (4.207)

Proof. The quantity \(\max(2, \text{MIN}_1) + \max(2, \text{MAX}_1) + \max(2, \text{MIN}_2) - 2\) corresponds to the minimum number of variables needed for building two non-empty connected components of respective size \(\text{MIN}_1\) and \(\text{MAX}_1\). If this quantity is greater than the total number of variables we have that \(\text{NCC}_1 \leq 1\).

Proposition 146.

\[
\text{vpartition } \land \text{consecutive_loops_are_connected} : \quad \max(1, \text{MIN}_1) + \max(1, \text{MAX}_1) + \max(1, \text{MIN}_2) > \quad N\text{VERTEX}_{\text{INITIAL}} \Rightarrow \text{NCC}_1 \leq 1
\] (4.208)

Proof. The quantity \(\max(1, \text{MIN}_1) + \max(1, \text{MAX}_1) + \max(1, \text{MIN}_2)\) corresponds to the minimum number of variables needed for building two non-empty connected components of respective size \(\text{MIN}_1\) and \(\text{MAX}_1\). If this quantity is greater than the total number of variables we have that \(\text{NCC}_1 \leq 1\).

Proposition 147.

\[
\text{apartition } \land \text{arc_gen } = \text{ PATH} : \quad \max(2, \text{MIN}_2) + \max(2, \text{MAX}_2) + \max(2, \text{MIN}_1) - 2 > \quad N\text{VERTEX}_{\text{INITIAL}} \Rightarrow \text{NCC}_2 \leq 1
\] (4.209)

Proof. Similar to Proposition 145.

Proposition 148.

\[
\text{vpartition } \land \text{consecutive_loops_are_connected} : \quad \max(1, \text{MIN}_2) + \max(1, \text{MAX}_2) + \max(1, \text{MIN}_1) > \quad N\text{VERTEX}_{\text{INITIAL}} \Rightarrow \text{NCC}_2 \leq 1
\] (4.210)

Proof. Similar to Proposition 146.
Proposition 149.

\[
\text{vpartition} \land \text{consecutive_loops.are_connected}: \\
\text{MIN}_NCC_2 \not\in \left[ \left\lceil \frac{NVERTEX_2}{2} \right\rceil + 1, \\
NVERTEX_{\text{INITIAL}} - \text{MIN}_NCC_1 - \text{MAX}_NCC_1 - 1 \right]
\]

(4.211)

Proof. First, note that, when \( NCC_2 > 1 \), we have that \( \text{MIN}_NCC_2 \leq \left\lceil \frac{NVERTEX_2}{2} \right\rceil \).

Second, note that, when \( NCC_2 \leq 1 \), we have that \( \text{MIN}_NCC_2 \geq NVERTEX_{\text{INITIAL}} - \text{MIN}_NCC_1 - \text{MAX}_NCC_1 \). Since \( NCC_2 \) has to have at least one value the result follows.

Proposition 150.

\[
\text{vpartition} \land \text{consecutive_loops.are_connected}: \\
\text{MIN}_NCC_1 \not\in \left[ \left\lceil \frac{NVERTEX_1}{2} \right\rceil + 1, \\
NVERTEX_{\text{INITIAL}} - \text{MIN}_NCC_2 - \text{MAX}_NCC_2 - 1 \right]
\]

(4.212)

Proof. Similar to Proposition 149.

\( \square \)
Graph invariants relating five parameters of two final graphs
\[ \text{MAX}_1, \text{MAX}_2, \text{MIN}_1, \text{MIN}_2, \text{NCC} \]

**Proposition 151.**

\[
vpartition \land \text{consecutive loops are connected} : \\
\min_1 \cdot \max(0, \text{NCC}_1 - 1) + \max_1 + \\
\min_2 \cdot \max(0, \text{NCC}_1 - 2) + \max_2 \leq \text{NVERTEX}_{\text{initial}}. \\
\tag{4.213}
\]

**Proof.** The left-hand side of 151 corresponds to the minimum number of vertices of the two final graphs provided that we build the smallest possible connected components. \qed

**Proposition 152.**

\[
vpartition \land \text{consecutive loops are connected} : \\
\text{NCC}_1 \leq (\max_1 > 0) + \left\lfloor \frac{\alpha}{\beta} \right\rfloor + (\alpha \mod \beta \geq \max(1, \min_1)) \\
\{ \begin{align*}
\alpha &= \max(0, \text{NVERTEX}_{\text{initial}} - \max(1, \max_1) - \max(1, \max_2)), \\
\beta &= \max(1, \min_1) + \max(1, \min_2).
\end{align*} \tag{4.214}
\]

**Proof.** The maximum number of connected components is achieved by building non-empty groups as small as possible, except for two groups of respective size \(\max(1, \max_1)\) and \(\max(1, \max_2)\), which have to be built. \qed

**Proposition 153.**

\[
vpartition \land \text{consecutive loops are connected} : \\
\max_1 \cdot \max(0, \text{NCC}_1 - 1) + \min_1 + \\
\max_2 \cdot \text{NCC}_1 + \min_2 \geq \text{NVERTEX}_{\text{initial}}. \\
\tag{4.215}
\]

**Proof.** The left-hand side of 153 corresponds to the maximum number of vertices of the two final graphs provided that we build the largest possible connected components. \qed

**Proposition 154.**

\[
vpartition \land \text{consecutive loops are connected} : \\
\text{NCC}_1 \geq (\max_2 < \text{NVERTEX}_{\text{initial}}) + \left\lfloor \frac{\alpha}{\beta} \right\rfloor + (\alpha \mod \beta > \max_1) \\
\{ \begin{align*}
\alpha &= \max(0, \text{NVERTEX}_{\text{initial}} - \min_1 - \min_2), \\
\beta &= \max(1, \max_2) + \max(1, \max_1).
\end{align*} \tag{4.216}
\]

**Proof.** The minimum number of connected components is achieved by taking the groups as large as possible except for two groups of respective size \(\min_2 \) and \(\min_1\), which have to be built. \qed
Proposition 155.

\[ \text{vpartition} \land \text{consecutive\_loops\_are\_connected} : \]
\[ \text{MAX\_NCC}_2 \leq \max(\text{MIN\_NCC}_2, \text{NVERTEX}_{\text{initial}} - \alpha), \text{with} : \]
\[ \bullet \; \alpha = \text{MIN\_NCC}_1 \cdot \max(0, \text{NCC}_1 - 1) + \text{MAX\_NCC}_1 + \text{MIN\_NCC}_2 + \text{MAX\_NCC}_2 \cdot \max(0, \text{NCC}_1 - 3) \]

Proof. If \( NCC_1 \leq 1 \) we have that \( \text{MAX\_NCC}_2 \leq \text{MIN\_NCC}_2 \). Otherwise, when \( NCC_1 > 1 \), we have that \( \text{MIN\_NCC}_1 \cdot \max(0, \text{NCC}_1 - 1) + \text{MAX\_NCC}_1 + \text{MIN\_NCC}_2 + \text{MAX\_NCC}_2 + \text{MIN\_NCC}_2 \cdot \max(0, \text{NCC}_1 - 3) \leq \text{NVERTEX}_{\text{initial}} \).

\( NCC_1 - 3 \) comes from the fact that we build the minimum number of connected components in the second final graph (i.e., \( NCC_1 - 1 \) connected components) and that we have already built two connected components of respective size \( \text{MIN\_NCC}_2 \) and \( \text{MAX\_NCC}_2 \). By isolating \( \text{MAX\_NCC}_2 \) in the previous expression and by grouping the two inequalities the result follows.

Proposition 156.

\[ \text{apartition} \land \text{arc\_gen} = \text{PATH} \land \text{MIN\_NCC}_1 > 1 \land \text{MIN\_NCC}_2 > 1 : \]
\[ \text{NCC}_1 \leq (\text{MAX\_NCC}_1 > 0) + \left\lfloor \frac{\alpha}{\beta} \right\rfloor + ((\alpha \mod \beta) + 1 \geq \text{MIN\_NCC}_1), \text{with} : \]
\[ \begin{align*}
\bullet \; \alpha &= \max(0, \text{NVERTEX}_{\text{initial}} - \text{MAX\_NCC}_1 - \text{MAX\_NCC}_2 + 1), \\
\bullet \; \beta &= \text{MIN\_NCC}_1 + \text{MIN\_NCC}_2 - 2.
\end{align*} \]

\[ (4.218) \]

**Graph**

\[ G_1 \]

\[ \text{MAX\_NCC}_1 \]

\[ \text{MIN\_NCC}_1 \]

\[ G_2 \]

\[ \text{MAX\_NCC}_2 \]

\[ \text{MIN\_NCC}_2 \]

**Initial graph**

\[ \text{too small connected component} \]

\[ \text{Figure 4.9: Illustration of Proposition 156. Configuration achieving the maximum number of connected components for } G_1 \text{ according to the size of the smallest and largest connected components of } G_1 \text{ and } G_2 \text{ and to an initial number of vertices (MAX\_NCC}_1 = 4, \text{MAX\_NCC}_2 = 5, \text{MIN\_NCC}_1 = 3, \text{MIN\_NCC}_2 = 4, \text{NVERTEX}_{\text{initial}} = 14, \alpha = \max(0, 14 - 4 - 5 + 1) = 6, \beta = 6, \text{MIN\_NCC}_1 + \text{MIN\_NCC}_2 - 2 = 5, NCC_1 = (4 > 0) + \left\lfloor \frac{6}{2} \right\rfloor + \left( (6 \mod 5) + 1 \right) \geq 3 = 2) \text{; since the two rightmost vertices of graph } G_1 \text{ correspond to a too small connected component, they will have to be dispatched in the other connected components of graph } G_1 \text{.} \]

**Proof.** The maximum number of connected components of \( G_1 \) is achieved by:

- Building a first connected component of \( G_1 \) involving \( \text{MAX\_NCC}_1 \) vertices,
- Building a first connected component of \( G_2 \) involving \( \text{MAX\_NCC}_2 \) vertices,
4.3. GRAPH INVARIANTS 

• Building alternatively a connected component of $G_1$ and a connected component of $G_2$ involving respectively $\text{MIN}_N\text{CC}_1$ and $\text{MIN}_N\text{CC}_2$ vertices,

• Finally, if this is possible, building a connected component of $G_1$ involving $\text{MIN}_N\text{CC}_1$ vertices.

Proposition 157.

\begin{align}
\text{apartition} \wedge \text{arc.gen} &= \text{PATH} \wedge \text{MIN}_N\text{CC}_1 > 1 \wedge \text{MIN}_N\text{CC}_2 > 1 : \\
\text{NCC}_1 &\geq (\text{MIN}_N\text{CC}_1 > 0) + \left\lfloor \frac{\alpha}{\beta} \right\rfloor + ((\alpha \mod \beta) + 1 > \text{MAX}_N\text{CC}_2), \text{ with} : \\
\{ &\alpha = \max(0, \text{NVERTEX}_{\text{INITIAL}} - \text{MIN}_N\text{CC}_1 - \text{MIN}_N\text{CC}_2 + 1), \\
&\beta = \text{MAX}_N\text{CC}_1 + \text{MAX}_N\text{CC}_2 - 2. \\
\}
\end{align}

(4.219)

Figure 4.10: Illustration of Proposition 157. Configuration achieving the minimum number of connected components for $G_1$ according to the size of the smallest and largest connected components of $G_1$ and $G_2$ and to an initial number of vertices ($\text{MAX}_N\text{CC}_1 = 4, \text{MAX}_N\text{CC}_2 = 5, \text{MIN}_N\text{CC}_1 = 3, \text{MIN}_N\text{CC}_2 = 4, \text{NVERTEX}_{\text{INITIAL}} = 18, \alpha = \max(0, 18 - 3 - 4 + 1) = 12, \beta = \max(2, 4 + 5 - 2) = 7, \text{NCC}_1 = (3 > 0) + \left\lfloor \frac{12}{7} \right\rfloor + ((12 \mod 7) + 1) > 5) = 3$)

Proof. The minimum number of connected components of $G_1$ is achieved by:

• Building a first connected component of $G_2$ involving $\text{MIN}_N\text{CC}_2$ vertices,

• Building a first connected component of $G_1$ involving $\text{MIN}_N\text{CC}_1$ vertices,

• Building alternatively a connected component of $G_2$ and a connected component of $G_1$ involving respectively $\text{MAX}_N\text{CC}_2$ and $\text{MAX}_N\text{CC}_1$ vertices,

• Finally, if this is possible, building a connected component of $G_2$ involving $\text{MAX}_N\text{CC}_2$ vertices and a connected component of $G_1$ with the remaining vertices. Note that these remaining vertices cannot be incorporated in the connected components previously built.
MAX\_NCC\_1, MAX\_NCC\_2, MIN\_NCC\_1, MIN\_NCC\_2, NCC\_2

Proposition 158.

\(vpartition \land consecutive\_loops\_are\_connected:\)

\[
\begin{align*}
\text{MIN}\_\text{NCC}\_2 \cdot \max(0, \text{NCC}\_2 - 1) + \text{MAX}\_\text{NCC}\_2 + \\
\text{MIN}\_\text{NCC}\_1 \cdot \max(0, \text{NCC}\_2 - 2) + \text{MAX}\_\text{NCC}\_1 \leq N\text{VERTEX}_{\text{INITIAL}}
\end{align*}
\] (4.220)

**Proof.** Similar to Proposition 151.

Proposition 159.

\(vpartition \land consecutive\_loops\_are\_connected:\)

\[

**Proof.** Similar to Proposition 155.
4.3. GRAPH INVARIANTS

Proposition 163.

\[ \text{apartition} \land \text{arc_gen} = \text{PATH} \land \text{MIN}_{\text{NCC}}_1 > 1 \land \text{MIN}_{\text{NCC}}_2 > 1 : \]

\[ \text{NCC}_2 \leq (\text{MAX}_{\text{NCC}}_2 > 0) + \left\lfloor \frac{\alpha}{\beta} \right\rfloor + ((\alpha \mod \beta) + 1 \geq \text{MIN}_{\text{NCC}}_2), \text{ with:} \]

\[ \begin{cases} 
\alpha = \max(0, \text{NVERTEX}_{\text{INITIAL}} - \text{MAX}_{\text{NCC}}_1 - \text{MAX}_{\text{NCC}}_2 + 1), \\
\beta = \text{MIN}_{\text{NCC}}_1 + \text{MIN}_{\text{NCC}}_2 - 2. 
\end{cases} \] (4.225)

Proof. Similar to Proposition 156.

Proposition 164.

\[ \text{apartition} \land \text{arc_gen} = \text{PATH} \land \text{MIN}_{\text{NCC}}_1 > 1 \land \text{MIN}_{\text{NCC}}_2 > 1 : \]

\[ \text{NCC}_2 \geq (\text{MIN}_{\text{NCC}}_2 > 0) + \left\lfloor \frac{\alpha}{\beta} \right\rfloor + ((\alpha \mod \beta) + 1 > \text{MAX}_{\text{NCC}}_1), \text{ with:} \]

\[ \begin{cases} 
\alpha = \max(0, \text{NVERTEX}_{\text{INITIAL}} - \text{MIN}_{\text{NCC}}_1 - \text{MIN}_{\text{NCC}}_2 + 1), \\
\beta = \text{MAX}_{\text{NCC}}_1 + \text{MAX}_{\text{NCC}}_2 - 2. 
\end{cases} \] (4.226)

Proof. Similar to Proposition 157.
Graph invariants relating six parameters of two final graphs

\[ \text{MAX}_1, \text{MAX}_2, \text{MIN}_1, \text{MIN}_2, \text{NCC}_1, \text{NCC}_2 \]

**Proposition 165.**

\[
\text{apartition} \land \text{arc} \land \text{gen} = \text{PATH} \land \text{NVERTEX}_\text{INITIAL} > 0 : \\
\alpha \cdot \text{MIN}_1 + \text{MAX}_1 + \\
\beta \cdot \text{MIN}_2 + \text{MAX}_2 \leq \text{NVERTEX}_\text{INITIAL} + \text{NCC}_1 + \text{NCC}_2 - 1, \text{ with}:
\]

- \( \alpha = \max(0, \text{NCC}_1 - 1) \),
- \( \beta = \max(0, \text{NCC}_2 - 1) \).

(4.227)

**Proof.** Let \( \text{CC}(G_1) = \{ CC_1^a : a \in [\text{NCC}_1] \} \) and \( \text{CC}(G_2) = \{ CC_2^a : a \in [\text{NCC}_2] \} \) be respectively the set of connected components of the first and the second final graphs. Since the initial graph is a path, and since each arc of the initial graph belongs to the first or to the second final graphs (but not to both), there exists \( (A_i)_{i \in [\text{NCC}_1 + \text{NCC}_2]} \) and there exists \( j \in [2] \) such that \( A_i \in \text{CC}(G_{1+(j \mod 2)}) \), for \( i \mod 2 = 0 \) and \( A_i \in \text{CC}(G_{1+((j+1) \mod 2)}) \) for \( i \mod 2 = 1 \) and \( A_i \cap A_{i+1} \neq \emptyset \) for every well defined \( i \).

By inclusion-exclusion principle, since \( A_i \cap A_j = \emptyset \) whenever \( j \neq i + 1 \), we obtain \( \text{NVERTEX}_\text{INITIAL} = \Sigma_{a \in [\text{NCC}_1]} |CC_1^a| + \Sigma_{a \in [\text{NCC}_2]} |CC_2^a| - \Sigma_{a \in [\text{NCC}_1 + \text{NCC}_2]} |A_i \cap A_{i+1}|. \) Since \( |A_i \cap A_{i+1}| \) is equal to 1 for every well defined \( i \), we obtain \( \Sigma_{a \in [\text{NCC}_1]} |CC_1^a| + \Sigma_{a \in [\text{NCC}_2]} |CC_2^a| = \text{NVERTEX}_\text{INITIAL} + \text{NCC}_1 + \text{NCC}_2 - 1. \) Since \( \alpha \cdot \text{MIN}_1 + \text{MAX}_1 + \beta \cdot \text{MIN}_2 + \text{MAX}_2 \leq \Sigma_{a \in [\text{NCC}_1]} |CC_1^a| + \Sigma_{a \in [\text{NCC}_2]} |CC_2^a| \) the result follows. \( \square \)

**Proposition 166.**

\[
\text{apartition} \land \text{arc} \land \text{gen} = \text{PATH} \land \text{NVERTEX}_\text{INITIAL} > 0 : \\
\alpha \cdot \text{MAX}_1 + \text{MIN}_1 + \\
\beta \cdot \text{MAX}_2 + \text{MIN}_2 \geq \text{NVERTEX}_\text{INITIAL} + \text{NCC}_1 + \text{NCC}_2 - 1, \text{ with}:
\]

- \( \alpha = \max(0, \text{NCC}_1 - 1) \),
- \( \beta = \max(0, \text{NCC}_2 - 1) \).

(4.228)

**Proof.** Similar to Proposition 165. \( \square \)
4.4 Functional dependency invariants

This section provides invariants relating functionally dependent constraints arguments.

4.4.1 Functional dependency invariants involving two constraints

Proposition 167. Given the constraints
- \textsc{inflexion}(\textsc{ninf}, \textsc{variables}),
- \textsc{nvalue}(\textsc{nval}, \textsc{variables}):

\[ \textsc{nval} = 1 \Rightarrow \textsc{ninf} = 0 \quad (4.229) \]

\textit{Proof.} Since a single value leads to a plateau.

Proposition 168. Given the constraints
- \textsc{length\_first\_sequence}(\textsc{len}, \textsc{variables}),
- \textsc{peak}(\textsc{p}, \textsc{variables}):

\[ 2 \cdot \textsc{p} \leq |\textsc{variables}| - \textsc{len} \quad (4.230) \]

\textit{Proof.} Beside a first sequence with a small value, we alternate between large and small values in order to maximise the number of peaks.

Proposition 169. Given the constraints
- \textsc{length\_first\_sequence}(\textsc{len}, \textsc{variables}),
- \textsc{valley}(\textsc{v}, \textsc{variables}):

\[ 2 \cdot \textsc{v} \leq |\textsc{variables}| - \textsc{len} \quad (4.231) \]

\textit{Proof.} Beside a first sequence with a large value, we alternate between small and large values in order to maximise the number of valleys.

Proposition 170. Given the constraints
- \textsc{length\_last\_sequence}(\textsc{len}, \textsc{variables}),
- \textsc{peak}(\textsc{p}, \textsc{variables}):

\[ 2 \cdot \textsc{p} \leq |\textsc{variables}| - \textsc{len} \quad (4.232) \]

\textit{Proof.} Beside a last sequence with a small value, we alternate between large and small values in order to maximise the number of peaks.

Proposition 171. Given the constraints
- \textsc{length\_last\_sequence}(\textsc{len}, \textsc{variables}),
- \textsc{valley}(\textsc{v}, \textsc{variables}):

\[ 2 \cdot \textsc{v} \leq |\textsc{variables}| - \textsc{len} \quad (4.233) \]

\textit{Proof.} Beside a last sequence with a large value, we alternate between small and large values in order to maximise the number of valleys.

Proposition 172. Given the constraints
- \textsc{longest\_decreasing\_sequence}(\textsc{l}, \textsc{variables}),
• \texttt{\texttt{MAX\_DECREASING\_SLOPE}(MAX, VARIABLES)}:
  \[ L \geq \text{MAX} \quad (4.234) \]

\textit{Proof.} By definition of the \texttt{LONGEST\_DECREASING\_SEQUENCE} and \texttt{MAX\_DECREASING\_SLOPE} constraints. \hfill \square

\textbf{Proposition 173.} Given the constraints

\begin{itemize}
  \item \texttt{\texttt{LONGEST\_INCREASING\_SEQUENCE}(L, VARIABLES)},
  \item \texttt{MAX\_INCREASING\_SLOPE}(MAX, VARIABLES):
    \[ L \geq \text{MAX} \quad (4.235) \]
\end{itemize}

\textit{Proof.} By definition of the \texttt{LONGEST\_INCREASING\_SEQUENCE} and \texttt{MAX\_INCREASING\_SLOPE} constraints. \hfill \square

\textbf{Proposition 174.} Given the constraints

\begin{itemize}
  \item \texttt{\texttt{MAX\_DECREASING\_SLOPE}(MAX, VARIABLES)},
  \item \texttt{MIN\_DECREASING\_SLOPE}(MIN, VARIABLES):
    \[ \text{MAX} \geq \text{MIN} \quad (4.236) \]
\end{itemize}

\textit{Proof.} By definition of the \texttt{MAX\_DECREASING\_SLOPE} and \texttt{MIN\_DECREASING\_SLOPE} constraints. \hfill \square

\textbf{Proposition 175.} Given the constraints

\begin{itemize}
  \item \texttt{MAX\_INCREASING\_SLOPE}(MAX, VARIABLES),
  \item \texttt{MIN\_INCREASING\_SLOPE}(MIN, VARIABLES):
    \[ \text{MAX} \geq \text{MIN} \quad (4.237) \]
\end{itemize}

\textit{Proof.} By definition of the \texttt{MAX\_INCREASING\_SLOPE} and \texttt{MIN\_INCREASING\_SLOPE} constraints. \hfill \square

\textbf{Proposition 176.} Given the constraints

\begin{itemize}
  \item \texttt{MAXIMUM}(MAX, VARIABLES),
  \item \texttt{MINIMUM}(MIN, VARIABLES):
    \[ \text{MAX} \geq \text{MIN} \quad (4.238) \]
\end{itemize}

\textit{Proof.} By definition of the \texttt{MAXIMUM} and the \texttt{MINIMUM} constraints. \hfill \square

\textbf{Proposition 177.} Given the constraints

\begin{itemize}
  \item \texttt{MAXIMUM}(MAX, VARIABLES),
  \item \texttt{SUM\_CTR}(VARIABLES, =, SUM):
    \[ \text{SUM} \leq |\text{VARIABLES}| \cdot \text{MAX} \quad (4.239) \]
\end{itemize}

\textit{Proof.} By definition of the \texttt{MAXIMUM} and \texttt{SUM\_CTR} constraints. \hfill \square

\textbf{Proposition 178.} Given the constraints

\begin{itemize}
  \item \texttt{MINIMUM}(MIN, VARIABLES),
  \item \texttt{SUM\_CTR}(VARIABLES, =, SUM):
\end{itemize}
4.4. FUNCTIONAL DEPENDENCY INVARIANTS

\[ \text{SUM} \geq |\text{VARIABLES}| \cdot \text{MIN} \]  \hspace{1cm} (4.240)

**Proof.** By definition of the MINIMUM and SUM_CTR constraints.

**Proposition 179.** Given the constraints

- \( \text{MIN}_W \text{IDTH}_\text{PEAK}(\text{MIN}_W \text{IDTH}, \text{VARIABLES}) \),
- \( \text{PEAK}(P, \text{VARIABLES}) \):

\[ P \cdot \text{MIN}_W \text{IDTH} \leq |\text{VARIABLES}| \]  \hspace{1cm} (4.241)

**Proof.** Cumulated minimum width of the different peaks cannot exceed size of sequence.

**Proposition 180.** Given the constraints

- \( \text{MIN}_W \text{IDTH}_\text{PEAK}(\text{MIN}_W \text{IDTH}, \text{VARIABLES}) \),
- \( \text{PEAK}(P, \text{VARIABLES}) \):

The automaton depicted by Figure 4.11 provides a necessary condition.

\[
\begin{align*}
\forall i \in [1, |\text{VARIABLES}| - 1], \quad & \text{cond} \quad \text{VAR}_i \geq \text{VAR}_{i+1}, \\
& \{\text{dec}\} \\
\forall i \in [1, |\text{VARIABLES}| - 1], \quad & \text{cond} \quad \text{VAR}_i < \text{VAR}_{i+1}, \\
& \{\text{cond}, S \leftarrow S + 1, F \leftarrow i\} \\
\forall i \in [1, |\text{VARIABLES}| - 1], \quad & \text{cond} \quad \text{VAR}_i > \text{VAR}_{i+1}, \\
& \{\text{cond}\} \\
\forall i \in [1, |\text{VARIABLES}| - 1], \quad & \text{cond} \quad \text{VAR}_i \leq \text{VAR}_{i+1}, \\
& \{\text{cond}\}
\end{align*}
\]

Figure 4.11: Automaton for a redundant constraint between the \( \text{PEAK}(P, \text{VARIABLES}) \) and the \( \text{MIN}_W \text{IDTH}_\text{PEAK}(\text{MIN}_W \text{IDTH}, \text{VARIABLES}) \) constraints when \( P > 0 \) and \( \text{MIN}_W \text{IDTH} > 0 \), where \text{cond} is the condition \(|\text{VARIABLES}| - i > \max(0, \max(\text{MIN}_W \text{IDTH} + 1) + \max(P - \max(S - 1, 0), 0) \geq 1) \cdot (\text{MIN}_W \text{IDTH} - \max(i - F, 0))\), and where \( i, S \) and \( F \) respectively stand for the index of the current pairs \((i \in [1, |\text{VARIABLES}| - 1])\), the number of start of potential peaks already encountered, the position of the start of the last potential peak encountered; the quantity \( \max(S - 1, 0) \) denotes the number of peaks already encountered, while the quantity \( \max(P - \max(S - 1, 0), 0) \) denotes the minimum number of peaks that remain to done from position \( i \).

**Proof.** The condition associated with each transition of the automaton checks that there is enough space between the current position and the end of the sequence to place the remaining minimum number of required peaks.

**Proposition 181.** Given the constraints

- \( \text{MIN}_W \text{IDTH}_\text{VALLEY}(\text{MIN}_W \text{IDTH}, \text{VARIABLES}) \),
- \( \text{VALLEY}(V, \text{VARIABLES}) \):

\[ V \cdot \text{MIN}_W \text{IDTH} \leq |\text{VARIABLES}| \]  \hspace{1cm} (4.242)

**Proof.** Cumulated minimum width of the different valleys cannot exceed size of sequence.
Proposition 182. Given the constraints
- \textsc{min-width-valley}(\textsc{min-width}, \textsc{variables}),
- \textsc{valley}(\textit{V}, \textsc{variables})

The automaton depicted by Figure 4.12 provides a necessary condition.

\begin{itemize}
  \item \texttt{inc}\{cond\} \quad \texttt{VAR}_i \leq \texttt{VAR}_{i+1}, \quad \texttt{cond} \quad \texttt{VAR}_i \geq \texttt{VAR}_{i+1}, \quad \texttt{cond}, \texttt{S} \leftarrow \texttt{S} + 1, \texttt{F} \leftarrow \texttt{i}
  \item \texttt{dec}\{cond\} \quad \texttt{VAR}_i < \texttt{VAR}_{i+1}, \quad \texttt{cond} \quad \texttt{VAR}_i \geq \texttt{VAR}_{i+1}, \quad \texttt{cond}
\end{itemize}

Figure 4.12: Automaton for a redundant constraint between the \textsc{valley}(\textit{V}, \textsc{variables}) and the \textsc{min-width-valley}(\textsc{min-width}, \textsc{variables}) constraints when \( \textit{V} > 0 \) and \textsc{min-width} > 0, where \texttt{cond} is the condition \(|\textsc{variables}| - i > \max(0, \max(\textit{V} - \max(\textit{S} - 1, 0), 0) - 1) \cdot \textsc{min-width} + (\max(\textit{V} - \max(\textit{S} - 1, 0), 0) \geq 1) \cdot (\textsc{min-width} - \max(i - \text{F}, 0))\), and where \( i, S \) and \( F \) respectively stand for the index of the current pairs \( i \in [1, |\textsc{variables}| - 1] \), the number of start of potential valleys already encountered, the position of the start of the last potential valley encountered; the quantity \( \max(S - 1, 0) \) denotes the number of valleys already encountered, while the quantity \( \max(V - \max(S - 1, 0), 0) \) denotes the minimum number of valleys that remain to done from position \( i \).

\textbf{Proof.} The condition associated with each transition of the automaton checks that there is enough space between the current position and the end of the sequence to place the remaining minimum number of required valleys.

Proposition 183. Given the constraints
- \textsc{nvalue}(\textsc{nval}, \textsc{variables}),
- \textsc{nvisible-from-end}(\textsc{n}, \textsc{variables})

\textsc{nval} \geq \textsc{n} \quad (4.243)

\textbf{Proof.} Since stairs visible from the end are located at different altitudes.

Proposition 184. Given the constraints
- \textsc{nvalue}(\textsc{nval}, \textsc{variables}),
- \textsc{nvisible-from-start}(\textsc{n}, \textsc{variables})

\textsc{nval} \geq \textsc{n} \quad (4.244)

\textbf{Proof.} Since stairs visible from the start are located at different altitudes.

Proposition 185. Given the constraints
- \textsc{peak}(\textsc{p}, \textsc{variables}),
4.4. FUNCTIONAL DEPENDENCY INVARIANTS

- **VALLEY**\((V, \text{VARIABLES})\):
  \[ |P - V| \leq 1 \] (4.245)

**Proof.** Since peaks and valleys can only alternate. \qed

**Proposition 186.** Given the constraints
- **PEAK**\((P, \text{VARIABLES})\),
- **VALLEY**\((V, \text{VARIABLES})\),

with \(P > V\), the automaton depicted by Figure 4.13 provides a necessary condition.

![Figure 4.13: Automaton for a redundant constraint for the conjunction PEAK(P, VARIABLES) \& VALLEY(V, VARIABLES) \& P > V (we have both to start with a peak and to finish with a peak)](image)

**Proof.** Since peaks and valleys can only alternate and since having more peaks than valleys enforces to start and end on a peak. \qed

**Proposition 187.** Given the constraints
- **PEAK**\((P, \text{VARIABLES})\),
- **VALLEY**\((V, \text{VARIABLES})\),

with \(V > P\) the automaton depicted by Figure 4.14 provides a necessary condition.

![Figure 4.14: Automaton for a redundant constraint for the conjunction VALLEY(V, VARIABLES) \& PEAK(P, VARIABLES) \& V > P (we have both to start with a valley and to finish with a valley)](image)
Proof. Since valleys and peaks can only alternate and since having more valleys than peaks enforces to start and end on a valley.

4.4.2 Functional dependency invariants involving three constraints

Proposition 188. Given the constraints

- \textsc{inflexion}(I, \textsc{variables}),
- \textsc{peak}(P, \textsc{variables}),
- \textsc{valley}(V, \textsc{variables}):

\[ I = P + V \] (4.246)

Proof. By definition of the \textsc{inflexion}, \textsc{peak} and \textsc{valley} constraints.

Proposition 189. Given the constraints

- \textsc{length}_\text{first}_\text{sequence}(\textsc{len}_\text{first}, \textsc{variables}),
- \textsc{length}_\text{last}_\text{sequence}(\textsc{len}_\text{last}, \textsc{variables}),
- \textsc{nvalue}(\textsc{nval}, \textsc{variables}):

\[ \textsc{nval} > 1 \Rightarrow \textsc{len}_\text{first} + \textsc{len}_\text{last} + \textsc{nval} - 2 \leq |\textsc{variables}| \] (4.247)

Proof. Since we have at least two distinct values the first and last sequences do not overlap. Since we have at least \textsc{nval} distinct values we have at least \textsc{nval} – 2 additional values excluding the first and last sequences, which use at most two distinct values.

Proposition 190. Given the constraints

- \textsc{longest}_\text{decreasing}_\text{sequence}(L, \textsc{variables}),
- \textsc{maximum}(\textsc{max}, \textsc{variables}),
- \textsc{minimum}(\textsc{min}, \textsc{variables}):

\[ \textsc{max} - \textsc{min} \geq L \] (4.248)

Proof. By definition of the \textsc{longest}_\text{decreasing}_\text{sequence} constraint.

Proposition 191. Given the constraints

- \textsc{longest}_\text{increasing}_\text{sequence}(L, \textsc{variables}),
- \textsc{maximum}(\textsc{max}, \textsc{variables}),
- \textsc{minimum}(\textsc{min}, \textsc{variables}):

\[ \textsc{max} - \textsc{min} \geq L \] (4.249)

Proof. By definition of the \textsc{longest}_\text{increasing}_\text{sequence} constraint.

Proposition 192. Given the constraints

- \textsc{maximum}(\textsc{max}, \textsc{variables}),
- \textsc{minimum}(\textsc{min}, \textsc{variables}),
- \textsc{nvalue}(\textsc{nval}, \textsc{variables}):

\[ \textsc{nval} \leq \textsc{max} - \textsc{min} + 1 \] (4.250)
4.4. FUNCTIONAL DEPENDENCY INVARIANTS

Proof. Since taking all values between $\text{MIN}$ and $\text{MAX}$ gives the maximum number of distinct values.

Proposition 193. Given the constraints
- $\text{MAXIMUM}$(MAX, VARIABLES),
- $\text{MINIMUM}$(MIN, VARIABLES),
- $\text{NVALUE}$(NVAL, VARIABLES):
  \[
  \text{MAX} > \text{MIN} \Rightarrow \text{NVAL} > 1 
  \] (4.251)

Proof. Since at least two distinct values if $\text{MIN}$ and $\text{MAX}$ are distinct.

Proposition 194. Given the constraints
- $\text{MAXIMUM}$(MAX, VARIABLES),
- $\text{MINIMUM}$(MIN, VARIABLES),
- $\text{SUM}_\text{CTR}$(VARIABLES, $=\cdot$, SUM):
  \[
  \text{SUM} \geq (|\text{VARIABLES}| - 1) \cdot \text{MIN} + \text{MAX} 
  \] (4.252)

Proof. Since also has to use the maximum value at least once in the sum.

Proposition 195. Given the constraints
- $\text{MAXIMUM}$(MAX, VARIABLES),
- $\text{MINIMUM}$(MIN, VARIABLES),
- $\text{SUM}_\text{CTR}$(VARIABLES, $=\cdot$, SUM):
  \[
  \text{SUM} \leq (|\text{VARIABLES}| - 1) \cdot \text{MAX} + \text{MIN} 
  \] (4.253)

Proof. Since also has to use the minimum value at least once in the sum.

4.4.3 Functional dependency invariants involving four constraints

Proposition 196. Given the constraints
- $\text{LENGTH}_\text{FIRST}$(LEN_FIRST, VARIABLES),
- $\text{LENGTH}_\text{LAST}$(LEN_LAST, VARIABLES),
- $\text{NVALUE}$(NVAL, VARIABLES),
- $\text{PEAK}$(P, VARIABLES):
  \[
  \text{NVAL} > 1 \Rightarrow 2 \cdot P \leq |\text{VARIABLES}| - \max(1, \text{LEN}_\text{FIRST}) - \max(1, \text{LEN}_\text{LAST}) + 1 
  \] (4.254)

Proof. Beside the first and the last sequence with a small value, we alternate between large and small values.

Proposition 197. Given the constraints
- $\text{LENGTH}_\text{FIRST}$(LEN_FIRST, VARIABLES),
- $\text{LENGTH}_\text{LAST}$(LEN_LAST, VARIABLES),
- $\text{NVALUE}$(NVAL, VARIABLES),
- $\text{VALLEY}$(V, VARIABLES):
  \[
  \text{NVAL} > 1 \Rightarrow 2 \cdot V \leq |\text{VARIABLES}| - \max(1, \text{LEN}_\text{FIRST}) - \max(1, \text{LEN}_\text{LAST}) + 1 
  \] (4.255)

Proof. Beside the first and the last sequence with a large value, we alternate between small and large values.
4.5 The electronic version of the catalogue

4.5.1 Prolog facts describing a constraint

An electronic version of the catalogue containing every global constraint of the catalogue is given in Appendix B. In addition the entry “Utilities” contains a set of shared utilities used for evaluating the constraints. This electronic version was used for generating the \LaTeX file of this catalogue, the figures associated with the graph-based description and a filtering algorithm for some of the constraints that use the automaton-based description. Within the electronic version, each constraint is described in terms of meta-data. A typical entry is:

```prolog
ctr_date(minimum, ['20000128','20030820','20040530', '20041230','20060811','20090416']).
ctr_origin(minimum, '\\index{CHIP|indexuse}CHIP', []).
ctr_arguments(minimum, ['MIN'-dvar, 'VARIABLES'-collection{var-dvar}]).
ctr_exchangeable(minimum, [items('VARIABLES',all), vals(['VARIABLES' 'var'],int,\=,all,in), translate(['MIN','VARIABLES' 'var'])]).
ctr_synonyms(minimum, []).
ctr_restrictions(minimum, [size('VARIABLES')\>0, required('VARIABLES',var)]). 
ctr_typical(minimum, [size('VARIABLES') > 1, range('VARIABLES' 'var') > 1]).
ctr_pure_functional_dependency(minimum, []).
ctr_functional_dependency(minimum, 1, [2]).
ctr_aggregate(minimum, [], [min, union]).
ctr_graph(minimum, ['VARIABLES'], 2, ['CLIQUE']\>collection{variables1,variables2}),
[variables1'key=variables2'key #\ variables1'var<variables2'var],
['ORDER'(0,'MAXINT',var)'=MIN'], [])
```
4.5. THE ELECTRONIC VERSION OF THE CATALOGUE

and consists of the following Prolog facts, where CONSTRAINT_NAME is the name of the constraint under consideration. The facts are organised in the following 20 items:
• Items 1, 2, 3, 4, 16 and 17 provide general information about a global constraint,
• Items 5, 6, 7 and 8 describe the arguments of a global constraint.
• Items 9 and 10 give properties of the arguments of a global constraint, e.g. functional dependency, contractibility.
• Item 11 describes symmetries of a global constraint, i.e. list of mappings (e.g., permutation of arguments) that preserve the solutions to a global constraint.
• Items 12 and 13 describes the meaning of a global constraint in terms of a graph-based representation.
• Item 14 provides one or several ground instances which hold.
• Item 18 gives the list of available evaluators of a global constraint.
• Item 19 provides the number of solutions to the constraint under various assumptions on the number of variables and on their initial domains.
• Item 20 describes the meaning of a global constraint in terms of a set of first order logic formulae.

Items 1, 2, 6 and 14 are mandatory, while all other items are optional. We now give the different items:

1. ctr_date( CONSTRAINT_NAME, LIST_OFDATES_OF_MODIFICATIONS )
   • LIST_OFDATES_OF_MODIFICATIONS is a list of dates when the description of the constraint was modified.

2. ctr_origin( CONSTRAINT_NAME, STRING, LIST_OFCONSTRAINTS_NAMES )
   • STRING is a string denoting the origin of the constraint. LIST_OFCONSTRAINTS_NAMES is a possibly empty list of constraint names related to the origin of the constraint.

3. ctr_usual_name( CONSTRAINT_NAME, USUAL_NAME )
   • When, for some reason, the constraint name used in the catalogue does not correspond to the usual name of the constraint, USUAL_NAME provides the usual name of the constraint. This stems from the fact that each entry of the catalogue should have a distinct name. This is the case, for example, for the STRETCH_PATH and the STRETCH_CIRCUIT constraints which are both usually called STRETCH.

4. ctr_synonyms( CONSTRAINT_NAME, LIST_OFSYNONYMS )
   • LIST_OFSYNONYMS is a list of synonyms for the constraint. This stems from the fact that, quite often, different authors use a different name for the same constraint. This is the case, for example, for the ALLDIFFERENT and the SYMMETRIC_ALLDIFFERENT constraints.
5. **ctr.types**( CONSTRAINT_NAME, LIST_OF_TYPES_DECLARATIONS )

- LIST_OF_TYPES_DECLARATIONS is a list of elements of the form name-type, where name is the name of a new type and type the type itself (usually a collection). Basic and compound data types were respectively introduced in sections 2.2.1 and 2.2.2 on page 14. This field is only used when we need to declare a new type that will be used for specifying the type of the arguments of the constraint. This is the case, for example, when one argument of the constraint is a collection for which the type of one attribute is also a collection. This is the case, for example, for the **DIFFN** constraint where the unique argument ORTHOTOPE is a collection of ORTHOTOPE; ORTHOTOPE refers to a new type declared in LIST_OF_TYPES_DECLARATIONS.

6. **ctr.arguments**( CONSTRAINT_NAME, LIST_OF_ARGUMENTS_DECLARATIONS )

- LIST_OF_ARGUMENTS_DECLARATIONS is a list of elements of the form arg-type, where arg is the name of an argument of the constraint and type the type of the argument. Basic and compound data types were respectively introduced in sections 2.2.1 and 2.2.2 on page 14.

7. **ctr.restrictions**( CONSTRAINT_NAME, LIST_OF_RESTRICTIONS )

- LIST_OF_RESTRICTIONS is a list of restrictions on the different arguments of the constraint. Possible restrictions were described in Section 2.2.3 on page 17.

8. **ctr.typical**( CONSTRAINT_NAME, LIST_OF_RESTRICTIONS )

- LIST_OF_RESTRICTIONS is a list of typical restrictions on the different arguments of the constraint, i.e. even though these restrictions are not mandatory they usually hold. Possible restrictions were described in Section 2.2.3 on page 17.

9. **ctr.pure_functional_dependency**( CONSTRAINT_NAME, LIST_OF_RESTRICTIONS )

- Indicate that, under the assumption that all restrictions described by LIST_OF_RESTRICTIONS hold, at least one of the arguments of the constraint is functionally determined by the other arguments. Possible restrictions were described in Section 2.2.3 on page 17. Which argument ARG is determined by which subset of arguments LISTARGS is described by the fact ctr_functional_dependency( CONSTRAINT_NAME, ARG, LISTARGS ) where arguments are denoted by their positions within the constraint.

10. **ctr.aggregate**( CONSTRAINT_NAME, LIST_OF_RESTRICTIONS, ARGAgregar )

Denotes that, given two instances of the constraint that both satisfy all restrictions described by LIST_OF_RESTRICTIONS, we can combine (i.e., aggregate) these two instances in order to obtain an implied constraint, which has the same name as the first two constraints. We use ARGAgregar in order to obtain the arguments of the implied constraint as described in the keyword Aggregate.

11. **ctr.exchangeable**( CONSTRAINT_NAME, LIST_OF_SYMMETRIES )

- LIST_OF_SYMMETRIES is a list of mappings preserving the solutions to the constraint. Possible mappings were described in Section 2.2.5 on page 27.
12. ctr_derived_collections(CONSTRAINT_NAME, LIST_OF_DERIVED_COLLECTIONS)

- LIST_OF_DERIVED_COLLECTIONS is a list of derived collections. Derived collections are collections that are computed from the arguments of the constraint and are used in the graph-based description. Derived collections were described in Section 2.3.2 on page 51.

13. ctr_graph(CONSTRAINT_NAME, LIST_OF_ARC_INPUT, ARC_ARITY, ARC_GENERATORS, ARC_CONSTRAINTS, GRAPH_PROPERTIES)

- LIST_OF_ARC_INPUT is a list of collections used for creating the vertices of the initial graph. This was described at page 80 of Section 2.3.3.
- ARC_ARITY is the number of vertices of an arc. Arc arity was explained at page 82 of Section 2.3.3.
- ARC_GENERATORS is a list of arc generators. Arc generators were introduced at page 80 of Section 2.3.3.
- ARC_CONSTRAINTS is a list of arc constraints. Arc constraints were defined in Section 2.3.2 on page 57.
- GRAPH_PROPERTIES is a list of graph properties. Graph properties were described in Section 2.3.2 on page 68.

14. ctr_example(CONSTRAINT_NAME, LIST_OF_EXAMPLES)

- LIST_OF_EXAMPLES is a list of examples (usually one). Each example corresponds to a ground instance for which the constraint holds.

15. ctr_cond_imply(CONSTRAINT_NAME, IMPLIED_CONSTRAINT, LIST_OF_RESTRICTIONS_CTR, LIST_OF_RESTRICTIONS IMPLIED_CTR, MATCHING)

IMPLIED_CONSTRAINT is a constraint implied by CONSTRAINT_NAME provided that

- the list of restrictions LIST_OF_RESTRICTIONS_CTR holds for the constraint CONSTRAINT_NAME, and
- the list of restrictions LIST_OF_RESTRICTIONS IMPLIED_CTR holds for the constraint IMPLIED_CONSTRAINT.

MATCHING describes how to create the arguments of IMPLIED_CONSTRAINT from the arguments of CONSTRAINT_NAME. Note that some arguments of IMPLIED_CONSTRAINT may not be explicitly mentioned since they correspond to existentially quantified variables.

16. ctr_see_also(CONSTRAINT_NAME, LIST_OF_CONSTRAINTS)

- LIST_OF_CONSTRAINTS is a list of constraints that are related in some way to the constraint. Each element of the list is a fact of the form link(TYPE_OF_LINK, CONSTRAINT, STRING, SYMBOLS), where:
  - TYPE_OF_LINK is a semantic link that explains why we refer to CONSTRAINT. Semantic links were described in Section 2.6 on page 94.
  - CONSTRAINT is the name of the constraint that is linked to CONSTRAINT_NAME.
  - STRING is a string providing contextual explanation.
4.5. THE ELECTRONIC VERSION OF THE CATALOGUE

– **SYMBOLS** is a list of symbols (e.g., keywords, constraint names, mathematical expressions) that are inserted in STRING.

17. `ctr_key_words(CONSTRAINT_NAME, LIST_OF_KEYWORDS)`

- **LIST_OF_KEYWORDS** is a list of keywords associated with the constraint. Keywords may be linked to the *meaning* of the constraint, to a *typical pattern* where the constraint can be applied or to a *specific problem* where the constraint is useful. All keywords used in the catalogue are listed in alphabetic order in Section 3.7 on page 161. Each keyword has an entry explaining its meaning and providing the list of global constraints using that keyword.

18. `ctr_eval(CONSTRAINT_NAME, LIST_OF_EVALUATORS)`

- For many of the constraints of the catalogue one or several evaluators are provided. Each evaluator is explicitly described in **LIST_OF_EVALUATORS** by an element of the form `method(predicate_name)`, where `predicate_name` is the name of the Prolog predicate to call in order to evaluate the constraint,

1 Note that this predicate name should be different from existing SICStus built-ins

- **builtin** when the corresponding evaluator uses a SICStus built-in. This is the case, for example, for the `ALLDIFFERENT` constraint.
- **reformulation** when the corresponding evaluator reformulates the constraints in terms of a conjunction of constraints of the catalogue and/or in term of a conjunction of reified constraints. This is the case, for example, for the `TREE` constraint.
- **automaton** when the corresponding evaluator is based on an automaton that describes the set of solutions accepted by the constraint. The evaluator corresponds to the Prolog code that creates the signature constraints as well as the automata (usually one) associated with the constraint. A fact of the form `automaton/9` lists the states and the transitions of the automata used for describing the set of solutions accepted by the constraint. It follows the description provided in Section 2.4.2 on page 92. The `PATTERN` constraint is an example of constraint for which an automaton is provided.
- **logic** when the corresponding evaluator is based on a first order logic formula that describes the meaning of the constraint. This is the case, for example, for the `MEET_SBOXES` constraint.
- **checker** when the corresponding evaluator only accepts ground instances of the constraint. This is the case, for example, for the `CYCLE` constraint.

19. `ctr_sol(CONSTRAINT_NAME, SIZE, MINVAL, MAXVAL, NSOL, ARG_NSOL)`

- **SIZE** is the number of variables of the collection of variables.
- **MINVAL** is the smallest value of the variables of the sequence of variables.
- **MAXVAL** is the largest value of the variables of the sequence of variables.
- **NSOL** is the total number of solutions to the constraint, assuming a collection with **SIZE** items and all variables within interval `[MINVAL, MAXVAL]`.

Note that this predicate name should be different from existing SICStus built-ins.
ARGNSOL is a list, which for each value that can be assigned to an argument of the constraint, gives the corresponding number of solutions assuming we have a collection with SIZE items, and that all variables of the collection are assigned a value in interval [MINVAL, MAXVAL].

20. ctr_logic ( CONSTRAINT_NAME, LIST_OF_FIRST_ORDER_LOGIC_FORMULAE )

- LIST_OF_FIRST_ORDER_LOGIC_FORMULAE is a list of first order logical formulae that describe the meaning of the constraint [107].

4.5.2 XML schema associated with a global constraint

In this section we describe an XML schema associated with the global constraint catalogue. We present the motivation for this schema, how it integrates with the description of the constraint in the catalogue, and how the schema information is updated when the catalogue is modified.

Related work

There have been a number of approaches to defining an exchange format for constraint models.

The seminal OPL language [428] provides a modelling language for constraint programs, which is linked to Ilog's solver products. Its use an exchange format is limited by its proprietary background. MiniZinc [304] is a subset of the Zinc modelling language intended to be compiled to multiple solver implementations. First, a model in FlatZinc is generated from the MiniZinc model, removing all iteration (respectively recursion). The flat model can then be compiled into different solver implementations, currently Mercury, ECLiPSe and Gecode. The development of new back-ends is facilitated by the co-development of the Cadmium [410] term-rewriting system, which can parse and transform FlatZinc code.

The work most closely related to our format probably is the XML format used for the CSP solver competitions [425]. We reviewed an earlier draft version before generating our own schema for the catalogue, the 2007 version (for the 2008 competition) is described in [307]. It is intended as a solver independent format, which can be used by all participants of the competition. As a design choice, the authors decided not to fully structure the format, e.g. to use string values to hold structured information. In order to understand the actual meaning of the model, these strings need to be parsed and analysed as well. This may have size advantages for CSP data given in extensional form, but makes it more complex to check validity of a data file.

Key features

The following list summarises the core features of our XML format and the associated schema:

language independent The underlying description of the constraint in the catalogue is provided as Prolog facts. These may be difficult/tedious to read in other pro-
4.5. THE ELECTRONIC VERSION OF THE CATALOGUE

gramming languages. The use of XML as an exchange format allows use with most programming languages via provided XML parsers.

**machine readable, precise format** The format is precisely defined, using XML schema data types throughout, so that validity of a model can be checked with standard XML tools.

**one-to-one match with the data format used for the catalog** The internal structure of the schema follows the data format for the constraints in the rest of the catalogue. This minimises the need for relearning, once the basic format of the catalogue description has been understood.

**detailed description of the allowed format for arguments** For each global constraint, the allowed format of the argument is specified in great detail. As the complexity of global constraints increases, this becomes more and more important to simplify the generation of valid problem files.

**automated generation of schema from the catalogue data files** The schema is automatically generated from the catalogue data files by the simple generator program. This keeps the schema up-to-date with changes of the catalogue, and reduces the task of schema maintenance.

**generation of examples for each constraint** Example XML files based on the examples in the catalogue can be generated automatically, so that a link to these examples can be added to each catalogue entry.

**generation of diagrams describing schema for each constraint** At the same time, graph structures of the schema for each constraint can be automatically generated using the graphviz [193] tool. This can help a human user to produce XML data for a particular constraint without reading the details of the schema.

**Structure of schema**

**Model** The top-level element for the schema is model, which contains an optional variables element and a required constraints element.

**Variables** The variables element consists of a non-empty sequence of variable elements, each describing a single variable which may occur in some of the constraints. Each variable has some attributes, an required id, an optional name and a required external. The id is an XML schema ID used to refer to the variable in the constraints of the model, the name is a string which describes the variable to the user, and external is a “yes”/”no” string which states if the variable is visible outside the model.

The domains of variables are not described as part of the variables section, special unary constraints (e.g., IN_INTERVAL) are used in the constraint section instead.
4. FURTHER TOPICS

constraints  The constraints element consists of one or more elements representing constraints in the catalogue. The constraints can be stated in any order, with the understanding that the order may influence the sequence in which they are introduced to the solver.

For each constraint in the catalogue, a specific element with the same name is described in the schema. This imposes restrictions on the names of constraints in the catalogue, only alphanumerical names (with underscores) should be used.

Each constraint has attributes id (type ID), a name (type string) and an optional description (type string). The name and description can be used to include user-readable information about the constraint, for example, for debugging or explanations.

For each introduced element, a sequence of arguments is defined to define the arguments of the constraints in the same order as described in the catalogue. Each of the arguments has a specific type, which is defined in accordance with the catalogue definition. The argument names can be reused throughout the catalogue, as long as they are unique within each constraint. Arguments can have atomic values (i.e., consist of a single value), or they may be collection elements.

collection  Roughly, collections correspond to lists in Prolog. Collections can be empty, or must contain entries of the same type. Collections can be nested as required.

item  Items correspond to terms in Prolog. Items have named arguments, for which the same rules apply as for the arguments of constraints. The different arguments of an item can be of different type.

Generating schema from the catalogue

There are two programs which can be used to build the schema description from the data describing the catalogue. They should be run whenever a description of a constraint in the catalogue has been changed.

schema.ecl  The ECLiPSe [11] program schema.ecl can be used to re-generate the schema when the catalogue description has been modified. The query schema.produces the schema from descriptions in the src directory, the query top. produces example files for each constraint in the xml directory.

The predicate handle_table defines which of the restrictions in the constraint description are included as part of the schema information. Many of the more complex rules cannot be easily checked by the schema, an entry in handle_table says to ignore the restriction for the moment.

schema.dot.ecl  The program schema.dot.ecl can be used to generate graphviz dot files from the schema file schema.xsd. The generated files are placed in the images directory, and a dot command to produce .png and .eps output is run in the same directory. The pixel based png files are intended for use in web pages, the scalable eps files can be used in \LaTeX files producing postscript or pdf documents.
There are some predicates in `schema_dot.ecl` which control the format of the generated graph. They are:

- The predicate `range_style` controls the display of range information, and optional/required choices for attributes.
- The predicate `type_shape` defines the shape and colour of the different elements in the schema for a constraint.
- The predicate `match_builtin` provides an abbreviated element name for some of the predefined element types in the schema. This is required as the graphs should not become too big to fit onto a single A4 page in the output.

**Conclusion**

We have described the rationale and details for an XML schema attached to the global constraint catalogue. It allows to describe models using the constraints of the catalogue as flat XML files, which are a good exchange format for generating and/or parsing constraint data.

Keywords

- **Constraint arguments**: binary constraint, pure functional dependency.
- **Constraint type**: predefined constraint, arithmetic constraint.
- **Filtering**: arc-consistency.
- **Modelling**: functional dependency.
5.2 ALL_BALANCE

Origin  
derived from BALANCE in [77]

Constraint  
ALL_BALANCE(BALANCE, VARIABLES, M)

Arguments  
BALANCE : dvar  
VARIABLES : collection(var − dvar)  
M : int

Restrictions  
BALANCE ≥ 0  
BALANCE ≤ |VARIABLES|  
required(VARIABLES, var)  
VARIABLES.var ≥ 1  
VARIABLES.var ≤ M  
M ≥ 1  
M ≤ |VARIABLES|

Purpose  
BALANCE is equal to the difference between the number of occurrence of the value that occurs the most and the value that occurs the least within the collection of variables VARIABLES, where we consider the number of occurrences of each value in [1, M].

Example  
(2, ⟨3, 1, 2, 1, 1⟩, 3)  
(3, ⟨3, 1, 2, 1, 1⟩, 4)

1. In the first example, values 1, 2 and M = 3 are respectively used 3, 1 and 1 times. The corresponding ALL_BALANCE constraint holds since its first argument BALANCE is assigned to the difference between the maximum and minimum number of the previous occurrences (i.e., 3 − 1).

2. In the first example, values 1, 2, 3 and M = 4 are respectively used 3, 1, 1 and 0 times. The corresponding ALL_BALANCE constraint holds since its first argument BALANCE is assigned to the difference between the maximum and minimum number of the previous occurrences (i.e., 3 − 0).

All solutions  
Figure 5.2 gives all solutions to the following non ground instance of the ALL_BALANCE constraint: BALANCE ∈ {0, 3}, V_1 ∈ [0, 5], V_2 ∈ [2, 6], V_3 ∈ [0, 1], V_4 ∈ [1, 2], ALL_BALANCE(BALANCE, ⟨V_1, V_2, V_3, V_4⟩, 4).

Typical  
BALANCE ≤ 2 + |VARIABLES|/10  
|VARIABLES| > 2
Typical model \( \text{nval}(\text{VARIABLES}.\text{var}) > 2 \)

Arg. properties Functional dependency: BALANCE determined by VARIABLES and M.

Usage An application of the ALL_BALANCE constraint is to enforce a balanced assignment of values, no matter how many distinct values will be used. In this case one will push down the maximum value of the first argument of the ALL_BALANCE constraint.

- On the one hand the ALL_BALANCE constraint should be used on problems where only consecutive values are used. This is the case, for example, in some resource assignment problems where we know in advance that all resources will be employed.
- On the other hand the BALANCE constraint should be used on problems for which, due to some constraints, not all consecutive values will be assigned. This is the case, for example, for some frequency assignment problems where, due to some interference, all used values are not necessarily consecutive.

Algorithm When the lower bound of the BALANCE argument is unconstrained, a flow-based polynomial filtering algorithm for the ALL_BALANCE constraint achieving arc-consistency is described in [77].

Reformulation An efficient reformulation of the ALL_BALANCE constraint is provided in [77]. It is based on the following ingredients:

- First, a \( \text{GLOBAL\_CARDINALITY}(\text{VARIABLES}, \langle 1 \ o_1, 2 \ o_2, \ldots, M \ o_M \rangle) \) constraint is stated for exposing the number of occurrences \( o_1, o_2, \ldots, o_M \) of values 1, 2, \ldots, \( M \) within the values assigned to VARIABLES.
- Second, a \( \text{MINIMUM}(\text{min}, \langle o_1, o_2, \ldots, o_k \rangle) \) and a \( \text{MAXIMUM}(\text{max}, \langle o_1, o_2, \ldots, o_k \rangle) \) constraints on variables \( o_1, o_2, \ldots, o_k \) are stated to get the corresponding smallest and largest values \( \text{min} \) and \( \text{max} \). Then, to express the link with BALANCE, the constraint \( \text{BALANCE} = \text{max} - \text{min} \) is stated.
- Third, the following necessary conditions are used:
  (i) \( M \cdot \text{max} - (M - 1) \cdot \text{BALANCE} \leq |\text{VARIABLES}| \),
  (ii) \( M \cdot \text{min} + (M - 1) \cdot \text{BALANCE} \geq |\text{VARIABLES}| \).
(iii) $\text{BALANCE} \neq 1 + \left\lfloor \frac{\text{VARIABLES}}{n} \right\rfloor - \left\lceil \frac{\text{VARIABLES}}{n} \right\rceil$.

In the same paper [77], it is also shown how to generate stronger necessary conditions.

See also related: BALANCE (ignore unused values).

Keywords

- application area: assignment.
- constraint arguments: pure functional dependency.
- constraint type: value constraint.
- filtering: flow.
- modelling: balanced assignment, functional dependency.
ALL_BALANCE

497
5.3 ALL_DIFFER_FROM_AT_LEAST_K_POS

**Origin**
Inspired by [188].

**Constraint**
\[
\text{ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS}(K, \text{VECTORS})
\]

**Type**
\[
\text{VECTOR} : \text{collection}(\text{var} - \text{dvar})
\]

**Arguments**
\[
K : \text{int} \\
\text{VECTORS} : \text{collection}(\text{vec} - \text{VECTOR})
\]

**Restrictions**
\[
\begin{align*}
\text{required}(\text{VECTOR}, \text{var}) \\
|\text{VECTOR}| & \geq 1 \\
|\text{VECTOR}| & \geq K \\
K & \geq 0 \\
\text{required}(\text{VECTORS}, \text{vec}) \\
\text{same\_size}(\text{VECTORS}, \text{vec})
\end{align*}
\]

**Purpose**
Enforce all pairs of distinct vectors of the \text{VECTORS} collection to differ from at least \(K\) positions.

**Example**
\[
(2, (\text{vec} - \langle 2, 5, 2, 0 \rangle, \text{vec} - \langle 3, 6, 2, 1 \rangle, \text{vec} - \langle 3, 6, 1, 0 \rangle))
\]

The \text{ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS} constraint holds since:

- The first and second vectors differ from 3 positions, which is greater than or equal to \(K = 2\).
- The first and third vectors differ from 3 positions, which is greater than or equal to \(K = 2\).
- The second and third vectors differ from 2 positions, which is greater than or equal to \(K = 2\).

**Typical**
\[
K > 0 \\
|\text{VECTORS}| > 1
\]

**Symmetries**
- Items of \text{VECTORS} are permutable.
- Items of \text{VECTORS}.\text{vec} are permutable \textit{(same permutation used)}.

**Arg. properties**
- \textbf{Contractible} wrt. \text{VECTORS}.
- \textbf{Extensible} wrt. \text{VECTORS}.\text{vec} \textit{(add items at same position)}.
See also

- **implied by**: `ALL_DIFFER_FROM_EXACTLY_K_POS` (`\geq K` replaced by `= K`).
- **part of system of constraints**: `DIFFER_FROM_AT_LEAST_K_POS`.
- **used in graph description**: `DIFFER_FROM_AT_LEAST_K_POS`.

**Keywords**

- **application area**: bioinformatics.
- **characteristic of a constraint**: disequality, vector.
- **constraint type**: system of constraints, decomposition.
- **final graph structure**: no loop, symmetric.

**Cond. implications**

- \[ \text{ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS}(K, \text{VECTORS}) \]
  - with \( K \leq |\text{VECTORS}| \)
  - implies \[ \text{ATLEAST\_NVECTOR}(\text{NVEC}, \text{VECTORS}). \]
**Arc input(s)**

VECTORS

**Arc generator**

\( CLIQUE(\neq) \mapsto \text{collection}(\text{vectors1}, \text{vectors2}) \)

**Arc arity**

2

**Arc constraint(s)**

\( \text{DIFFER FROM AT LEAST K POS}(K, \text{vectors1.vec}, \text{vectors2.vec}) \)

**Graph property(ies)**

\( \text{NARC}=|\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}| \)

**Graph class**

- \text{NO LOOP}
- \text{SYMMETRIC}

---

**Graph model**

The Arc constraint(s) slot uses the \text{DIFFER FROM AT LEAST K POS} constraint defined in this catalogue.

Parts (A) and (B) of Figure 5.3 respectively show the initial and final graph associated with the Example slot. Since we use the \text{NARC} graph property, the arcs of the final graph are stressed in bold. The previous constraint holds since exactly \(3 \cdot (3 - 1) = 6\) arc constraints hold.

![Initial and final graph of the \text{ALL_DIFFER_FROM_AT_LEAST_K_POS} constraint](image)

**Signature**

Since we use the \( CLIQUE(\neq) \) arc generator on the items of the VECTORS collection, the expression \(|\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|\) corresponds to the maximum number of arcs of the final graph. Therefore we can rewrite the graph property \( \text{NARC}=|\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}| \) to \( \text{NARC} \geq |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}| \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).
ALL DIFFER FROM AT LEAST K POS

501
### 5.4 ALL_DIFFER_FROM_AT_MOST_K_POS

**Origin**

Inspired by ALL_DIFFER_FROM_AT_LEAST_K_POS.

**Constraint**

\[
\text{ALL_DIFFER_FROM_AT_MOST_K_POS}(K, \text{VECTORS})
\]

**Type**

\[
\text{VECTOR} : \text{collection}(\text{var} - \text{dvar})
\]

**Arguments**

\[
\begin{align*}
K & : \text{int} \\
\text{VECTORS} & : \text{collection}(\text{vec} - \text{VECTOR})
\end{align*}
\]

**Restrictions**

\[
\begin{align*}
\text{required}(\text{VECTOR}, \text{var}) \\
|\text{VECTOR}| \geq 1 \\
|\text{VECTOR}| \geq K \\
K \geq 0 \\
\text{required}(\text{VECTORS}, \text{vec}) \\
\text{same_size}(\text{VECTORS}, \text{vec})
\end{align*}
\]

**Purpose**

Enforce all pairs of distinct vectors of the \text{VECTORS} collection to differ from at most \(K\) positions.

**Example**

\[
(2, (\text{vec} - \langle 0, 3, 0, 6 \rangle, \text{vec} - \langle 0, 3, 4, 1 \rangle, \text{vec} - \langle 0, 3, 4, 6 \rangle))
\]

The ALL_DIFFER_FROM_AT_MOST_K_POS constraint holds since:

- The first and second vectors differ from 2 positions, which is less than or equal to \(K = 2\).
- The first and third vectors differ from 1 position, which is less than or equal to \(K = 2\).
- The second and third vectors differ from 1 position, which is less than or equal to \(K = 2\).

**Typical**

\[
\begin{align*}
K > 0 \\
K < |\text{VECTOR}| \\
|\text{VECTORS}| > 1
\end{align*}
\]

**Symmetries**

- Items of \text{VECTORS} are \text{permutable}.
- Items of \text{VECTORS}.vec are \text{permutable} (\text{same permutation used}).

**Arg. properties**

- \text{Contractible} wrt. \text{VECTORS}.
- \text{Contractible} wrt. \text{VECTORS}.vec (\text{remove items from same position}).
See also

**implied by:** \( \text{ALL\_DIFFER\_FROM\_AT\_MOST\_K\_POS} \ (\leq K \text{ replaced by } = K) \).

**part of system of constraints:** \( \text{DIFFER\_FROM\_AT\_MOST\_K\_POS} \).

**used in graph description:** \( \text{DIFFER\_FROM\_AT\_MOST\_K\_POS} \).

Keywords

**characteristic of a constraint:** disequality, vector.

**constraint type:** system of constraints, decomposition.

**final graph structure:** no loop, symmetric.
### Arc input(s)
- **VECTORS**

### Arc generator
- $CLIQUE(\neq) \mapsto \text{collection}(\text{vectors1, vectors2})$

### Arc arity
- 2

### Arc constraint(s)
- $\text{DIFFER\_FROM\_AT\_MOST\_K\_POS}(K, \text{vectors1.vec, vectors2.vec})$

### Graph property(ies)
- $\text{NARC} = |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$

### Graph class
- • NO\_LOOP
  - • SYMMETRIC

### Graph model
The Arc constraint(s) slot uses the $\text{DIFFER\_FROM\_AT\_MOST\_K\_POS}$ constraint defined in this catalogue.

Parts (A) and (B) of Figure 5.4 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold. The previous constraint holds since exactly $3 \cdot (3 - 1) = 6$ arc constraints hold.

![Figure 5.4: Initial and final graph of the ALL\_DIFFER\_FROM\_AT\_MOST\_K\_POS constraint](image)

### Signature
Since we use the $CLIQUE(\neq)$ arc generator on the items of the VECTORS collection, the expression $|\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$ corresponds to the maximum number of arcs of the final graph. Therefore we can rewrite the graph property $\text{NARC} = |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$ to $\text{NARC} \geq |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$. This leads to simplify $\text{NARC}$ to $\text{NARC}$. 
ALL_DIFFER_FROM_AT_MOST_K_POS
5.5 ALL_DIFFER_FROM_EXACTLY_K_POS

Origin
Inspired by ALL_DIFFER_FROM_AT_LEAST_K_POS.

Constraint
ALL_DIFFER_FROM_EXACTLY_K_POS(K, VECTORS)

Type
VECTOR : collection(var − dvar)

Arguments
K : int
VECTORS : collection(vec − VECTOR)

Restrictions
required(VECTOR, var)
|VECTOR| ≥ 1
|VECTOR| ≥ K
K ≥ 0
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose
Enforce all pairs of distinct vectors of the VECTORS collection to differ from exactly K positions. Enforce K = 0 when |VECTORS| < 2.

Example
(2, (vec − ⟨0, 3, 0, 6⟩, vec − ⟨0, 3, 4, 1⟩, vec − ⟨9, 3, 4, 6⟩))

The ALL_DIFFER_FROM_EXACTLY_K_POS constraint holds since:

- The first and second vectors differ from 2 positions, which is equal to K = 2.
- The first and third vectors differ from 2 positions, which is equal to K = 2.
- The second and third vectors differ from 2 positions, which is equal to K = 2.

All solutions
Consider the following colouring problem where we have to colour each block of a parquet so that in any pair of rows (respectively columns) exactly two adjacent blocks are coloured with the same colour (pink or cyan). The problem is known under the name parquets anallagmatiques in [280]. To model this problem we post two ALL_DIFFER_FROM_EXACTLY_K_POS constraints: a first one for the rows and a second one for the columns. To break some symmetry (1) we fix X_{11} to 0 since values 0 and 1 are interchangeable, and (2) we order lexicographically the rows by enforcing a LEX_CHAIN_LESSEQ constraint. Finally to limit the number of solutions we restrict X_{12} to

1. Figure 5.5 provides the six solutions to the previous problem.

\[
\begin{align*}
X_{11} &\in [0, 1], X_{12} \in [0, 1], X_{13} \in [0, 1], X_{14} \in [0, 1], \\
X_{21} &\in [0, 1], X_{22} \in [0, 1], X_{23} \in [0, 1], X_{24} \in [0, 1], \\
X_{31} &\in [0, 1], X_{32} \in [0, 1], X_{33} \in [0, 1], X_{34} \in [0, 1], \\
X_{41} &\in [0, 1], X_{42} \in [0, 1], X_{43} \in [0, 1], X_{44} \in [0, 1], \\
X_{11} &= 0,
\end{align*}
\]

6 & \mathcal{L} \left( \langle 0, 1, 1, 1 \rangle, \langle 1, 0, 1, 1 \rangle, \langle 1, 1, 0, 1 \rangle, \langle 1, 1, 1, 0 \rangle \rangle \\
\end{align*}

Figure 5.5: Parquet flooring such that for every pair of rows and for every pair of columns we have exactly two adjacent blocks with the same colour (to every variable corresponds a block for which the value is mapped to a colour, pink for 0 and cyan for 1)

Typical
\begin{align*}
K & > 0 \\
K & < |\text{VECTOR}| \\
|\text{VECTORS}| & > 1
\end{align*}

Symmetries
\begin{itemize}
\item Items of VECTORS are permutable.
\item Items of VECTORS.vec are permutable (same permutation used).
\end{itemize}
Arg. properties

Contractible wrt. VECTORS.

See also

implies: ALL_DIFFER_FROM_AT_LEAST_K_POS (\(= k \ replaced \ by \ \geq \ k\)),
ALL_DIFFER_FROM_AT_MOST_K_POS (\(= k \ replaced \ by \ \leq \ k\)).

part of system of constraints: DIFFER_FROM_EXACTLY_K_POS.
used in graph description: DIFFER_FROM_EXACTLY_K_POS.

Keywords

characteristic of a constraint: disequality, vector.
constraint type: system of constraints, decomposition.
final graph structure: no loop, symmetric.

Cond. implications

ALL_DIFFER_FROM_EXACTLY_K_POS(K, VECTORS)
with \(K \leq |VECTORS|\)
implies ATLEAST_NVECTOR(NVEC, VECTORS).
Arc input(s)  VECTORS
Arc generator  $\textit{CLIQUE}(\neq) \mapsto \text{collection}(\text{vectors1}, \text{vectors2})$
Arc arity  2
Arc constraint(s)  $\textit{DIFFER\_FROM\_EXACTLY\_K\_POS}(K, \text{vectors1}.\text{vec}, \text{vectors2}.\text{vec})$
Graph property(ies)  $\textit{NARC} = |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$
Graph class  
  ● NO LOOP  
  ● SYMMETRIC

Graph model

The Arc constraint(s) slot uses the $\textit{DIFFER\_FROM\_EXACTLY\_K\_POS}$ constraint defined in this catalogue.

Parts (A) and (B) of Figure 5.6 respectively show the initial and final graph associated with the Example slot. Since we use the $\textit{NARC}$ graph property, the arcs of the final graph are stressed in bold. The previous constraint holds since exactly $3 \cdot (3 - 1) = 6$ arc constraints hold.

![Figure 5.6: Initial and final graph of the \textit{ALL\_DIFFER\_FROM\_EXACTLY\_K\_POS} constraint](image)

Signature

Since we use the $\textit{CLIQUE}(\neq)$ arc generator on the items of the $\text{VECTORS}$ collection, the expression $|\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$ corresponds to the maximum number of arcs of the final graph. Therefore we can rewrite the graph property $\textit{NARC} = |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$ to $\textit{NARC} \geq |\text{VECTORS}| \cdot |\text{VECTORS}| - |\text{VECTORS}|$. This leads to simplify $\textit{NARC}$ to $\textit{NARC}$. 
### 5.6 ALL_EQUAL

**Origin**
Derived from SOFT_ALL_EQUAL_MIN_CTR

**Constraint**
ALL_EQUAL(VARIABLES)

**Synonym**
REL.

**Argument**
VARIABLES : collection(var−dvar)

**Restrictions**
required(VARIABLES, var)  
|VARIABLES| > 0

**Purpose**
Enforce all variables of the collection VARIABLES to take the same value.

**Example**
\[(5, 5, 5, 5)\]

The ALL_EQUAL constraint holds since all its variables are fixed to value 5.

**All solutions**
Figure 5.7 gives all solutions to the following non ground instance of the ALL_EQUAL constraint: \(V_1 \in [0, 6], V_2 \in [0, 2], V_3 \in [0, 2], V_4 \in [1, 4], \text{ALL_EQUAL}(\langle V_1, V_2, V_3, V_4 \rangle)\).

Figure 5.7: All solutions corresponding to the non ground example of the ALL_EQUAL constraint of the All solutions slot

**Typical**
|VARIABLES| > 2  
\(\text{minval}(\text{VARIABLES}.\text{var}) \neq 0\)

**Typical model**
\(\text{nval}(\text{VARIABLES}.\text{var}) > 2\)

**Symmetries**
- Items of VARIABLES are permutable.
- All occurrences of a value of VARIABLES.var can be renamed to any unused value.

**Arg. properties**
Contractible wrt. VARIABLES.

**Counting**
Number of solutions for ALL_EQUAL: domains $0..n$

\hline
\textbf{Arc generator} & \textit{PATH}→\textit{collection}(\textsc{variables1}, \textsc{variables2}) \\
\hline
\textbf{Arc arity} & 2 \\
\hline
\textbf{Arc constraint(s)} & \textsc{variables1}.\text{var} = \textsc{variables2}.\text{var} \\
\hline
\textbf{Graph property(ies)} & \textsc{NARC}= |\textsc{variables}| − 1 \\
\hline
\end{tabular}
\end{figure}
```

Figure 5.8: Initial and final graph of the \textsc{ALL_EQUAL} constraint
5.7 ALL_EQUAL_EXCEPT_0

Origin
Derived from ALL_EQUAL.

Constraint
ALL_EQUAL_EXCEPT_0(VARIABLES)

Argument
VARIABLES : collection(var−dvar)

Restrictions
required(VARIABLES.var)
|VARIABLES| > 0

Purpose
Enforce all variables of the collection VARIABLES that are different from 0 to take the same value.

Example
((5, 0, 5))
The ALL_EQUAL_EXCEPT_0 constraint holds since all its variables are fixed to values 0 or 5.

Typical
|VARIABLES| > 1

Typical model
ATLEAST(2, VARIABLES, 0)
nval(VARIABLES.var) > 2

Symmetries
• Items of VARIABLES are permutable.

• All occurrences of two distinct values of VARIABLES.var that are both different from 0 can be swapped; all occurrences of a value of VARIABLES.var that is different from 0 can be renamed to any unused value that is also different from 0.

Arg. properties
Contractible wrt. VARIABLES.

See also
implied by: ALL_EQUAL, GLOBAL_CONTIGUITY.

Keywords
characteristic of a constraint: joker value, automaton, automaton with counters.

constraint type: value constraint.
Automaton

Figure 5.9 depicts an automaton that only accepts all the solutions to the `ALL_EQUAL_EXCEPT_0` constraint. This automaton uses a counter in order to record the value of the first non-zero variable `VAR_i` already encountered. To each variable `VAR_i` of the collection `VARIABLES` corresponds a 0-1 signature variable `S_i`. The following signature constraint links `VAR_i` and `S_i`: `VAR_i \neq 0 \Leftrightarrow S_i`.

\[
\begin{align*}
    & \{ C \leftarrow 0 \} \\
    & \{ \text{VAR}_i \neq 0, \} \\
    & \{ \text{VAR}_i = 0 \}
\end{align*}
\]

Figure 5.9: Automaton (with one counter) of the `ALL_EQUAL_EXCEPT_0` constraint

Figure 5.10: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the `ALL_EQUAL_EXCEPT_0` constraint
5.8 ALL_EQUAL_PEAK

Origin

Derived from PEAK and ALL_EQUAL.

Constraint

ALL_EQUAL_PEAK(VARIABLES)

Argument

VARIABLES : collection(var−dvar)

Restrictions

|VARIABLES| > 0
required(VARIABLES, var)

Purpose

A variable \( V_k \) \((1 < k < m)\) of the sequence of variables \( \text{VARIABLES} = V_1, \ldots, V_m \) is a peak if and only if there exists an \( i \) \((1 < i \leq k)\) such that \( V_{i−1} < V_i \) and \( V_i = V_{i+1} = \cdots = V_k \) and \( V_k > V_{k+1} \).

Enforce all the peaks of the sequence \( \text{VARIABLES} \) to be assigned the same value, i.e. to be located at the same altitude.

Example

\(((1,5,5,4,3,5,2,7))\)

The ALL_EQUAL_PEAK constraint holds since the two peaks, in bold, of the sequence 1 5 5 4 3 5 2 7 are located at the same altitude 5. Figure 5.11 depicts the solution associated with the example.

![Illustration of the Example slot: a sequence of eight variables \( V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8 \) respectively fixed to values 1, 5, 5, 4, 3, 5, 2, 7 and its corresponding two peaks, in red, both located at altitude 5.]

Note that the ALL_EQUAL_PEAK constraint does not enforce that the maximum value of the sequence \( \text{VARIABLES} \) corresponds to the altitude of its peaks since, as shown by the
example, the sequence can end up with an increasing subsequence that go beyond the altitude of its peaks. It also does not enforce that the sequence VARIABLES contains at least one peak.

**All solutions**

Figure 5.12 gives all solutions to the following non ground instance of the ALL_EQUAL_PEAK constraint: $V_1 \in \{0, 5\}$, $V_2 \in [2, 3]$, $V_3 = 2$, $V_4 \in [3, 4]$, $V_5 = 1$, $\text{ALL_EQUAL_PEAK}((V_1, V_2, V_3, V_4, V_5))$.

![Diagram of solutions](image)

**Typical**

- $|\text{VARIABLES}| \geq 5$
- $\text{range(\text{VARIABLES}.var)} > 1$
- $\text{PEAK(\text{VARIABLES}.var)} \geq 2$

**Typical model**

- $\text{nval(\text{VARIABLES}.var)} > 2$

**Symmetries**

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

**Arg. properties**

- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

**Counting**

  - implies \( \text{SOME_EQUAL(VARIABLES)} \).

- \( \text{ALL_EQUAL_PEAK_MAX(VARIABLES)} \)
  - with \( \text{PEAK(VARIABLES.var) > 0} \)
  - implies \( \text{NOT_ALL_EQUAL(VARIABLES)} \).
Automaton

Figure 5.16 depicts the automaton associated with the \texttt{ALL_EQUAL_PEAK_MAX} constraint. To each pair of consecutive variables (VAR$_{i}$, VAR$_{i+1}$) of the collection VARIABLES corresponds a signature variable $S_i$. The following signature constraint links VAR$_{i}$, VAR$_{i+1}$ and $S_i$: (VAR$_{i}$ < VAR$_{i+1}$ $\iff$ $S_i = 0$) $\land$ (VAR$_{i}$ = VAR$_{i+1}$ $\iff$ $S_i = 1$) $\land$ (VAR$_{i}$ > VAR$_{i+1}$ $\iff$ $S_i = 2$).

**STATE SEMANTICS**

$s$ : initial stationary or decreasing mode

$i$ : increasing (before first potential peak) mode

$j$ : decreasing (after a peak) mode

$k$ : increasing (after a peak) mode

Figure 5.16: Automaton for the \texttt{ALL_EQUAL_PEAK_MAX} constraint; note the conditional transition from state $k$ to state $j$ testing that the counter Altitude is equal to VAR$_{i}$ for enforcing that all peaks are located at the same altitude; the conditional transitions from $j$ to $k$ and from $k$ to $k$ and the final check $\text{Altitude} \geq \text{VAR}_{\text{VARIABLES}}$ enforce the maximum value of the sequence VARIABLES to not exceed the altitude of the eventual peaks.

Figure 5.17: Hypergraph of the reformulation corresponding to the automaton of the \texttt{ALL_EQUAL_PEAK_MAX} constraint where $A$ stands for the value of the counter Altitude (since all states of the automaton are accepting there is no restriction on the last variable $Q_{n-1}$)
5.10 ALL_EQUAL_VALLEY

Origin: Derived from VALLEY and ALL_EQUAL.

Constraint: ALL_EQUAL_VALLEY(VARIABLES)

Argument: VARIABLES : collection(var−dvar)

Restrictions: |VARIABLES| > 0
required(VARIABLES, var)

A variable $V_k$ ($1 < k < m$) of the sequence of variables $VARIABLES = V_1, \ldots, V_m$ is a valley if and only if there exists an $i$ ($1 < i \leq k$) such that $V_{i-1} > V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k < V_{k+1}$.

Purpose: Enforce all the valleys of the sequence $VARIABLES$ to be assigned the same value, i.e. to be located at the same altitude.

Example: $((1, 5, 5, 4, 2, 2, 6, 2, 7))$

The ALL_EQUAL_VALLEY constraint holds since the two valleys, in bold, of the sequence $1 \ 5 \ 5 \ 4 \ 2 \ 2 \ 6 \ 2 \ 7$ are located at the same altitude 2. Figure 5.18 depicts the solution associated with the example.

Figure 5.18: Illustration of the Example slot: a sequence of nine variables $V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9$ respectively fixed to values 1, 5, 5, 4, 2, 2, 6, 2, 7 and its corresponding two valleys, in red, both located at altitude 2.

Note that the ALL_EQUAL_VALLEY constraint does not enforce that the minimum value of the sequence $VARIABLES$ corresponds to the altitude of its valleys since, as shown by
the example, the sequence can start with an increasing subsequence that starts below the altitude of its valleys. It also does not enforce that the sequence VARIABLES contains at least one valley.

**All solutions**

Figure 5.19 gives all solutions to the following non ground instance of the ALL_EQUAL_VALLEY constraint: \( V_1 \in \{0, 5\}, V_2 \in [2, 3], V_3 = 4, V_4 \in [1, 2], V_5 \in [4, 5], \) ALL_EQUAL_VALLEY\((\langle V_1, V_2, V_3, V_4, V_5 \rangle)\).

Figure 5.19: All solutions corresponding to the non ground example of the ALL_EQUAL_VALLEY constraint of the **All solutions** slot where each valley is coloured in orange

**Typical**

\[
|\text{VARIABLES}| \geq 5 \quad \text{range}(\text{VARIABLES}.\text{var}) > 1 \quad \text{VALLEY}(\text{VARIABLES}.\text{var}) \geq 2
\]

**Typical model**

\( \text{nval}(\text{VARIABLES}.\text{var}) > 2 \)

**Symmetries**

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

**Arg. properties**

- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

**Counting**

Number of solutions for ALL_EQUAL_VALLEY: domains 0..n
See also

implied by: ALL_EQUAL_VALLEY_MIN.
implies: DECREASING_VALLEY, INCREASING_VALLEY.
related: ALL_EQUAL_PEAK, VALLEY.
Keywords

- **characteristic of a constraint**: automaton, automaton with counters, automaton with same input symbol.
- **combinatorial object**: sequence.
- **constraint network structure**: sliding cyclic(1) constraint network(2).

Cond. implications

- \( \text{ALL}\_\text{EQUAL}\_\text{VALLEY}(\text{VARIABLES}) \) with \( \text{VALLEY}(\text{VARIABLES}.\text{var}) > 1 \) implies \( \text{SOME}\_\text{EQUAL}(\text{VARIABLES}) \).

- \( \text{ALL}\_\text{EQUAL}\_\text{VALLEY}(\text{VARIABLES}) \) with \( \text{VALLEY}(\text{VARIABLES}.\text{var}) > 0 \) implies \( \text{NOT}\_\text{ALL}\_\text{EQUAL}(\text{VARIABLES}) \).
**Automaton**

Figure 5.20 depicts the automaton associated with the `ALL_EQUAL_VALLEY` constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection `VARIABLES` corresponds a signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i\), \(\text{VAR}_{i+1}\) and \(S_i\):

\[
\begin{align*}
& (\text{VAR}_i < \text{VAR}_{i+1} \leftrightarrow S_i = 0) \land \\
& (\text{VAR}_i = \text{VAR}_{i+1} \leftrightarrow S_i = 1) \land \\
& (\text{VAR}_i > \text{VAR}_{i+1} \leftrightarrow S_i = 2).
\end{align*}
\]

### STATE SEMANTICS

- \(s\) : initial stationary or increasing mode \((\{=|>\}^*)\)
- \(i\) : decreasing (before first potential valley) mode \((<|<|\}^*)\)
- \(j\) : increasing (after a valley) mode \((>|>|\}^*)\)
- \(k\) : decreasing (after a valley) mode \((|<|<\}^*)\)

**Figure 5.20:** Automaton for the `ALL_EQUAL_VALLEY` constraint (note the conditional transition from state \(k\) to state \(j\) testing that the counter `Altitude` is equal to `VAR_i` for enforcing that all valleys are located at the same altitude)

**Figure 5.21:** Hypergraph of the reformulation corresponding to the automaton of the `ALL_EQUAL_VALLEY` constraint where \(A_i\) stands for the value of the counter `Altitude` (since all states of the automaton are accepting there is no restriction on the last variable \(Q_{n-1}\))
5.11  ALL_EQUAL_VALLEY_MIN

Origin  
Derived from **VALLEY** and **ALL_EQUAL**.

Constraint  
**ALL_EQUAL_VALLEY_MIN(VARIABLES)**

Argument  
**VARIABLES** : collection(var−dvar)

Restrictions  

\[ |\text{VARIABLES}| > 0 \]
\[ \text{required(VARIABLES, var)} \]

Purpose  

A variable \( V_k \) (1 < \( k < m \)) of the sequence of variables \( \text{VARIABLES} = V_1, \ldots, V_m \) is a valley if and only if there exists an \( i \) (1 < \( i \leq k \)) such that \( V_{i−1} > V_i \) and \( V_i = V_{i+1} = \cdots = V_k \) and \( V_k < V_{k+1} \).

Enforce all the valleys of the sequence **VARIABLES** to be assigned the same value, i.e. to be located at the same altitude corresponding to the minimum value of the sequence **VARIABLES**.

Example  

\[((2,5,5,4,2,6,2,7))\]

The **ALL_EQUAL_VALLEY_MIN** constraint holds since the two valleys, in bold, of the sequence 2 5 5 4 2 6 2 7 are located at the same altitude 2 that is also the minimum value of the sequence 2 5 5 4 2 6 2 7. Figure 5.22 depicts the solution associated with the example.

Note that the **ALL_EQUAL_VALLEY_MIN** constraint does not enforce that the sequence **VARIABLES** contains at least one valley.

Typical  

\[ |\text{VARIABLES}| \geq 5 \]
\[ \text{range(VARIABLES.var)} > 1 \]
\[ \text{VALLEY(VARIABLES.var)} \geq 2 \]

Typical model  

\[ \text{nval(VARIABLES.var)} > 2 \]

Symmetries  

- Items of **VARIABLES** can be **reversed**.
- One and the same constant can be **added** to the **var** attribute of all items of **VARIABLES**.

Arg. properties  

- **Prefix-contractible** wrt. **VARIABLES**.
- **Suffix-contractible** wrt. **VARIABLES**.

Counting
Figure 5.22: Illustration of the Example slot: a sequence of nine variables $V_1$, $V_2$, $V_3$, $V_4$, $V_5$, $V_6$, $V_7$, $V_8$, $V_9$ respectively fixed to values 2, 5, 5, 4, 2, 2, 6, 2, 7 and its corresponding two valleys, in red, both located at altitude 2 that also corresponds to the minimum value of the sequence.

Figure 5.24: Hypergraph of the reformulation corresponding to the automaton of the \texttt{ALL\_EQUAL\_VALLEY\_MIN} constraint where \texttt{A} stands for the value of the counter \texttt{Altitude} (since all states of the automaton are accepting there is no restriction on the last variable \texttt{Q}_{n-1})
5.12 ALL_INCOMPARABLE

Origin
Inspired by incomparable rectangles.

Constraint
ALL_INCOMPARABLE(VECTORS)

Synonym
ALL_INCOMPARABLES.

Type
VECTOR : collection(var−dvar)

Argument
VECTORS : collection(vec − VECTOR)

Restrictions
required(VECTOR, var)
|VECTOR| ≥ 1
required(VECTORS, vec)
|VECTORS| ≥ 1
same_size(VECTORS, vec)

Purpose
Enforce for each pair of distinct vectors of the VECTORS collection the fact that they are incomparable. Two vectors VECTOR1 and VECTOR2 are incomparable if and only when the components of both vectors are ordered, and respectively denoted by SVECTOR1 and SVECTOR2, we neither have SVECTOR1[i].var ≤ SVECTOR2[i].var (for all i ∈ [1, |SVECTOR1|]) nor have SVECTOR2[i].var ≤ SVECTOR1[i].var (for all i ∈ [1, |SVECTOR1|]).

Example

\[
\begin{pmatrix}
vec = (1.18), \\
vec = (2.16), \\
vec = (3.13), \\
\langle vec = (4.11), \rangle \\
vec = (5.10), \\
vec = (6.9), \\
vec = (7.7)
\end{pmatrix}
\]

The ALL_INCOMPARABLE constraint holds since all distinct pairs of vectors are incomparable as illustrated by Figure 5.25.

All solutions
Figure 5.26 gives all solutions to the following non ground instance of the ALL_INCOMPARABLE constraint: \(U_1 \in [1, 2], V_1 \in [0, 5], U_2 \in [3, 5], V_2 \in [2, 3], U_3 \in [0, 6], V_3 \in [2, 5]\), \(\text{ALL_INCOMPARABLE}((\langle U_1, V_1 \rangle), (U_2, V_2), (U_3, V_3))\).

Typical
\[
\begin{align*}
|\text{VECTOR}| &> 1 \\
|\text{VECTORS}| &> 1 \\
|\text{VECTORS}| &> |\text{VECTOR}|
\end{align*}
\]
Figure 5.25: Illustrating the incomparability of vectors $\langle 1, 18 \rangle$, $\langle 2, 16 \rangle$, $\langle 3, 13 \rangle$, $\langle 4, 11 \rangle$, $\langle 5, 10 \rangle$, $\langle 6, 9 \rangle$, $\langle 7, 7 \rangle$: first to each vector we associate a rectangle whose sizes are the components of the vector; second no matter whether we rotate a rectangle from 90° or not, one rectangle can not be included in another rectangle.

Figure 5.26: All solutions corresponding to the non ground example of the ALL_INCOMPARABLE constraint of the All solutions slot

**Symmetry**

- Items of VECTORS are permutable.

**Arg. properties**

- Contractible wrt. VECTORS.

**Usage**

- Figure 5.27 illustrates the use of the ALL_INCOMPARABLE constraint in the context of a tiling problem.

**See also**

- implies: LEX_ALLDIFFERENT.
- part of system of constraints: INCOMPARABLE.
- used in graph description: INCOMPARABLE.

**Keywords**

Arc arity  2
Arc constraint(s)  \( \text{INCOMPARABLE}(\text{vectors1}\text{.vec}, \text{vectors2}\text{.vec}) \)
Graph property(ies)  \( \text{NARC} = |\text{VECTORS}| \ast |\text{VECTORS}| - |\text{VECTORS}| \)
Graph class  
- NO LOOP
- SYMMETRIC

Graph model

The Arc constraint(s) slot uses the \text{INCOMPARABLE} constraint defined in this catalogue. Parts (A) and (B) of Figure 5.28 respectively show the initial and final graph associated with the Example slot. Since we use the \text{NARC} graph property, the arcs of the final graph are stressed in bold. The previous constraint holds since exactly \( 3 \cdot (3 - 1) = 6 \) arc constraints hold.

Figure 5.28: Initial and final graph of the \text{ALL\_INCOMPARABLE} constraint
5.13 ALL_MIN_DIST

Origin [354]

Constraint ALL_MIN_DIST(MINDIST, VARIABLES)

Synonyms MINIMUM_DISTANCE, INTER_DISTANCE.

Arguments MINDIST : int
VARIABLES : collection(var–dvar)

Restrictions MINDIST > 0
|VARIABLES| < 2 \lor MINDIST < range(VARIABLES.var)
required(VARIABLES, var)

Purpose Enforce for each pair \((\text{var}_i, \text{var}_j)\) of distinct variables of the collection VARIABLES that 
\(|\text{var}_i - \text{var}_j| \geq \text{MINDIST}\).

Example \((2, (5, 1, 9, 3))\)

The ALL_MIN_DIST constraint holds since the following expressions 
\(|5 - 1|, |5 - 9|, |5 - 3|, |1 - 9|, |1 - 3|, |9 - 3|\) are all greater than or equal to the first argument 
MINDIST = 2 of the ALL_MIN_DIST constraint.

All solutions Figure 5.29 gives all solutions to the following non ground instance of the 
ALL_MIN_DIST constraint: \(V_1 \in [0, 5], V_2 \in [3, 9], V_3 \in [5, 7], V_4 \in [2, 10], \)
ALL_MIN_DIST(3, (V1, V2, V3, V4)).

Figure 5.29: All solutions corresponding to the non ground example of the 
ALL_MIN_DIST constraint of the All solutions slot.
Typical

\[ \text{MINDIST} > 1 \]
\[ |\text{VARIABLES}| > 1 \]

Symmetries

- MINDIST can be decreased to any value \( \geq 1 \).
- Items of VARIABLES are permutable.
- Two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

Contractible wrt. VARIABLES.

Usage

The ALL_MIN_DIST constraint was initially created for handling frequency allocation problems. In [12] it is used for scheduling tasks that all have the same fixed duration in the context of air traffic management in the terminal radar control area of airports.

Remark

The ALL_MIN_DIST constraint can be modelled as a set of tasks that should not overlap. For each variable var of the VARIABLES collection we create a task \( t \) where var and MINDIST respectively correspond to the origin and the duration of \( t \).

Some solvers use in a pre-processing phase, while stating constraints of the form \( |X_i - X_j| \geq D_{ij} \) (where \( X_i \) and \( X_j \) are domain variables and \( D_{ij} \) is a constant), an algorithm for automatically extracting large cliques [97] from such inequalities in order to state ALL_MIN_DIST constraints.

Algorithm

K. Artiouchine and P. Baptiste came up with a cubic time complexity algorithm achieving bound-consistency in [12, 13] based on the adaptation of a feasibility test algorithm from M.R. Garey et al. [196]. Later on, C.-G. Quimper et al., proposed a quadratic algorithm achieving the same level of consistency in [343].

\]
Graph model

We generate a clique with a minimum distance constraint between each pair of distinct vertices and state that the number of arcs of the final graph should be equal to the number of arcs of the initial graph.

Parts (A) and (B) of Figure 5.30 respectively show the initial and final graph associated with the Example slot. The ALL_MIN_DIST constraint holds since all the arcs of the initial graph belong to the final graph: all the minimum distance constraints are satisfied.

Figure 5.30: Initial and final graph of the ALL_MIN_DIST constraint
5.14 ALLDIFFERENT

Origin [267]

Constraint ALLDIFFERENT(VARIABLES)

Synonyms ALLDIFF, ALLDISTINCT, DISTINCT, BOUND_ALLDIFFERENT, BOUND_ALLDIFF, BOUND_DISTINCT, REL.

Argument VARIABLES : collection(var–dvar)

Restriction required(VARIABLES, var)

Purpose Enforce all variables of the collection VARIABLES to take distinct values.

Example ((5, 1, 9, 3))

The ALLDIFFERENT constraint holds since all the values 5, 1, 9 and 3 are distinct.

All solutions Figure 5.31 gives all solutions to the following non ground instance of the ALLDIFFERENT constraint: $V_1 \in [2, 4]$, $V_2 \in [2, 3]$, $V_3 \in [1, 6]$, $V_4 \in [2, 5]$, $V_5 \in [2, 3]$, $V_6 \in [1, 6]$, ALLDIFFERENT($\langle V_1, V_2, V_3, V_4, V_5, V_6 \rangle$).

Figure 5.31: All solutions corresponding to the non ground example of the ALLDIFFERENT constraint of the All solutions slot

Typical $|\text{VARIABLES}| > 2$

Symmetries

- Items of VARIABLES are permutable.
- Two distinct values of VARIABLES.var can be swapped; a value of VARIABLES.var can be renamed to any unused value.
The **ALLDIFFERENT** constraint occurs in most practical problems directly or indirectly. A classical example is the *n*-queens chess puzzle problem: Place *n* queens on an *n* by *n* chessboard in such a way that no queen attacks another. Two queens attack each other if they are located on the same column, on the same row, or on the same diagonal. This can be modelled as the conjunction of three **ALLDIFFERENT** constraints. We associate to column *i* of the chessboard a domain variable *X* that gives the row number where the corresponding queen is located. The three **ALLDIFFERENT** constraints are:

- \text{alldifferent}(X_1, X_2 + 1, \ldots, X_{n} + n - 1) \text{ for the descending diagonals,}
- \text{alldifferent}(X_1, X_2, \ldots, X_{n}) \text{ for the rows,}
- \text{alldifferent}(X_1 + n - 1, X_2 + n - 2, \ldots, X_{n}) \text{ for the ascending diagonals.}

They are respectively depicted by parts (A), (C) and (D) of Figure 5.32. Figure 5.33 makes explicit the link between the two families of diagonals and the corresponding **ALLDIFFERENT** constraints. Note that this model matches the checker introduced by Gauss to test whether a permutation of row numbers is a solution or not to the 8 queens problem: first add the numbers 1 up to 8 to the permutation and check that the resulting numbers are distinct, second add the numbers 8 down to 1 and perform the same check [451, pages 165–166].

A second example taken from [15], where the bipartite graph associated with the **ALLDIFFERENT** constraint is **convex**, is a *ski assignment problem*: “a set of skiers have each specified the smallest and largest ski sizes they will accept from a given set of ski sizes”. The task is to find a ski size for each skier.
Figure 5.33: (A) For every pair of columns $i, j$ ($i < j$), given the position $X_i$ of the queen on column $i$, we respectively have from the ascending and descending diagonals that $X_j \neq X_i + (j - i)$ and $X_j \neq X_i - (j - i)$ (B) Equivalence of the two ALLDIFFERENT constraints respectively associated with the ascending and descending diagonals with the two families of disequalities (i.e., the orange and the red one) depicted in Part (A)

Examples such as Costas arrays and Golomb rulers involve one or several ALLDIFFERENT constraints on differences of variables.

Quite often, the ALLDIFFERENT constraint is also used in conjunction with several ELEMENT constraints, especially in the context of assignment problems [226, pages 372–374], or with several precedence constraints, especially in the context of symmetry breaking or scheduling problems [82]. How to handle an ALLDIFFERENT constraint together with a linear inequality constraint, where the coefficients are assumed to be fixed to one, is presented in [40].

Other examples involving several ALLDIFFERENT constraints sharing some variables can be found in the Usage slot of the K_ALLDIFFERENT constraint.

**Remark**

Even if the ALLDIFFERENT constraint did not have this form, it was specified in ALICE [266, 267] by asking for an injective correspondence $f$ between variables and values: $x \neq y \Rightarrow f(x) \neq f(y)$. From an algorithmic point of view, the algorithm for computing the cardinality of the maximum matching of a bipartite graph was not used in ALICE for checking the feasibility of the ALLDIFFERENT constraint, even though the algorithm was already known in 1976. This is because the goal of ALICE was to show that a general system could be as efficient as dedicated algorithms. For this reason the concluding part of [266] explicitly mentions that specialised algorithms should be discarded. On the one hand, many people, especially from the OR community, have complained about such a radical statement [375, page 28]. On the other hand, the motivation of such a statement stands from the fact that a truly intelligent system should not rely on black-box algorithms, but should rather be able to reconstruct them from some kind of first principles. How to achieve this is still an open question.

Some solvers use, in a pre-processing phase before stating all constraints, an algorithm for automatically extracting large cliques [97, 162] from a set of binary disequalities in order
to replace them by \textsc{AllDifferent} constraints.

W.-J. van Hoeve provides a survey about the \textsc{AllDifferent} constraint in [432].

For possible relaxation of the \textsc{AllDifferent} constraints see the \textsc{AllDifferent\_except\_0}, the \textsc{K\_AllDifferent} (i.e., \textsc{Some\_Different}), the \textsc{Soft\_AllDifferent\_ctr}, the \textsc{Soft\_AllDifferent\_var} and the \textsc{Weighted\_Partial\_AllDiff} constraints, and Figure 2.4 of Section 2.1.5.

Within the context of \textit{linear programming}, relaxations of the \textsc{AllDifferent} constraint are described in [452] and in [226, pages 362–367].

Within the context of \textit{constraint-centered search heuristics}, G. Pesant and A. Zanarini [458] have proposed several estimators for evaluating the number of solutions of an \textsc{AllDifferent} constraint (since counting the total number of maximum matchings of the corresponding variable-value graph is \#P-complete [424]). Faster, but less accurate estimators, based on upper bounds of the number of solutions were proposed three years later by the same authors [459].

Given \(n\) variables taking their values within the interval \([1, n]\), the total number of solutions to the corresponding \textsc{AllDifferent} constraint corresponds to the sequence A000142 of the On-Line Encyclopaedia of Integer Sequences [403].

\textbf{Algorithm}

The first complete filtering algorithm was independently found by M.-C. Costa [132] and J.-C. Régine [351]. This algorithm is based on a corollary of C. Berge that characterises the edges of a graph that belong to a maximum matching but not to all [63, page 120].\footnote{A similar result is in fact given in [320].} Similarly, Dulmage-Mendelsohn decomposition [157] was also used recently by [138, 139] to characterise such edges and prune the corresponding variables both for the \textsc{AllDifferent} constraint and for other constraints like \textsc{AllDifferent\_except\_0}, \textsc{Correspondence}, \textsc{Inverse}, \textsc{Same}, \textsc{Used\_By}, \textsc{Global\_Cardinality\_Low\_Up}, \textsc{Soft\_AllDifferent\_var}, \textsc{Soft\_Same\_var}, \textsc{Soft\_Used\_By\_var}.\footnote{Note that Dulmage-Mendelsohn decomposition [157] was also used in the context of geometric constraints [5, 90] for decomposing systems of equations.}

Assuming that all variables have no holes in their domains, M. Leconte came up with a filtering algorithm [270] based on edge finding. A first \textit{bound-consistency} algorithm was proposed by Bleuzen-Guernalec et al. [85]. Later on, two different approaches were used to design \textit{bound-consistency} algorithms. Both approaches model the constraint as a bipartite graph. The first identifies \textit{Hall intervals} in this graph [335, 277] and the second applies the same algorithm that is used to compute \textit{arc-consistency}, but achieves a speedup by exploiting the simpler structure [205] of the graph [292]. Ian P. Gent et al. discuss in [200] implementations issues behind the complete filtering algorithm and in particular the computation of the strongly connected components of the residual graph (i.e., a graph constructed from a maximum variable-value matching and from the possible values of the variables of the \textsc{AllDifferent} constraint), which appears to be the main \textit{bottleneck} in practice. Figures 2.1 and 2.2 of Section 2.1.3 illustrate the filtering of the \textsc{AllDifferent} constraint with respect to \textit{arc-consistency} and \textit{bound-consistency}. The leftmost part of Figure 3.29 illustrates a flow model for the \textsc{AllDifferent} constraint where there is a one-to-one correspondence between feasible flows in the flow model and solutions to the \textsc{AllDifferent} constraint.

From a worst case complexity point of view, assuming that \(n\) is the number of variables and \(m\) the sum of the domains sizes, we have the following complexity results:
• Complete filtering is achieved in $O(m\sqrt{n})$ by Régin’s algorithm [351].

• Range consistency is done in $O(n^2)$ by Leconte’s algorithm [270].

• **Bound-consistency** is performed in $O(n \log n)$ in [335, 292, 277]. If sort can be achieved in linear time, typically when the ALLDIFFERENT constraint encodes a permutation, the worst case complexity of the algorithms described in [292, 277] goes down to $O(n)$.

Within the context of explanations [239], the explanation of the filtering algorithm that achieves arc-consistency for the ALLDIFFERENT constraint is described in [370], pages 60–61. Given the residual graph (i.e., a graph constructed from a maximum variable-value matching and from the possible values of the variables of the ALLDIFFERENT constraint), the removal of an arc starting from a vertex belonging to a strongly connected component $C_1$ to a distinct strongly connected component $C_2$ is explained by all missing arcs starting from a descendant component of $C_2$ and ending in an ancestor component of $C_1$ (i.e., since the addition of any of these missing arcs would merge the strongly connected components $C_1$ and $C_2$). Let us illustrate this on a concrete example. For this purpose assume we have the following variables and the values that can potentially be assigned to each of them, $A \in \{1, 2\}$, $B \in \{1, 2\}$, $C \in \{2, 3, 4, 6\}$, $D \in \{3, 4\}$, $E \in \{5, 6\}$, $F \in \{5, 6\}$, $G \in \{6, 7, 8\}$, $H \in \{6, 7, 8\}$. Figure 5.34 represents the residual graph associated with the maximum matching corresponding to the assignment $A = 1$, $B = 2$, $C = 3$, $D = 4$, $E = 5$, $F = 6$, $G = 7$, $H = 8$. It has four strongly connected components containing respectively vertices $\{A, B, 1, 2\}$, $\{C, D, 3, 4\}$, $\{E, F, 5, 6\}$ and $\{G, H, 7, 8\}$. Arcs that are between strongly connected components correspond to values that can be removed:

• The removal of value 2 from variable $C$ is explained by the absence of the arcs corresponding to the assignments $A = 3$, $A = 4$, $B = 3$ and $B = 4$ (since adding any of these missing arcs would merge the blue and the pink strongly connected components containing the vertices corresponding to value 2 and variable $C$).

• The removal of value 6 from variable $C$ is explained by the absence of the arcs corresponding to the assignments $E = 3$, $E = 4$, $F = 3$ and $F = 4$. Again adding the corresponding arcs would merge the two strongly connected components containing the vertices corresponding to value 6 and variable $C$.

• The removal of value 6 from variable $G$ is explained by the absence of the arcs corresponding to the assignments $E = 7$, $E = 8$, $F = 7$ and $F = 8$.

• The removal of value 6 from variable $H$ is explained by the absence of the arcs corresponding to the assignments $E = 7$, $E = 8$, $F = 7$ and $F = 8$.

An additional example for illustrating the generation of explanations for the ALLDIFFERENT constraint when there are more values than variables is provided by Figure 2.3 of Section 2.1.4.

After applying bound-consistency the following property holds for all variables of an ALLDIFFERENT constraint. Given a Hall interval $[l, u]$, any variable $V$ whose range $[\underline{V}, \overline{V}]$ intersects $[l, u]$ without being included in $[l, u]$ has its minimum value $\underline{V}$ (respectively maximum value $\overline{V}$) that is located before (respectively after) the Hall interval (i.e., $\underline{V} < l \leq u < \overline{V}$).

---

3In this context the total number of values that can be assigned to the variables of the ALLDIFFERENT constraint is equal to the number of variables. Under this assumption sorting the variables on their minimum or maximum values can be achieved in linear time.
The ALLDIFFERENT constraint is entailed if and only if there is no value \( v \) that can be assigned two distinct variables of the VARIABLES collection (i.e., the intersection of the two sets of potential values of any pair of variables is empty).

**Reformulation**

The ALLDIFFERENT constraint can be reformulated into a set of disequalities constraints. This model neither preserves bound-consistency nor arc-consistency:

- On the one hand a model, involving linear constraints, preserving bound-consistency was introduced in [78]. For each potential interval \([l, u]\) of consecutive values this model uses \(|\text{VARIABLES}|\) 0-1 variables \( B_{1,l,u}, B_{2,l,u}, \ldots, B_{|\text{VARIABLES}|,l,u} \) for modelling that each variable of the collection VARIABLES is assigned a value within interval \([l, u]\) (i.e., \( \forall i \in [1, |\text{VARIABLES}|] : B_{i,l,u} \iff \text{VARIABLES}[i].\text{var} \in [l, u] \)) and an inequality constraint for enforcing the condition that the sum of the corresponding 0-1 variables is less than or equal to the size \( u - l + 1 \) of the corresponding interval (i.e. \( B_{1,l,u} + B_{2,l,u} + \cdots + B_{|\text{VARIABLES}|,l,u} \leq u - l + 1 \)).

- On the other hand, it was shown in [81] that there is no polynomial sized decomposition that preserves arc-consistency.

Finally the ALLDIFFERENT(VARIABLES) constraint can also be reformulated as the conjunction \( \text{SORT}(\text{VARIABLES}, \text{SORTED VARIABLES}) \land \text{STRICTLY_INCREASING}(\text{SORTED VARIABLES}) \). Unlike the naive reformulation, i.e., a DISEQUALITY constraint between each pair of variables, the SORT-based reformulation is linear in space.

---

\( ^4 \)How to encode the reified constraint \( B_{i,l,u} \iff \text{VARIABLES}[i].\text{var} \in [l, u] \) with linear constraints is described in the Reformulation slot of the IN_INTERVAL_REIFIED constraint.

**Graph model**

We generate a *clique* with an *equality* constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed one.

Parts (A) and (B) of Figure 5.35 respectively show the initial and final graph associated with the *Example* slot. Since we use the MAX_NSCC graph property we show one of the largest strongly connected component of the final graph. The ALLDIFFERENT holds since all the strongly connected components have at most one vertex: a value is used at most once.

![Graph model](image)

**Figure 5.35**: Initial and final graph of the ALLDIFFERENT constraint
Figure 5.36 depicts the automaton associated with the `ALLDIFFERENT` constraint. To each item of the collection `VARIABLES` corresponds a signature variable $S_i$ that is equal to 1. The automaton counts the number of occurrences of each value and finally imposes that each value is taken at most one time.

**Quiz**

**EXERCISE 1 (checking whether a ground instance holds or not)**

A. Does the constraint `ALLDIFFERENT((5, 1, 4, 8, 1))` hold?

B. Does the constraint `ALLDIFFERENT((8, 2, 4, 3))` hold?

C. Does the constraint `ALLDIFFERENT((0))` hold?

*Hint: go back to the definition of `ALLDIFFERENT`.

**EXERCISE 2 (finding all solutions)**

Give all the solutions to the constraint:

$$\begin{cases} V_1 \in [3, 5], & V_2 \in [3, 4], & V_3 \in [2, 7], \\ V_4 \in [3, 4], & V_5 \in [2, 7], \\ \text{ALLDIFFERENT}((V_1, V_2, V_3, V_4, V_5)) \end{cases}$$

*Hint: identify infeasible values, enumerate solutions in lexicographic order.

**EXERCISE 3 (finding all solutions)**

Give all the solutions to the constraint:

$$\begin{cases} V_1 \in [4, 6], & V_2 \in [1, 3], & V_3 \in [1, 4], & V_4 \in [1, 2], \\ V_5 \in [4, 7], & V_6 \in [4, 6], & V_7 \in [1, 2], \\ \text{ALLDIFFERENT}((V_1, V_2, V_3, V_4, V_5, V_6, V_7)) \end{cases}$$

*Hint: focus on variables with smallest domain first, identify Hall intervals for finding infeasible values, enumerate solutions in lexicographic order.
EXERCISE 4 (finding all solutions)

Give all the solutions to the constraint:

\[
\begin{align*}
V_1 &\in \{1, 3\}, & V_2 &\in \{1, 2, 3, 4\}, \\
V_3 &\in \{1, 5\}, & V_4 &\in \{1, 2, 3, 4, 5, 6\}, \\
V_5 &\in \{3, 5\},
\end{align*}
\]

\[\text{ALLDIFFERENT}(\langle V_1, V_2, V_3, V_4, V_5 \rangle).\]

"Hint: focus on variables with smallest domain first, identify Hall sets for finding infeasible values, enumerate solutions in lexicographic order.

EXERCISE 5 (identifying infeasible values)

Identify all variable-value pairs \((V_i, \text{val})\) \((1 \leq i \leq 6)\), such that the following constraint has no solution when variable \(V_i\) is assigned value \(\text{val}\):

\[
\begin{align*}
V_1 &\in \{1, 2, 4\}, & V_2 &\in \{1, 2, 3, 4, 6\}, & V_3 &\in \{1, 2, 6\}, \\
V_4 &\in [1, 6], & V_5 &\in \{1, 4, 6\}, & V_6 &\in [2, 4, 6],
\end{align*}
\]

\[\text{ALLDIFFERENT}(\langle V_1, V_2, V_3, V_4, V_5, V_6 \rangle).\]

"Hint: focus on variables with smallest domain first, identify Hall sets for finding infeasible values.

EXERCISE 6 (identifying infeasible values and counting)

A. Identify six variable-value pairs \((V_i, \text{val})\) \((1 \leq i \leq 9)\), such that the following conjunction of constraints has no solution when variable \(V_i\) is assigned value \(\text{val}\).

\[
\begin{align*}
V_1 &\in [1, 7], & V_2 &\in [1, 7], & V_3 &\in [1, 7], \\
V_4 &\in [1, 4], & V_5 &\in [1, 4], & V_6 &\in [1, 4], \\
V_7 &\in [3, 6], & V_8 &\in [3, 6], & V_9 &\in [3, 6], \\
\text{ALLDIFFERENT}(\langle V_1, V_2, V_3, V_4, V_5, V_6 \rangle), & \text{ALLDIFFERENT}(\langle V_1, V_2, V_3, V_7, V_8, V_9 \rangle).
\end{align*}
\]

B. Describe concisely the structure of the set of solutions and derive the total number of solutions.

"Hint: group together variables that belong to the same set of constraints and reason on the number of distinct values assigned to such groups.
EXERCISE 7 (variable-based degree of violation)\textsuperscript{a,b}

Compute the variable-based degree of violation\textsuperscript{b} of the following constraints:

A. \textsc{AllDifferent}((2, 2, 2, 2)),
B. \textsc{AllDifferent}((3, 1, 5, 2, 7)),
C. \textsc{AllDifferent}((5, 5, 0, 5, 5, 0, 7)).

\textsuperscript{a}Hint: focus on the groups of variables that are assigned the same value.

\textsuperscript{b}Given a constraint for which all variables are fixed, the \textit{variable-based degree of violation} is the minimum number of variables to assign differently in order to satisfy the constraint.

---

EXERCISE 8 (preventing conflict around the table)\textsuperscript{a,c}

Provide a concise and efficient model for the following problem. Given a set \( M \) of \( n \) men, a set \( W \) of \( n \) women, a set of pairs \( C \) where each pair \((m, w) \in C\) represents a conflict between the man \( m \) (\( m \in M \)) and the woman \( w \) (\( w \in W \)), a rectangular table, the goal is to place on one side of the table all the \( n \) men and on the opposite side all the \( n \) women in such a way that two persons that are in conflict do not sit face to face.

\textsuperscript{a}Adapted from the 2011 constraint programming exam at Polytechnique, C. D"urr.

\textsuperscript{c}Hint: break some symmetry of the problem.
EXERCISE 9 (identifying equalities from a clique of disequalities)

[CONTEXT] Given an undirected graph $G = (V, E)$, colour each vertex $v \in V$ in such a way that (1) two vertices that are linked by an edge of the set of edges $E$ are not assigned the same colour, and (2) no more than $m$ distinct colours are used to colour all the vertices of $G$. The goal of the exercise is to find out necessary conditions for this problem that go beyond the cardinality of a (maximum) clique.

A. [IDENTIFYING PAIRS OF VERTICES THAT SHOULD BE ASSIGNED THE SAME COLOUR]

(a) Given the vertices of the following graph $G$ to colour with at most three distinct colours, explain why vertices $v_1$ and $v_3$ should be assigned the same colour.

(b) For graph $G$ provide all pairs of vertices that should be assigned the same colour if no more than three distinct colours have to be used.

B. [GENERALISING THE NECESSARY CONDITION]

Given a clique of $n$ vertices $C$ of the graph $G$, let $V_C$ denote the set of vertices that do not belong to $C$ and that are all connected to all vertices of $C$. Assuming that one should use at most $m$ distinct colours provide a necessary condition on the set $V_C$.

*Hint: restrict extra values wrt a clique of disequalities.*

EXERCISE 10 (8-queens: unfeasibility of a partial solution)

Consider the 8-queens problem where we start filling the chessboard in a systematic way: we place a first queen in a1 and a second queen in b3. Prove that it is not possible to extend this partial assignment to a complete solution.

*Hint: consider each of the 4 remaining positions on column c; extract information from the conjunction of the three ALLDIFFERENT constraints that allows the modelling of the $n$-queens problem.*

*Place 8 queens on an 8 by 8 chessboard in such a way that no queen attacks another. Two queens attack each other if they are located on the same column, on the same row, or on the same diagonal.*
SOLUTION TO EXERCISE 1

A. No, since value 1 is used twice.
B. Yes, since all values 8, 2, 4 and 3 are distinct.
C. Yes, since value 0 is only used once.

SOLUTION TO EXERCISE 2

Values 3 and 4 have to be assigned to the two variables $V_2$ and $V_4$. Consequently, $V_1$, $V_3$ and $V_5$ are different from 3 and 4.

Values 3, 4 and 5 have to be assigned to $V_1$, $V_2$ and $V_4$. Value 6 is directly mentioned in the constraint. Consequently the two remaining variables $V_3$ and $V_5$ can only be assigned values 2 and 7.
SOLUTION TO EXERCISE 3

Let us reorder the variables by increasing minimum value, and by increasing maximum value in case of tie, for example, $V_4, V_7, V_2, V_3, V_1, V_6, V_5$.

1. Since values 1 and 2 have to be assigned to $V_4$ and $V_7$ (interval $[1, 2]$ is a Hall interval), they cannot be assigned to the other variables and consequently $V_2$ is fixed to 3.
2. Since $V_2$ is fixed to 3, $V_3$ is fixed to 4.
3. Since $V_3$ is fixed to 4, $V_1$ and $V_6$ can only be assigned values 5 or 6 (interval $[5, 6]$ is a Hall interval).
4. Since values 5 and 6 cannot be assigned to $V_5$, $V_5$ is fixed to 7.

"Given a set of domain variables, a Hall interval is an interval of values $[\ell, u]$ such that there are $u - \ell + 1$ variables whose domains are contained in $[\ell, u]$."

(a) $\langle v_1, v_2, v_3, v_4, v_5, v_6, v_7 \rangle$
(b) $\langle 5, 3, 4, 1, 7, 6, 2 \rangle$
(c) $\langle 5, 3, 4, 2, 7, 6, 1 \rangle$
(d) $\langle 6, 3, 4, 1, 7, 5, 2 \rangle$
(e) $\langle 6, 3, 4, 2, 7, 5, 1 \rangle$

SOLUTION TO EXERCISE 4

Let us reorder the variables by increasing domain size, increasing minimum, and increasing maximum in case of tie, i.e., $V_1$, $V_3$, $V_5$, $V_2$, $V_4$. Since values 1, 3 and 5 have to be assigned to $V_1$, $V_3$ and $V_5$ ($\{1, 3, 5\}$ is a Hall set), they cannot be assigned to the other variables and consequently values 1, 3 and 5 are removed from $V_2$ and $V_4$ (see 1).

*Given a set of domain variables, a Hall set is a set of values $\mathcal{H}$ such that there are $|\mathcal{H}|$ variables whose domains are contained in $\mathcal{H}$. 
SOLUTION TO EXERCISE 5

1. In part (A) we first identify the Hall set $H_1 = \{1, 2, 4, 6\}$ which contains the domains of variables $V_1, V_3, V_5$ and $V_6$.

2. In part (B) we remove values 1, 2, 4 and 6 from those variables for which the domain is not included within the Hall set $H_1$, namely $V_2$ and $V_4$, see $\times$.

3. After the previous filtering we identify in part (B) a new Hall set $H_2 = \{3\}$ which contains the domain of $V_2$.

4. Finally in part (C) we remove value 3 from those variables for which the domain is not included within the Hall set $H_2$, namely $V_4$, see $\times$.

---

*Given a set of domain variables, a Hall set is a set of values $H$ such that there are $|H|$ variables whose domains are contained in $H$.*
SOLUTION TO EXERCISE 6

A. (i) The cardinality of the union of the domains of $V_1, V_2, \ldots, V_9$ is equal to 7. Since $V_1, V_2$ and $V_3$ will be assigned 3 distinct values, the remaining variables $V_4, V_5, \ldots, V_9$ should not be assigned more than $7 - 3 = 4$ distinct values.

(ii) $V_4, V_5, \ldots, V_9$ can be partitioned in two sets $\{V_4, V_5, V_6\}$ and $\{V_7, V_8, V_9\}$ which respectively correspond to the variables that only belong to the first and to the second ALLDIFFERENT. The first set will be assigned distinct values in interval $[1, 4]$, while the second set will be assigned distinct values in interval $[3, 6]$.

(iii) Since $V_4, V_5, \ldots, V_9$ should not be assigned more than 4 distinct values, the two values 3 and 4 that belong both to $[1, 4]$ and $[3, 6]$ should be both assigned to $\{V_4, V_5, V_6\}$ and to $\{V_7, V_8, V_9\}$. Consequently values 3 and 4 cannot be assigned to variables $V_1, V_2$ and $V_3$.

B. As illustrated by the next figure, we have four families of solutions ①, ②, ③ and ④ where the three sets of variables $\{V_1, V_2, V_3\}, \{V_4, V_5, V_6\}$ and $\{V_7, V_8, V_9\}$ are assigned values from three distinct set of values. This leads to a total number of solutions $4 \cdot 3! \cdot 3! \cdot 3! = 864$. 

\[
\begin{align*}
&\{V_1, V_2, V_3\} \quad \{V_4, V_5, V_6\} \quad \{V_7, V_8, V_9\} \\
&\{1, 5, 7\} \quad \{2, 3, 4\} \quad \{3, 4, 6\} \\
&\{V_1, V_2, V_3\} \quad \{V_4, V_5, V_6\} \quad \{V_7, V_8, V_9\} \\
&\{1, 6, 7\} \quad \{2, 3, 4\} \quad \{3, 4, 5\} \\
&\{V_1, V_2, V_3\} \quad \{V_4, V_5, V_6\} \quad \{V_7, V_8, V_9\} \\
&\{2, 5, 7\} \quad \{1, 3, 4\} \quad \{3, 4, 6\} \\
&\{V_1, V_2, V_3\} \quad \{V_4, V_5, V_6\} \quad \{V_7, V_8, V_9\} \\
&\{2, 6, 7\} \quad \{1, 3, 4\} \quad \{3, 4, 5\}
\end{align*}
\]
SOLUTION TO EXERCISE 7

A. The degree of violation is equal to 3 since at least three occurrences of value 2 (e.g., the three in red) out of the four occurrences of value 2 need to be assigned differently (e.g., 3, 4, 5 in blue) in order to obtain a solution.

\[\text{ALLDIFFERENT}(\langle 2, 2, 2 \rangle)\]

B. The degree of violation is equal to 0 since the constraint holds, i.e., no value needs to be assigned differently.

C. The degree of violation is equal to 4 since at least three occurrences of value 5 and one occurrence of value 0 (e.g., the three 5 and the 0 in red) need to be assigned differently (e.g., 1, 3, 6, 4 in blue) in order to obtain a solution.

\[\text{ALLDIFFERENT}(\langle 5, 5, 0, 5, 0, 7 \rangle)\]

SOLUTION TO EXERCISE 8

Without loss of generality let us assume that the sets \(\mathcal{M}\) and \(\mathcal{W}\) are both equal to \(\{1, 2, \ldots, n\}\). We associate to each woman \(w\) in \(\mathcal{W}\) a variable \(F_w\) providing the man which sits in front of \(w\).\(^3\)

1. To prevent any conflict, the initial domain of each variable \(F_w\) (\(w \in \mathcal{W}\)) is set to all the men of \(\mathcal{M}\) that are not in conflict with woman \(w\), i.e., the men \(m \in \mathcal{M}\) such that \((m, w) \notin \mathcal{C}\).

2. To enforce the fact that each woman can only sit in front of a single man we enforce an \(\text{ALLDIFFERENT}(\{F_1, F_2, \ldots, F_n\})\) constraint.

\(^3\)Note that this model does not introduce variables for the men, i.e., each man is a value and each woman a variable. The model also eliminates some symmetry, i.e., it does not care where a woman sits.

AN INSTANCE

\(\mathcal{W} = \{\text{Bea, Lea, Lili}\}\)
\(\mathcal{M} = \{\text{Leo, Luis, Tom}\}\)
\(\mathcal{C} = \{(\text{Luis, Bea}), (\text{Tom, Bea}), (\text{Luis, Lea}), (\text{Leo, Lili})\}\)

A SOLUTION

(red edges correspond to conflicts)

Leo Luis Tom
Bea Lili Lea
SOLUTION TO EXERCISE 9

A. [IDENTIFYING PAIRS OF VERTICES THAT SHOULD BE ASSIGNED THE SAME COLOUR]

(a) Since we have to use at most 3 distinct colours, since \( v_2 \) and \( v_5 \) use two distinct colours, and since \( v_1 \) and \( v_3 \) are both linked to \( v_2 \) and \( v_5 \), we infer that \( v_1 \) and \( v_3 \) both have to use the third and last available colour.

(b) For a similar reason:

- \( v_2 \) and \( v_4 \) use the same colour since they are both linked to \( v_1 \) and \( v_5 \).
- \( v_2 \) and \( v_6 \) use the same colour since they are both linked to \( v_3 \) and \( v_5 \).

B. [GENERALISING THE NECESSARY CONDITION]

Since we should use at most \( m \) distinct colours and since all vertices of the set \( V_C \) are linked to all vertices of the clique \( C \) of \( n \) vertices, the set \( V_C \) should use at most \( m - n \) distinct colours. In the previous setting we had \( m = 3 \) and \( n = 2 \), i.e., one unique colour for all elements of \( V_C \). The figure on the right illustrates the constraint generated wrt the clique \( C = \{ v_2, v_5 \} \).
SOLUTION TO EXERCISE 10

We do case reasoning depending on where we place the queen on the third column. After placing the third queen we mark all cells that are located on the same column, row, or diagonal of one of the three already placed queens. Then we focus on the rows or columns for which no more than three consecutive cells are still empty since it allows the conjunction of constraints to prune the next row or column.

- [PLACING A QUEEN ON \(c_5\)]
  After marking all cells that are located on a same column, row, or diagonal than \(a_1, b_3,\) and \(c_5\) we get the chessboard shown on the right.

Then we focus on row 8, which contains only two consecutive free cells. Since the eighth row must contain one queen this queen will be located at position \(d_8\) or \(e_8\). In both cases the cell \(d_7\) will be forbidden. By performing the same reasoning on the sixth row we also find out that the cell \(h_7\) is forbidden. As a result no queen can be placed on row 7.

- [MOVING THE THIRD QUEEN FROM \(c_5\) TO \(c_6\)]
  After marking all cells that are located on a same column, row, or diagonal than \(a_1, b_3,\) and \(c_6\) we get the chessboard shown on the right.

We focus on row 5, which contains only three consecutive free cells, see (D). Since row 5 must contain a queen, this queen will be located at position \(f_5, g_5,\) or \(h_5\). In all three cases the cell \(g_4\) will be forbidden. Similarly by considering the fourth row, see (E), we find out that no queen can be placed on \(g_5\). As a result no queen can be placed on column \(g\).
SOLUTION TO EXERCISE 10 (continued)

- **[MOVING THE THIRD QUEEN FROM c6 TO c7]**
  After marking all cells that are located on a same column, row, or diagonal than a1, b3, and c7 we get the chessboard shown in (F).
  Since on column d only position d2 is free a queen $\mathfrak{1}$ is placed on d2 and we mark with small red crosses the new forbidden positions, see (G). Then on row 6 only position g6 is free. Consequently a queen $\mathfrak{2}$ is placed on g6, which forbids all remaining free positions on row 5.

- **[MOVING THE THIRD QUEEN FROM c7 TO c8]**
  After marking all cells that are located on a same column, row, or diagonal than a1, b3, and c8 we get the chessboard shown in (H).
  Then we focus on row 5, see (I), which contains only two consecutive free cells. Since the fifth row must contain one queen this queen will be located at position g5 or h5. In both cases the cell g6 is forbidden.
  By performing the same reasoning we also find out that cell h6 is forbidden. Since on row 6 only position d6 is free, a queen $\mathfrak{1}$ is placed on d6 and we mark with small blue crosses the new forbidden positions. Then on column f only position f2 is free. Consequently a queen $\mathfrak{2}$ is placed on f2 and we mark with small green crosses the new forbidden positions. Now row 7 and column e have only one free cell, namely h7 and e4 which are located on the same diagonal. Consequently, we cannot place the last two queens on e4 and h7. Hence the first two queens cannot be placed on a1 and b3.
5.15 ALLDIFFERENT_BETWEEN_SETS

**Description**

**Origin**

ILOG

**Constraint**

ALLDIFFERENT_BETWEEN_SETS(VARIABLES)

**Synonyms**

ALL_NULL_INTERSECT, ALLDIFF_BETWEEN_SETS, ALLDISTINCT_BETWEEN_SETS, ALLDIFF_ON_SETS, ALLDISTINCT_ON_SETS, ALLDIFFERENT_ON_SETS.

**Argument**

VARIABLES : collection(var−svar)

**Restriction**

required(VARIABLES, var)

**Purpose**

Enforce all sets of the collection VARIABLES to be distinct.

**Example**

\[ ((\text{var} \− \{3,5\}, \text{var} \− \emptyset, \text{var} \− \{3\}, \text{var} \− \{3,5,7\})) \]

The ALLDIFFERENT_BETWEEN_SETS constraint holds since all the sets \{3,5\}, \emptyset, \{3\} and \{3,5,7\} are distinct.

**Typical**

|VARIABLES| > 2

**Symmetry**

Items of VARIABLES are permutable.

**Arg. properties**

Contractible wrt. VARIABLES.

**Usage**

This constraint was available in some configuration library offered by Ilog.

**Algorithm**

A filtering algorithm for the ALLDIFFERENT_BETWEEN_SETS is proposed by C.-G. Quimper and T. Walsh in [346] and a longer version is available in [347] and in [348].

**See also**

- common keyword: LINK_SET_TOBOOLEANS (constraint involving set variables).
- specialisation: ALLDIFFERENT (set variable replaced by variable).
- used in graph description: EQ_SET.

**Keywords**

- characteristic of a constraint: all different, disequality.
- constraint arguments: constraint involving set variables.
- filtering: bipartite matching.
- final graph structure: one_suc.
We generate a *clique* with binary *set equalities* constraints between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed 1.

Parts (A) and (B) of Figure 5.37 respectively show the initial and final graph associated with the Example slot. Since we use the MAX_NSCC graph property we show one of the largest strongly connected components of the final graph. The ALLDIFFERENT_BETWEEN_SETS holds since all the strongly connected components have at most one vertex.
5.16 ALLDIFFERENT_CONSECUTIVE_VALUES

Origin
Derived from ALLDIFFERENT.

Constraint
ALLDIFFERENT_CONSECUTIVE_VALUES(VARIABLES)

Argument
VARIABLES : collection(var−dvar)

Restrictions
required(VARIABLES, var)
ALLDIFFERENT(VARIABLES)

Purpose
Enforce (1) all variables of the collection VARIABLES to take distinct values and (2) constraint the difference between the largest and the smallest values of the VARIABLES collection to be equal to the number of variables minus one (i.e., there is no holes at all within the used values).

Example
((5, 4, 3, 6))

The ALLDIFFERENT_CONSECUTIVE_VALUES constraint holds since (1) all the values 5, 4, 3 and 6 are distinct and since (2) all values between value 3 and value 6 are actually used.

All solutions
Figure 5.38 gives all solutions to the following non ground instance of the ALLDIFFERENT_CONSECUTIVE_VALUES constraint: \( V_1 \in \{0, 1, 3, 4, 5, 6, 7, 8\}, V_2 \in [4, 5], V_3 \in [3, 4], V_4 \in [0, 7], V_5 \in [3, 4], \) ALLDIFFERENT_CONSECUTIVE_VALUES((V_1, V_2, V_3, V_4, V_5)).

\[
\begin{align*}
\circ & \ (1, 5, 3, 2, 4) \\
\bullet & \ (1, 5, 4, 2, 3) \\
\bullet & \ (6, 5, 3, 2, 4) \\
\bullet & \ (6, 5, 3, 7, 4) \\
\bullet & \ (6, 5, 4, 2, 3) \\
\bullet & \ (6, 5, 4, 7, 3) \\
\bullet & \ (7, 5, 3, 6, 4) \\
\bullet & \ (7, 5, 4, 6, 3)
\end{align*}
\]

Figure 5.38: All solutions corresponding to the non ground example of the ALLDIFFERENT_CONSECUTIVE_VALUES constraint of the All solutions slot, where the smallest and largest values are respectively coloured in orange and red.

Typical
| VARIABLES | > 2

Symmetries
- Items of VARIABLES are permutable.
- Two distinct values of VARIABLES.var can be swapped.
- One and the same constant can be added to the var attribute of all items of VARIABLES.
Counting

5.17 ALLDIFFERENT_CST

Origin  CHIP
Constraint  ALLDIFFERENT_CST(VARIABLES)
Synonyms  ALLDIFF.CST, ALLDISTINCT.CST.
Argument  VARIABLES : collection(var−dvar,cst−int)
Restriction  required(VARIABLES,[var,cst])
Purpose  For all pairs of items (VARIABLES[i],VARIABLES[j]) (i ≠ j) of the collection VARIABLES enforce VARIABLES[i].var + VARIABLES[i].cst ≠ VARIABLES[j].var + VARIABLES[j].cst.

Example

\[
\begin{pmatrix}
\text{var } - 5 & \text{cst } - 0, \\
\text{var } - 1 & \text{cst } - 1, \\
\text{var } - 9 & \text{cst } - 0, \\
\text{var } - 3 & \text{cst } - 4
\end{pmatrix}
\]

The ALLDIFFERENT_CST constraint holds since all the expressions 5 + 0 = 5, 1 + 1 = 2, 9 + 0 = 9 and 3 + 4 = 7 correspond to distinct values.

All solutions

Figure 5.39 gives all solutions to the following non ground instance of the ALLDIFFERENT_CST constraint: \(V_1 \in [0,2], V_2 \in [4,5], V_3 = 4, V_4 \in [0,1]\), ALLDIFFERENT_CST((⟨V_1,0⟩,⟨V_2,1⟩,⟨V_3,2⟩,⟨V_4,3⟩)).

\[
\begin{align*}
\text{(i) } & \langle 0+0, 4+1, 4+2, 0+3 \rangle \\
\text{(ii) } & \langle 0+0, 4+1, 4+2, 1+3 \rangle \\
\text{(iii) } & \langle 1+0, 4+1, 4+2, 0+3 \rangle \\
\text{(iv) } & \langle 1+0, 4+1, 4+2, 1+3 \rangle \\
\text{(v) } & \langle 2+0, 4+1, 4+2, 0+3 \rangle \\
\text{(vi) } & \langle 2+0, 4+1, 4+2, 1+3 \rangle
\end{align*}
\]

Figure 5.39: All solutions corresponding to the non ground example of the ALLDIFFERENT_CST constraint of the All solutions slot

Typical

\[
\begin{align*}
|\text{VARIABLES}| & > 2 \\
\text{range}(&\text{VARIABLES.var}) & > 1 \\
2\text{range}(&\text{VARIABLES.var}) & < 3 \times |\text{VARIABLES}| \\
\text{range}(&\text{VARIABLES.cst}) & > 1
\end{align*}
\]
### Symmetries
- Items of `VARIABLES` are permutable.
- Attributes of `VARIABLES` are permutable w.r.t. permutation \((\text{var}, \text{cst})\) \((\text{permutation not necessarily applied to all items})\).
- One and the same constant can be added to the `var` attribute of all items of `VARIABLES`.
- One and the same constant can be added to the `cst` attribute of all items of `VARIABLES`.

### Arg. properties
Contractible wrt. `VARIABLES`.

### Usage
The `ALLDIFFERENT_CST` constraint was originally introduced in CHIP in order to express the \(n\)-queen problem with 3 global constraints (see the Usage slot of the `ALLDIFFERENT` constraint).

### Algorithm
See the filtering algorithms of the `ALLDIFFERENT` constraint.

### Systems
LINEAR in Gecode.

We generate a *clique* with an *equality* constraint between each pair of vertices (including a vertex and itself) and state that the *size* of the largest strongly connected component should not exceed one.

Parts (A) and (B) of Figure 5.40 respectively show the initial and final graph associated with the **Example** slot. Since we use the **MAX_NSCC** graph property we show one of the largest strongly connected components of the final graph. The **ALLDIFFERENT_CST** holds since all the strongly connected components have at most one vertex: a value is used at most once.

![Graph model](image-url)
5.18 ALLDIFFERENT_EXCEPT_0

Origin
Derived from ALLDIFFERENT.

Constraint
ALLDIFFERENT_EXCEPT_0(VARIABLES)

Synonyms
ALLDIFF_EXCEPT_0, ALLDISTINCT_EXCEPT_0.

Argument
VARIABLES : collection(var-dvar)

Restriction
required(VARIABLES,var)

Purpose
Enforce all variables of the collection VARIABLES to take distinct values, except those variables that are assigned value 0.

Example
\( ((5, 0, 1, 9, 3)) \)

The ALLDIFFERENT_EXCEPT_0 constraint holds since all the values (that are different from 0) 5, 1, 9 and 3 are distinct.

All solutions
Figure 5.41 gives all solutions to the following non ground instance of the ALLDIFFERENT_EXCEPT_0 constraint: \( V_1 \in [0, 4], V_2 \in [1, 2], V_3 \in [1, 2], V_4 \in [0, 1], \) ALLDIFFERENT_EXCEPT_0(\( \langle V_1, V_2, V_3, V_4 \rangle \)).

\[ \begin{align*}
1 & \langle (0, 1, 2, 0) \rangle \\
2 & \langle (0, 2, 1, 0) \rangle \\
3 & \langle (3, 1, 2, 0) \rangle \\
4 & \langle (3, 2, 1, 0) \rangle \\
5 & \langle (4, 1, 2, 0) \rangle \\
6 & \langle (4, 2, 1, 0) \rangle
\end{align*} \]

Figure 5.41: All solutions corresponding to the non ground example of the ALLDIFFERENT_EXCEPT_0 constraint of the All solutions slot

Typical
\(|VARIABLES| > 2 \\
\text{ATLEAST}(2, VARIABLES, 0) \\
\text{range}(VARIABLES,var) > 1 \)

Typical model
\( \text{nval}(VARIABLES,var) > 2 \)

Symmetries
- Items of VARIABLES are permutable.
- Two distinct values of VARIABLES.var that are both different from 0 can be swapped; a value of VARIABLES.var that is different from 0 can be renamed to any unused value that is also different from 0.
Arg. properties  
Contractible wrt. VARIABLES.

Usage  
Quite often it appears that, for some modelling reason, you create a joker value. You do not want that normal constraints hold for variables that take this joker value. For this purpose we modify the binary arc constraint in order to discard the vertices for which the corresponding variables are assigned value 0. This will be effectively the case since all the corresponding arcs constraints will not hold.

Algorithm  
An arc-consistency filtering algorithm for the ALLDIFFERENT_EXCEPT_0 constraint is described in [138]. The algorithm is based on the following ideas:

- First, one can map solutions to the ALLDIFFERENT_EXCEPT_0 constraint to var-perfect matchings\(^5\) in a bipartite graph derived from the domain of the variables of the constraint in the following way: to each variable of the ALLDIFFERENT_EXCEPT_0 constraint corresponds a variable and a joker vertices, while to each potential value corresponds a value vertex; there is an edge between a variable vertex and a value vertex if and only if that value belongs to the domain of the corresponding variable; there is an edge between a variable vertex and its corresponding value vertex.

- Second, Dulmage-Mendelsohn decomposition [157] is used to characterise all edges that do not belong to any var-perfect matching, and therefore prune the corresponding variables.

Counting

\(^5\) A var-perfect matching is a maximum matching covering all vertices representing variables.
Systems ALLDIFFERENT in MiniZinc.

See also cost variant: WEIGHTED_PARTIAL_ALLDIFF.
hard version: ALLDIFFERENT.

implied by: ALLDIFFERENT.

implies: MULTI_GLOBAL_CONTIGUITY.

Keywords

characteristic of a constraint: joker value, all different, sort based reformulation, automaton, automaton with array of counters.

constraint type: value constraint, relaxation.

filtering: bipartite matching, arc-consistency.

final graph structure: one_suc.
The graph model is the same as the one used for the `ALLDIFFERENT` constraint, except that we discard all variables that are assigned value 0.

Parts (A) and (B) of Figure 5.42 respectively show the initial and final graph associated with the `Example` slot. Since we use the `MAX_NSCC` graph property we show one of the largest strongly connected components of the final graph. The `ALLDIFFERENT_EXCEPT_0` holds since all the strongly connected components have at most one vertex: a value different from 0 is used at most once.

![Graph Model](image)

Figure 5.42: Initial and final graph of the `ALLDIFFERENT_EXCEPT_0` constraint
ALLDIFFERENT_EXCEPT_0

Automaton Figure 5.43 depicts the automaton associated with the ALLDIFFERENT_EXCEPT_0 constraint. To each variable $\text{VAR}_i$ of the collection $\text{VARIABLES}$ corresponds a 0-1 signature variable $S_i$. The following signature constraint links $\text{VAR}_i$ and $S_i$: $\text{VAR}_i \neq 0 \Leftrightarrow S_i$. The automaton counts the number of occurrences of each value different from 0 and finally imposes that each non-zero value is taken at most one time.

$\text{VAR}_i = 0$

{\{C[.] = 0\} \rightarrow \text{VAR}_i \neq 0, \{C[\text{VAR}_i] = C[\text{VAR}_i] + 1\}}

Figure 5.43: Automaton of the ALLDIFFERENT_EXCEPT_0 constraint
5.19 ALLDIFFERENT_INTERVAL

Origin

Derived from ALLDIFFERENT.

Constraint

ALLDIFFERENT_INTERVAL(VARIABLES, SIZE_INTERVAL)

Synonyms

ALLDIFF_INTERVAL, ALLDISTINCT_INTERVAL.

Arguments

VARIABLES : collection(var−dvar)
SIZE_INTERVAL : int

Restrictions

required(VARIABLES, var)
SIZE_INTERVAL > 0

Purpose

Enforce all variables of the collection VARIABLES to belong to distinct intervals. The intervals are defined by [SIZE_INTERVAL·k, SIZE_INTERVAL·k + SIZE_INTERVAL − 1] where k is an integer.

Example

((2, 4, 10), 3)

In the example, the second argument SIZE_INTERVAL = 3 defines the following family of intervals [3·k, 3·k + 2], where k is an integer. Since the three variables of the collection VARIABLES take values that are respectively located within the three following distinct intervals [0, 2], [3, 5] and [9, 11], the ALLDIFFERENT_INTERVAL constraint holds.

All solutions

Figure 5.44 gives all solutions to the following non ground instance of the ALLDIFFERENT_INTERVAL constraint: \[ V_1 \in [0, 7], V_2 \in [1, 2], V_3 \in [2, 3], V_4 \in [0, 9], \]
ALLDIFFERENT_INTERVAL((V_1, V_2, V_3, V_4), 3).

Figure 5.44: All solutions corresponding to the non ground example of the ALLDIFFERENT_INTERVAL constraint of the All solutions slot

Typical

|VARIABLES| > 1
SIZE_INTERVAL > 1
SIZE_INTERVAL < max(range(VARIABLES.var))
Symmetries

- Items of VARIABLES are permutable.
- A value of VARIABLES.var that belongs to the $k$-th interval, of size SIZE_INTERVAL, can be renamed to any unused value of the same interval.
- Two distinct values of VARIABLES.var that belong to two distinct intervals, of size SIZE_INTERVAL, can be swapped.

Arg. properties

Contractible wrt. VARIABLES.

Solution count for ALLDIFFERENT_INTERVAL: domains 0..n
Solution density for ALLDIFFERENT_INTERVAL.

See also implied by: ALL_MIN_DIST.

specialisation: ALLDIFFERENT (variable/constant replaced by variable).
Keywords

characteristic of a constraint: all different, sort based reformulation, automaton, automaton with array of counters.

constraint type: value constraint.

filtering: arc-consistency.

final graph structure: one_suc.

modelling: interval.
Similar to the ALLDIFFERENT constraint, but we replace the binary equality constraint of the ALLDIFFERENT constraint by the fact that two variables are respectively assigned to two values that belong to the same interval. We generate a clique with a belong to the same interval constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed 1.

Parts (A) and (B) of Figure 5.45 respectively show the initial and final graph associated with the Example slot. Since we use the MAX_NS CC graph property we show one of the largest strongly connected component of the final graph.
Figure 5.46 depicts the automaton associated with the `ALLDIFFERENT_INTERVAL` constraint. To each item of the collection `VARIABLES` corresponds a signature variable $S_i$ that is equal to 1. For each interval $[SIZE_INTERVAL \cdot k, SIZE_INTERVAL \cdot k + SIZE_INTERVAL - 1]$ of values the automaton counts the number of occurrences of its values and finally imposes that the values of an interval are taken at most once.

$$\{ C[.] = 0 \} \xrightarrow{1} \{ C[[VAR \cdot SIZE_INTERVAL]] = C[[VAR \cdot SIZE_INTERVAL]] + 1 \}$$

**ARITH**($C, <, 2$)

Figure 5.46: Automaton of the `ALLDIFFERENT_INTERVAL` constraint
5.20 ALLDIFFERENT_MODULO

Origin
Derived from ALLDIFFERENT.

Constraint
ALLDIFFERENT_MODULO(VARIABLES, M)

Synonyms
ALLDIFF_MODULO, ALLDISTINCT_MODULO.

Arguments
VARIABLES : collection(var−dvar)
M : int

Restrictions
required(VARIABLES, var)
M > 0
M ≥ |VARIABLES|

Purpose
Enforce all variables of the collection VARIABLES to have a distinct rest when divided by M.

Example
((25, 1, 14, 3), 5)

The equivalence classes associated with values 25, 1, 14 and 3 are respectively equal to 25 mod 5 = 0, 1 mod 5 = 1, 14 mod 5 = 4 and 3 mod 5 = 3. Since they are distinct the ALLDIFFERENT_MODULO constraint holds.

All solutions
Figure 5.47 gives all solutions to the following non ground instance of the ALLDIFFERENT_MODULO constraint:

V₁ ∈ {0, 5}, V₂ ∈ [2, 3], V₃ ∈ [3, 4], V₄ ∈ [1, 2],
V₅ ∈ [6, 10], ALLDIFFERENT_MODULO((V₁, V₂, V₃, V₄, V₅), 5).

Figure 5.47: All solutions corresponding to the non ground example of the ALLDIFFERENT_MODULO constraint of the All solutions slot, where the indices (in orange) correspond to the values modulo M = 5: all indices attached to a solution are distinct.

Typical
|VARIABLES| > 2
M > 1
Symmetries

- Items of VARIABLES are permutable.
- A value $u$ of VARIABLES var can be renamed to any value $v$ such that $v$ is congruent to $u$ modulo $M$.
- Two distinct values $u$ and $v$ of VARIABLES var such that $u \mod M \neq v \mod M$ can be swapped.

Arg. properties

Contractible wrt. VARIABLES.

Solution count for \textsc{AllDifferent}\_\textsc{Modulo}: domains $0..n$
See also

**implies:** SOFT_ALLDIFFERENT_VAR.

**specialisation:** ALLDIFFERENT (variable mod constant replaced by variable).
Keywords

- **characteristic of a constraint:** modulo, all different, sort based reformulation, automaton, automaton with array of counters.
- **constraint type:** value constraint.
- **filtering:** arc-consistency.
- **final graph structure:** one_suc.
Graph model

Exploit the same model used for the `ALLDIFFERENT` constraint. We replace the binary `equality` constraint by another equivalence relation depicted by the arc constraint. We generate a `clique` with a binary `equality modulo` $M$ constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed 1.

Parts (A) and (B) of Figure 5.48 respectively show the initial and final graph associated with the Example slot. Since we use the `MAX_NSCC` graph property we show one of the largest strongly connected components of the final graph.

![Figure 5.48: Initial and final graph of the ALLDIFFERENT_MODULO constraint](image-url)
Figure 5.49 depicts the automaton associated with the ALLDIFFERENT_MODULO constraint. To each item of the collection VARIABLES corresponds a signature variable $S_i$ that is equal to 1. The automaton counts for each equivalence class the number of used values and finally imposes that each equivalence class is used at most once.

$$\{C[] = 0\} \xrightarrow{1} \{C[\text{VAR}_i \text{ mod } M] = C[\text{VAR}_i \text{ mod } M] + 1\}$$

Figure 5.49: Automaton of the ALLDIFFERENT_MODULO constraint
| ALLDIFFERENT_MODULO | 603 |
5.21 ALLDIFFERENT_ON_INTERSECTION

Origin
Derived from COMMON and ALLDIFFERENT.

Constraint
ALLDIFFERENT_ON_INTERSECTION(VARIABLES1, VARIABLES2)

Synonyms
ALLDIFF_ON_INTERSECTION, ALLDISTINCT_ON_INTERSECTION.

Arguments
VARIABLES1 : collection(var–dvar)
VARIABLES2 : collection(var–dvar)

Restrictions
required(VARIABLES1, var)
required(VARIABLES2, var)

Purpose
The values that both occur in the VARIABLES1 and VARIABLES2 collections have only one occurrence.

Example
\[(\langle 5, 9, 1, 5 \rangle, \langle 2, 1, 6, 9, 6, 2 \rangle)\]

The ALLDIFFERENT_ON_INTERSECTION constraint holds since the values 9 and 1 that both occur in \(\langle 5, 9, 1, 5 \rangle\) as well as in \(\langle 2, 1, 6, 9, 6, 2 \rangle\) have exactly one occurrence in each collection.

All solutions
Figure 5.50 gives all solutions to the following non ground instance of the ALLDIFFERENT_ON_INTERSECTION constraint: \(U_1 \in [2, 3], U_2 \in [1, 2], V_1 \in [2, 3], V_2 \in [2, 2], V_3 \in [0, 1], ALLDIFFERENT_ON_INTERSECTION(\langle U_1, U_2 \rangle, \langle V_1, V_2, V_3 \rangle)\).

Typical
\[|VARIABLES1| > 1\]
\[|VARIABLES2| > 1\]
Symmetries

- Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Arg. properties

- Contractible wrt. VARIABLES1.
- Contractible wrt. VARIABLES2.

See also

- common keyword: COMMON, NVALUE_ON_INTERSECTION (constraint on the intersection).
- implied by: DISJOINT.
- implies: SAME_INTERSECTION.

Arc constraint(s) | \text{variables1}.\text{var} = \text{variables2}.\text{var}
Graph property(ies) | \text{MAX NCC} \leq 2
Graph class | • ACYCLIC
   • BIPARTITE
   • NO LOOP

Graph model

Parts (A) and (B) of Figure 5.51 respectively show the initial and final graph associated with the **Example** slot. Since we use the **MAX NCC** graph property we show one of the largest connected components of the final graph. The **ALLDIFFERENT ON INTERSECTION** constraint holds since each connected component has at most two vertices. Note that all the vertices corresponding to the variables that take values 5, 2 or 6 were removed from the final graph since there is no arc for which the associated equality constraint holds.

Figure 5.51: Initial and final graph of the **ALLDIFFERENT ON INTERSECTION** constraint
Figure 5.52 depicts the automaton associated with the `ALLDIFFERENT_ON_INTERSECTION` constraint. To each variable $\text{VAR}_1$ of the collection `VARIABLES1` corresponds a signature variable $S_i$ that is equal to 0. To each variable $\text{VAR}_2$ of the collection `VARIABLES2` corresponds a signature variable $S_{i+|\text{VARIABLES1}|}$ that is equal to 1. The automaton first counts the number of occurrences of each value assigned to the variables of the `VARIABLES1` collection. It then counts the number of occurrences of each value assigned to the variables of the `VARIABLES2` collection. Finally, the automaton imposes that each value is not taken by two variables of both collections.

Figure 5.52: Automaton of the `ALLDIFFERENT_ON_INTERSECTION` constraint
5.22 **ALLDIFFERENT_PARTITION**

- **Origin:** Derived from `ALLDIFFERENT`.

- **Constraint:** 
  ```
  ALLDIFFERENT_PARTITION(VARIABLES, PARTITIONS)
  ```

- **Synonyms:** 
  ```
  ALLDIFF_PARTITION, ALLDISTINCT_PARTITION.
  ```

- **Type:**
  ```
  VALUES : collection(val−int)
  ```

- **Arguments:**
  ```
  VARIABLES : collection(var−dvar)
  PARTITIONS : collection(p−VALUES)
  ```

- **Restrictions:**
  ```
  |VALUES| ≥ 1
  required(VARIABLES.val)
  distinct(VARIABLES.val)
  |VARIABLES| ≤ |PARTITIONS|
  required(VARIABLES.var)
  |PARTITIONS| ≥ 2
  required(PARTITIONS.p)
  ```

- **Purpose:** 
  Enforce all variables of the collection `VARIABLES` to take values that belong to distinct partitions.

- **Example:** 
  ```
  ((6,3,4),(p−⟨1,3⟩,p−⟨4⟩,p−⟨2,6⟩))
  ```
  Since all variables take values that are located within distinct partitions the `ALLDIFFERENT_PARTITION` constraint holds.

- **Typical:** 
  ```
  |VARIABLES| > 2
  ```

- **Symmetries:**
  - Items of `VARIABLES` are **permutable**.
  - Items of `PARTITIONS` are **permutable**.
  - Items of `PARTITIONS`.p are **permutable**.
  - A value of `VARIABLES`.var can be renamed to any value that belongs to the same partition of `PARTITIONS`.
  - Two distinct values of `VARIABLES`.var that do not belong to the same partition of `PARTITIONS` can be **swapped**.

- **Arg. properties:** 
  - **Contractible wrt. VARIABLES.**
See also

- **common keyword**: IN\_SAME\_PARTITION \(\text{(partition)}\).
- **specialisation**: ALLDIFFERENT \(\text{(variable} \in \text{partition replaced by variable)}\).
- **used in graph description**: IN\_SAME\_PARTITION.

Keywords

- **characteristic of a constraint**: partition, all different, sort based reformulation.
- **constraint type**: value constraint.
- **filtering**: arc-consistency.
- **final graph structure**: one, succ.
- **modelling**: incompatible pairs of values.
Similar to the ALLDIFFERENT constraint, but we replace the binary equality constraint of the ALLDIFFERENT constraint by the fact that two variables are respectively assigned to two values that belong to the same partition. We generate a clique with an IN_SAME_PARTITION constraint between each pair of vertices (including a vertex and itself) and state that the size of the largest strongly connected component should not exceed 1.

Parts (A) and (B) of Figure 5.53 respectively show the initial and final graph associated with the Example slot. Since we use the MAX_NSCC graph property we show one of the largest strongly connected components of the final graph.

Figure 5.53: Initial and final graph of the ALLDIFFERENT_PARTITION constraint
5.23 ALLDIFFERENTSAMEVALUE

**Origin**  
Derived from ALLDIFFERENT.

**Constraint**  
ALLDIFFERENTSAMEVALUE(NSAME, VARIABLES1, VARIABLES2)

**Synonyms**  
ALLDIFFSAMEVALUE, ALLDISTINCTSAMEVALUE.

**Arguments**  
NSAME : dvar  
VARIABLES1 : collection(var–dvar)  
VARIABLES2 : collection(var–dvar)

**Restrictions**  
NSAME ≥ 0  
NSAME ≤ |VARIABLES1|  
|VARIABLES1| = |VARIABLES2|  
required(VARIABLES1.var)  
required(VARIABLES2.var)

**Purpose**  
All the values assigned to the variables of the collection VARIABLES1 are pairwise distinct. NSAME is equal to number of constraints of the form VARIABLES1[i].var = VARIABLES2[i].var (1 ≤ i ≤ |VARIABLES1|) that hold.

**Example**  
(2, (7, 3, 1, 5), (1, 3, 1, 7))

The ALLDIFFERENTSAMEVALUE constraint holds since:

- All the values 7, 3, 1 and 5 are distinct,
- Among the four expressions 7 = 1, 3 = 3, 1 = 1 and 5 = 7 exactly 2 conditions hold.

**All solutions**  
Figure 5.54 gives all solutions to the following non ground instance of the ALLDIFFERENTSAMEVALUE constraint: U1 ∈ [2, 4], U2 ∈ [1, 2], U3 ∈ [1, 4], U4 ∈ [2, 4], V1 ∈ [2, 3], V2 = 2, V3 ∈ [0, 1], V4 ∈ [0, 3], ALLDIFFERENTSAMEVALUE(3, (U1, U2, U3, U4), (V1, V2, V3, V4)).

**Typical**  
NSAME < |VARIABLES1|  
|VARIABLES1| > 2

**Symmetries**  
- Items of VARIABLES1 and VARIABLES2 are permutable (same permutation used).
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

**Arg. properties**  
Functional dependency: NSAME determined by VARIABLES1 and VARIABLES2.
Figure 5.54: All solutions corresponding to the non ground example of the ALLDIFFERENTSAME_VALUE constraint of the All solutions slot, where identical values at a same position in both collections are coloured in orange.

Usage

When all variables of the second collection are initially bound to distinct values the ALLDIFFERENTSAME_VALUE constraint can be explained in the following way:

- We interpret the variables of the second collection as the previous solution to a problem where all variables have to be distinct.
- We interpret the variables of the first collection as the current solution to find, where all variables should again be pairwise distinct.

The variable NSAME measures the distance of the current solution from the previous solution. This corresponds to the number of variables of VARIABLES2 that are assigned to the same previous value.

See also

root concept: ALLDIFFERENT.

Keywords

characteristic of a constraint: sort based reformulation, automaton, automaton with array of counters.

constraint type: proximity constraint.

modelling: functional dependency.

Cond. implications

\[
\text{ALLDIFFERENTSAME_VALUE}(\text{NSAME}, \text{VARIABLES1}, \text{VARIABLES2})
\]

with \(2 \times \text{NSAME} = |\text{VARIABLES1}| \)

implies \(\text{DIFFERFROMEXACTLYKPOS}(K, \text{VECTOR1}, \text{VECTOR2})\).
**Arc input(s)**

VARIABLES1 VARIABLE2

**Arc generator**

\( \text{PRODUCT}(\text{CLIQUE, LOOP}, =) \mapsto \text{collection}(\text{variables1, variables2}) \)

**Arc arity**

2

**Arc constraint(s)**

\( \text{variables1.var} = \text{variables2.var} \)

**Graph property(ies)**

- \( \text{MAX_NSCC} \leq 1 \)
- \( \text{NARC_NO_LOOP} = \text{NSAME} \)

**Graph model**

The arc generator \( \text{PRODUCT}(\text{CLIQUE, LOOP}, =) \) is used in order to generate all the arcs of the initial graph:

- The arc generator \( \text{CLIQUE} \) creates all links between the items of the first collection VARIABLES1.
- The arc generator \( \text{LOOP} \) creates a loop for each item of the second collection VARIABLES2.
- Finally the arc generator \( \text{PRODUCT}(=) \) creates an arc between items located at the same position in the collections VARIABLES1 and VARIABLES2.

Part (A) of Figure 5.55 gives the initial graph associated with the Example slot. Variables of collection VARIABLES1 are coloured, while variables of collection VARIABLES2 are kept in white. Part (B) represents the final graph associated with the Example slot. In this graph each vertex constitutes a strongly connected component and the number of arcs that do not correspond to a loop is equal to 2 (i.e., NSAME).

![Graph Diagram](image)

**Figure 5.55:** (A) Initial and (B) final graph of the ALLDIFFERENTSAME_VALUE(2, (U_1, U_2, U_3, U_4), (V_1, V_2, V_3, V_4)) constraint with \( U_1 = 7, U_2 = 3, U_3 = 1, U_4 = 5 \) and \( V_1 = 1, V_2 = 3, V_3 = 1, V_4 = 7 \) (in Part (B) arcs in red correspond to the arcs counted by the argument NSAME).
Automaton

Figure 5.56 depicts the automaton associated with the ALLDIFFERENT\_SAME\_VALUE constraint. Let $\text{VAR}_1_i$ and $\text{VAR}_2_i$ respectively denote the $i^{th}$ variables of the VARIABLES\_1 and VARIABLES\_2 collections. To each pair of variables ($\text{VAR}_1_i$, $\text{VAR}_2_i$) corresponds a signature variable $S_i$. The following signature constraint links $\text{VAR}_1_i$, $\text{VAR}_2_i$ and $S_i$: $\text{VAR}_1_i = \text{VAR}_2_i \iff S_i$.

\[
\begin{align*}
\text{VAR}_1_i \neq \text{VAR}_2_i, \\
\{ C[\text{VAR}_1_i] = C[\text{VAR}_1_i] + 1 \}
\end{align*}
\]

\[
\begin{align*}
\{ C[\text{VAR}_1_i] = 0, \\
D = 0 \}
\end{align*}
\]

\[
\begin{align*}
\text{VAR}_1_i = \text{VAR}_2_i, \\
\{ C[\text{VAR}_1_i] = C[\text{VAR}_1_i] + 1, \\
D = D + 1 \}
\end{align*}
\]

\[
\begin{align*}
\text{ARITH}(C, <, 2) \\
\{\text{NSAME} = D \}
\end{align*}
\]

<td>Given a matrix $M$ of domain variables, enforces that the first row is lexicographically less than or equal to all permutations of all other rows. Note that the components of a given vector of the matrix $M$ may be equal.</td>
</tr>
</tbody>
</table>

#### Example

```
((⟨vec − ⟨1, 2, 3⟩, vec − ⟨3, 1, 2⟩⟩)
```

The ALLPERM constraint holds since vector $⟨1, 2, 3⟩$ is lexicographically less than or equal to all the permutations of vector $⟨3, 1, 2⟩$ (i.e., $⟨1, 2, 3⟩$, $⟨1, 3, 2⟩$, $⟨2, 1, 3⟩$, $⟨2, 3, 1⟩$, $⟨3, 1, 2⟩$, $⟨3, 2, 1⟩$).

#### All solutions

Figure 5.57 gives all solutions to the following non ground instance of the ALLPERM constraint: $U_1 \in [1, 2], U_2 \in [1, 2], U_3 \in [1, 3], V_1 \in [0, 1], V_2 \in [1, 2], V_3 \in [0, 2]$, ALLPERM$((⟨U_1, U_2, U_3⟩, ⟨V_1, V_2, V_3⟩))$.

```
① (((1, 1), (1, 1),)) ② (((1, 1), (1, 2),)) ③ (((1, 1), (1, 2),)) ④ (((1, 1), (1, 2),)) ⑤ (((1, 1), (1, 2),))
```

Figure 5.57: All solutions corresponding to the non ground example of the ALLPERM constraint of the All solutions slot
Typical

|VECTOR| > 1  
|MATRIX| > 1  

Symmetry
One and the same constant can be added to the var attribute of all items of MATRIX.vec.

Arg. properties
Suffix-contractible wrt. MATRIX.vec (remove items from same position).

Usage
A symmetry-breaking constraint.

See also
common keyword: LEX2, LEX_CHAIN_LESEQ (matrix symmetry, lexicographic order), LEX_LESEQ (lexicographic order), LEX_LESEQ_ALLPERM (matrix symmetry, lexicographic order), STRICT_LEX2 (lexicographic order).

- \text{matrix2.key} > 1
- \text{LEX_LESSEQ_ALLPERM}(\text{matrix1}.\text{vec}, \text{matrix2}.\text{vec})

### Graph property(ies)
**\text{NARC} = |\text{MATRIX}| - 1**

### Graph class
- ACYCLIC
- BIPARTITE
- NO_LOOP

### Graph model
We generate a graph with an arc constraint \text{LEX_LESSEQ_ALLPERM} between the vertex corresponding to the first item of the MATRIX collection and the vertices associated with all other items of the MATRIX collection. This is achieved by specifying that (1) an arc should start from the first item (i.e., matrix1.key = 1) and (2) an arc should not end on the first item (i.e., matrix2.key > 1). We finally state that all these arcs should belong to the final graph. Parts (A) and (B) of Figure 5.58 respectively show the initial and final graph associated with the **Example** slot.

![Graph Model](image)

**Figure 5.58**: Initial and final graph of the **ALLPERM** constraint
5.25 AMONG

Origin [47]

Constraint AMONG(NVAR, VARIABLES, VALUES)

Synonyms BETWEEN, COUNT.

Arguments
- NVAR : dvar
- VARIABLES : collection(var−dvar)
- VALUES : collection(val−int)

Restrictions
- NVAR ≥ 0
- NVAR ≤ |VARIABLES|
- required(VARIABLES, var)
- required(VARIABLES, val)
- distinct(VARIABLES, val)

Purpose NVAR is the number of variables of the collection VARIABLES that take their values in VALUES.

Example (3, ⟨4, 5, 5, 4, 1⟩, {5, 1})

The AMONG constraint holds since exactly 3 values of the collection of variables ⟨4, 5, 5, 4, 1⟩ belong to the set of values {1, 5, 8}.

All solutions Figure 5.59 gives all solutions to the following non ground instance of the AMONG constraint: \( V_1 \in [1, 5], V_2 \in [3, 9], V_3 \in [5, 6], V_4 \in [2, 3], \) AMONG(3, \( \langle V_1, V_2, V_3, V_4 \rangle, (2, 4) \)).

Figure 5.59: All solutions corresponding to the non ground example of the AMONG constraint of the All solutions slot, where the number of variables assigned a value from \( \{2, 4\} \) is equal to NVAR = 3.
**Typical**

\[
\begin{align*}
\text{NVAR} &> 0 \\
\text{NVAR} &< |\text{VARIABLES}| \\
|\text{VARIABLES}| &> 1 \\
|\text{VALUES}| &> 1 \\
|\text{VARIABLES}| &> |\text{VALUES}|
\end{align*}
\]

**Symmetries**

- Items of \(\text{VARIABLES}\) are permutable.
- Items of \(\text{VALUES}\) are permutable.
- An occurrence of a value of \(\text{VARIABLES}\) \(\text{var}\) that belongs to \(\text{VALUES}\) \(\text{val}\) (resp. does not belong to \(\text{VALUES}\) \(\text{val}\)) can be replaced by any other value in \(\text{VALUES}\) \(\text{val}\) (resp. not in \(\text{VALUES}\) \(\text{val}\)).

**Arg. properties**

- **Functional dependency**: \(\text{NVAR}\) determined by \(\text{VARIABLES}\) and \(\text{VALUES}\).
- **Contractible** wrt. \(\text{VARIABLES}\) when \(\text{NVAR} = 0\).
- **Contractible** wrt. \(\text{VARIABLES}\) when \(\text{NVAR} = |\text{VARIABLES}|\).
- **Aggregate**: \(\text{NVAR}(+), \text{VARIABLES}(\text{union}), \text{VALUES}(\text{sunion})\).

**Remark**

A similar constraint called **BETWEEN** was introduced in **CHIP** in 1990.

The **COMMON** constraint can be seen as a generalisation of the **AMONG** constraint where we allow the \(\text{val}\) attributes of the \(\text{VALUES}\) collection to be domain variables.

A generalisation of this constraint when the values of \(\text{VALUES}\) are not initially fixed is called **AMONG\_VAR**.

When the variable \(\text{NVAR}\) (i.e., the first argument of the **AMONG** constraint) does not occur in any other constraints of the problem, it may be operationally more efficient to replace the **AMONG** constraint by an **AMONG\_LOW\_UP** constraint where \(\text{NVAR}\) is replaced by the corresponding interval \([\text{NVAR}, \text{NVAR}]\). This stands for two reasons:

- First, by using an **AMONG\_LOW\_UP** constraint rather than an **AMONG** constraint, we avoid the filtering algorithm related to \(\text{NVAR}\).
- Second, unlike the **AMONG** constraint where we need to fix all its variables to get entailment, the **AMONG\_LOW\_UP** constraint can be entailed before all its variables get fixed. As a result, this potentially avoid unnecessary calls to its filtering algorithm.

It was shown in [116] that achieving bound-consistency for a conjunction of **AMONG** constraints where all sets of values are arbitrary intervals can be done in polynomial time.

**Algorithm**

A filtering algorithm achieving arc-consistency was given by Bessière et al. in [67, 70].

**Systems**

**AMONG** in **Choco**, **COUNT** in **Gecode**, **AMONG** in **JaCoP**, **AMONG** in **MiniZinc**.

- generalisation: **AMONG\_VAR** (constant replaced by variable).
- implies: **AMONG\_VAR**, **CARDINALITY\_ATMOST**.
related: ROOTS (can be used for expressing AMONG), SLIDING_CARD_SKIP0 (counting constraint on maximal sequences).

shift of concept: AMONG_SEQ (variable replaced by interval and constraint applied in a sliding way), COMMON.

soft variant: OPEN_AMONG (open constraint).

specialisation: AMONG_DIFF_0 (variable ∈ values replaced by variable different from 0), AMONG_INTERVAL (variable ∈ values replaced by variable ∈ interval), AMONG_LOW_UP (variable replaced by interval), AMONG_MODULO (list of values replaced by list of values v such that v mod QUOTIENT = REMAINDER), EXACTLY (variable replaced by constant and values replaced by one single value).

system of constraints: GLOBAL_CARDINALITY (count the number of occurrences of different values).

used in graph description: IN.

uses in its reformulation: COUNT.

Keywords

characteristic of a constraint: automaton, automaton with counters, non-deterministic automaton.

constraint arguments: reverse of a constraint, pure functional dependency.

constraint network structure: alpha-acyclic constraint network(2), Berge-acyclic constraint network.

constraint type: value constraint, counting constraint.

filtering: glue matrix, arc-consistency, SAT.

modelling: functional dependency.
The arc constraint corresponds to the unary constraint \( \text{IN}(\text{variables}.\text{var}, \text{VALUES}) \) defined in this catalogue. Since this is a unary constraint we employ the \textit{SELF} arc generator in order to produce an initial graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.60 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the \textbf{NARC} graph property, the loops of the final graph are stressed in bold.

![Graph model](image)

**Figure 5.60:** Initial and final graph of the \textsc{among} constraint
Automaton

Figure 5.61 depicts a first automaton that only accepts all the solutions to the AMONG constraint. This automaton uses a counter in order to record the number of satisfied constraints of the form \( \text{VAR}_i \in \text{VALUES} \) already encountered. To each variable \( \text{VAR}_i \) of the collection \( \text{VARIABLES} \) corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i \in \text{VALUES} \iff S_i \). The automaton counts the number of variables of the \( \text{VARIABLES} \) collection that take their values in \( \text{VALUES} \) and finally assigns this number to \( \text{NVAR} \).

\[
\begin{align*}
\text{NOT_IN}(\text{VAR}_i, \text{VALUES}) \\
\{C \leftarrow 0\} & \xrightarrow{s} \text{IN}(\text{VAR}_i, \text{VALUES}), \{C \leftarrow C + 1\} \\
\text{NVAR} = C
\end{align*}
\]

Figure 5.61: Automaton (with one counter) of the AMONG constraint and its glue matrix

We now describe a second counter free automaton that also only accepts all the solutions to AMONG constraint. Without loss of generality, assume that the collection of variables \( \text{VARIABLES} \) contains at least one variable (i.e., \( |\text{VARIABLES}| \geq 1 \)). Let \( n \) and \( D \) respectively denote the number of variables of the collection \( \text{VARIABLES} \), and the union of the domains of the variables of \( \text{VARIABLES} \). Clearly, the maximum number of variables of \( \text{VARIABLES} \) that are assigned a value in \( \text{VALUES} \) cannot exceed the quantity \( m = \min(n, \text{NVAR}) \). The \( m + 2 \) states of the automaton that only accepts all the solutions to the AMONG constraint can be defined in the following way:

- We have an initial state labelled by \( s_0 \).
- We have \( m \) intermediate states labelled by \( s_i \) (\( 1 \leq i \leq m \)). The intermediate states are indexed by the number of already encountered satisfied constraints of the form \( \text{VAR}_i \in \text{VALUES} \) from the initial state \( s_0 \) to the state \( s_i \).
We have an accepting state labelled by $s_F$.

Three classes of transitions are respectively defined in the following way:

1. There is a transition, labeled by $j$, $(j \in \mathcal{D} \setminus \text{VALUES})$, from every state $s_i$, $(i \in [0, m])$, to itself.
2. There is a transition, labeled by $j$, $(j \in \text{VALUES})$, from every state $s_i$, $(i \in [0, m - 1])$, to the state $s_{i+1}$.
3. There is a transition, labelled by $i$, from every state $s_i$, $(i \in [0, m])$, to the accepting state $s_F$.

This leads to an automaton that has $m \cdot |\mathcal{D}| + |\mathcal{D} \setminus \text{VALUES}| + m + 1$ transitions. Since the maximum value of $m$ is equal to $n$, in the worst case we have $n \cdot |\mathcal{D}| + |\mathcal{D} \setminus \text{VALUES}| + n + 1$ transitions.

Figure 5.63 depicts a counter free non deterministic automaton associated with the AMONG constraint under the hypothesis that (1) all variables of VARIABLES are assigned a value in \{0, 1, 2, 3\}, (2) $|\text{VALUES}|$ is equal to 3, (3) VALUES corresponds to odd values. The sequence $\text{VAR}_1, \text{VAR}_2, \ldots, \text{VAR}_{|\text{VARIABLES}|}, \text{NVAR}$ is passed to this automaton. A state $s_i$ $(1 \leq i \leq 3)$ represents the fact that $i$ odd values were already encountered, while $s_F$ represents the accepting state. A transition from $s_i$ $(1 \leq i \leq 3)$ to $s_F$ is labelled by $i$ and represents the fact that we can only go in the accepting state from a state that is compatible with the total number of odd values enforced by NVAR. Note that non determinism only occurs if there is a non-empty intersection between the set of potential values that can be assigned to the variables of VARIABLES and the potential value of the NVAR. While the counter free non deterministic automaton depicted by Figure 5.63 has 5 states and 18 transitions, its minimum-state deterministic counterpart shown in Figure 5.64 has 7 states and 23 transitions.

We make the following final observation. Since the Symmetries slot of the AMONG constraint indicates that the variables of VARIABLES are permutable, and since all incoming transitions to any state of the automaton depicted by Figure 5.63 are labelled with distinct values, we can mechanically construct from this automaton a counter free deterministic automaton that takes as input the sequence NVAR, $\langle \text{VAR}_1, \text{VAR}_2, \text{VAR}_3 \rangle$, $\langle 1, 3 \rangle$ constraint assuming $\text{VAR}_i \in [0, 3]$ $(1 \leq i \leq 3)$, with initial state $s_0$ and accepting state $s_F$.
The sequence of variables \( \text{VAR}_1, \text{VAR}_2, \text{VAR}_3, \text{NVAR} \) is passed to the automaton.

Figure 5.64: Counter free minimum-state deterministic automaton of the \( \text{AMONG(\text{NVAR}, \langle \text{VAR}_1, \text{VAR}_2, \text{VAR}_3 \rangle, \langle 1, 3 \rangle) \) constraint assuming \( \text{VAR}_i \in [0, 3] \) \( 1 \leq i \leq 3 \), with initial state \( s_0 \) and accepting states \( s_1, s_3, s_6 \)
AMONG 627
5.26 AMONG_DIFF_0

Origin
Used in the automaton of NVALUE.

Constraint
AMONG_DIFF_0(NVAR, VARIABLES)

Arguments
NVAR : dvar
VARIABLES : collection(var−dvar)

Restrictions
NVAR ≥ 0
NVAR ≤ |VARIABLES|
required(VARIABLES, var)

Purpose
NVAR is the number of variables of the collection VARIABLES that take a value different from 0.

Example
(3, (0, 5, 5, 0, 1))
(0, (0, 0, 0, 0, 0))
(1, (0, 0, 0, 6, 0))

The first AMONG_DIFF_0 constraint holds since exactly 3 values of the collection of values (0, 5, 5, 0, 1) are different from 0.

All solutions
Figure 5.65 gives all solutions to the following non ground instance of the AMONG_DIFF_0 constraint: \(V_1 \in \{0, 3\}, V_2 \in \{0, 1\}, V_3 \in \{5, 6\}, V_4 \in \{0, 2\}\), AMONG_DIFF_0(2, (V1, V2, V3, V4)).

Figure 5.65: All solutions corresponding to the non ground example of the AMONG_DIFF_0 constraint of the All solutions slot, where the number of variables assigned a value different from zero is equal to \(NVAR = 2\)

Typical
NVAR > 0
NVAR < |VARIABLES|
|VARIABLES| > 1
ATLEAST(1, VARIABLES, 0)
2 * AMONG_DIFF_0(VARIABLES.var) > |VARIABLES|
**Typical model**

\[ \text{ATLEAST}(2, \text{VARIABLES}, 0) \]

**Symmetries**

- Items of \text{VARIABLES} are \textit{permutable}.
- An occurrence of a value of \text{VARIABLES}.\text{var} that is different from 0 can be \textit{replaced} by any other value that is also different from 0.

**Arg. properties**

- \textit{Functional dependency}: \text{NVAR} determined by \text{VARIABLES}.
- \textit{Contractible} wrt. \text{VARIABLES} when \text{NVAR} = 0.
- \textit{Contractible} wrt. \text{VARIABLES} when \text{NVAR} = \lvert \text{VARIABLES} \rvert.
- \textit{Aggregate}: \text{NVAR}(+), \text{VARIABLES}(\text{union}).

**Counting**

**Graph model**

Since this is a unary constraint we employ the $SELF$ arc generator in order to produce an initial graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.66 respectively show the initial and final graph associated with the first example of the Example slot. Since we use the $\text{NARC}$ graph property, the loops of the final graph are stressed in bold.

![Graph](image)

**Figure 5.66:** Initial and final graph of the AMONG_DIFF_0 constraint
Automaton

Figure 5.67 depicts the automaton associated with the AMONG_DIFF_0 constraint. To each variable $\text{VAR}_i$ of the collection $\text{VARIABLES}$ corresponds a 0-1 signature variable $S_i$. The following signature constraint links $\text{VAR}_i$ and $S_i$: $\text{VAR}_i \neq 0 \iff S_i$. The automaton counts the number of variables of the $\text{VARIABLES}$ collection that take a value different from 0 and finally assigns this number to $\text{NVAR}$.

![Automaton Diagram]

Figure 5.67: Automaton of the AMONG_DIFF_0 constraint

Figure 5.68: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the AMONG_DIFF_0 constraint: since all states variables $Q_0, Q_1, \ldots, Q_n$ are fixed to the unique state $s$ of the automaton, the transitions constraints share only the counter variable $C$ and the constraint network is Berge-acyclic.
5.27 AMONG_INTERVAL

Description

Origin
- Derived from AMONG.

Constraint
- AMONG_INTERVAL(NVAR, VARIABLES, LOW, UP)

Arguments
- NVAR : dvar
- VARIABLES : collection(var - dvar)
- LOW : int
- UP : int

Restrictions
- NVAR ≥ 0
- NVAR ≤ |VARIABLES|
- required(VARIABLES, var)
- LOW ≤ UP

Purpose
- NVAR is the number of variables of the collection VARIABLES taking a value that is located within interval [LOW, UP].

Example
- (3, ⟨4, 5, 8, 4, 1⟩, 3, 5)

The AMONG_INTERVAL constraint holds since we have 3 values, namely 4, 5 and 4 that are situated within interval [3, 5].

All solutions
- Figure 5.69 gives all solutions to the following non ground instance of the AMONG_INTERVAL constraint: V_1 ∈ [2, 9], V_2 ∈ [0, 1], V_3 ∈ [5, 6], V_4 ∈ [1, 2], AMONG_INTERVAL(3, ⟨V_1, V_2, V_3, V_4⟩, 0, 2).

Figure 5.69: All solutions corresponding to the non ground example of the AMONG_INTERVAL constraint of the All solutions slot, where the number of variables assigned a value in [LOW = 0, UP = 2] is equal to NVAR = 3.
AMONG_INTERVAL

Typical

- NVAR > 0
- NVAR < |VARIABLES|
- |VARIABLES| > 1
- LOW < UP
- LOW ≤ maxval(VARIABLES.var)
- UP ≥ minval(VARIABLES.var)

Symmetries

- Items of VARIABLES are permutable.
- An occurrence of a value of VARIABLES.var that belongs to [LOW, UP] (resp. does not belong to [LOW, UP]) can be replaced by any other value in [LOW, UP] (resp. not in [LOW, UP]).

Arg. properties

- Functional dependency: NVAR determined by VARIABLES, LOW and UP.
- Contractible wrt. VARIABLES when NVAR = 0.
- Contractible wrt. VARIABLES when NVAR = |VARIABLES|.
- Aggregate: NVAR(+), VARIABLES(union), LOW(id), UP(id).

Remark

By giving explicitly all values of the interval [LOW, UP] the AMONG_INTERVAL constraint can be modelled with the AMONG constraint. However when LOW – UP + 1 is a large quantity the AMONG_INTERVAL constraint provides a more compact form.

See also

generalisation: AMONG (variable in interval replaced by variable ∈ values).

Keywords

characteristic of a constraint: automaton, automaton with counters.
constraint arguments: pure functional dependency.
constraint network structure: alpha-acyclic constraint network(2).
constraint type: value constraint, counting constraint.
filtering: arc-consistency.
modelling: interval, functional dependency.
The arc constraint corresponds to a unary constraint. For this reason we employ the \textit{SELF} arc generator in order to produce a graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.70 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the \textit{NARC} graph property, the loops of the final graph are stressed in bold.

\end{tikzpicture}
\end{minipage}
\caption{Initial and final graph of the AMONG INTERVAL constraint}
\end{figure}
Automaton

Figure 5.71 depicts the automaton associated with the AMONG_INTERVAL constraint. To each variable $\text{VAR}_i$ of the collection VARIABLES corresponds a 0-1 signature variable $S_i$. The following signature constraint links $\text{VAR}_i$ and $S_i$: $\text{LOW} \leq \text{VAR}_i \land \text{VAR}_i \leq \text{UP} \Leftrightarrow S_i$. The automaton counts the number of variables of the VARIABLES collection that take their values in $[\text{LOW}, \text{UP}]$ and finally assigns this number to $\text{NVAR}$.

$$\text{LOW} > \text{VAR}_i \lor \text{VAR}_i > \text{UP}$$

$$\{C \leftarrow 0\} \quad \text{LOW} \leq \text{VAR}_i \land \text{VAR}_i \leq \text{UP}, \quad \{C \leftarrow C + 1\}$$

$$\text{NVAR} = C$$

Figure 5.71: Automaton of the AMONG_INTERVAL constraint

Figure 5.72: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the AMONG_INTERVAL constraint: since all states variables $Q_0, Q_1, \ldots, Q_n$ are fixed to the unique state $s$ of the automaton, the transitions constraints share only the counter variable $C$ and the constraint network is Berge-acyclic
5.28 AMONG_LOW_UP

**Origin**

[47]

**Constraint**

AMONG_LOW_UP(LOW, UP, VARIABLES, VALUES)

**Arguments**

- LOW : int
- UP : int
- VARIABLES : collection(var–dvar)
- VALUES : collection(val–int)

**Restrictions**

- LOW ≥ 0
- LOW ≤ |VARIABLES|
- UP ≥ 0
- UP ≤ |VARIABLES|
- UP ≥ LOW
  - required(VARIABLES, var)
  - required VALUES, val)
  - distinct VALUES, val)

**Purpose**

Between LOW and UP variables of the VARIABLES collection are assigned a value of the VALUES collection.

**Example**

(1, 2, ⟨9, 2, 4, 5⟩, ⟨0, 2, 4, 6, 8⟩)

The AMONG_LOW_UP constraint holds since between 1 and 2 values (i.e., in fact 2 values) of the collection of values ⟨9, 2, 4, 5⟩ belong to the set of values {0, 2, 4, 6, 8}.

**All solutions**

Figure 5.73 gives all solutions to the following non ground instance of the AMONG_LOW_UP constraint: \( V_1 \in [1, 2], V_2 \in [8, 9], V_3 \in [5, 6], V_4 \in [2, 3], \)

AMONG_LOW_UP(3, 4, ⟨V_1, V_2, V_3, V_4⟩, ⟨0, 2, 4, 6, 8⟩).

**Typical**

- LOW < |VARIABLES|
- UP > 0
- LOW < UP
- |VARIABLES| > 1
- |VALUES| > 1
- |VARIABLES| > |VALUES|
- LOW > 0 ∨ UP < |VARIABLES|
AMONG_LOW_UP

Figure 5.73: All solutions corresponding to the non ground example of the AMONG_LOW_UP constraint of the All solutions slot, where at least three variables (LOW = 3, UP = 4) are assigned a value from \{0, 2, 4, 6, 8\}

Symmetries

- Items of VARIABLES are permutable.
- Items of VALUES are permutable.
- LOW can be decreased to any value \(\geq 0\).
- UP can be increased to any value \(\leq |\text{VARIABLES}|\).
- An occurrence of a value of VARIABLES.val that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

Arg. properties

- Contractible wrt. VARIABLES when UP = 0.
- Contractible wrt. VARIABLES when UP = |VARIABLES|.
- Aggregate: LOW(+), UP(+), VARIABLES(union), VALUES(sunion).

Algorithm

The AMONG_LOW_UP constraint is entailed if and only if the following two conditions hold:

1. The number of variables of the VARIABLES collection assigned a value of the VALUES collection is greater than or equal to LOW.
2. The number of variables of the VARIABLES collection that can potentially be assigned a value of the VALUES collection is less than or equal to UP.

Used in

AMONG_SEQ, CYCLE_CARD_ON_PATH, INTERVAL_AND_COUNT, SLIDING_CARD_SKIP0.

See also

assignment dimension added: INTERVAL_AND_COUNT (assignment dimension corresponding to intervals added).

generalisation: AMONG (interval replaced by variable), SLIDING_CARD_SKIP0 (full sequence replaced by maximal sequences of non-zeros).

system of constraints: AMONG_SEQ.

Keywords

characteristic of a constraint: automaton, automaton with counters.

constraint network structure: alpha-acyclic constraint network(2).

constraint type: value constraint, counting constraint.

filtering: arc-consistency, entailment.

final graph structure: acyclic, bipartite, no loop.
Cond. implications

\[ \text{AMONG}_\text{LOW}_\text{UP}(\text{LOW, UP, VARIABLES, VALUES}) \]

\[ \text{with distinct(VARIABLES, var)} \]

\[ \text{implies } \text{AMONG}_\text{LOW}_\text{UP}(\text{LOW, UP, VALUES, VARIABLES}). \]

**Graph model**

Each arc constraint of the final graph corresponds to the fact that a variable is assigned to a value that belong to the VALUES collection. The two graph properties restrict the total number of arcs to the interval $[\text{LOW}, \text{UP}]$.

Parts (A) and (B) of Figure 5.74 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

**Figure 5.74:** Initial and final graph of the AMONG_LOW_UP constraint
Figure 5.75 depicts the automaton associated with the AMONG_LOW_UP constraint. To each variable \( \text{VAR}_i \) of the collection \( \text{VARIABLES} \) corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i \in \text{VALUES} \Leftrightarrow S_i \). The automaton counts the number of variables of the \( \text{VARIABLES} \) collection that take their values in \( \text{VALUES} \) and finally checks that this number is within the interval \([\text{LOW}, \text{UP}]\).

\[
\text{LOW} \leq C \land C \leq \text{UP}
\]

Figure 5.75: Automaton of the AMONG_LOW_UP constraint

Figure 5.76: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the AMONG_LOW_UP constraint: since all states variables \( Q_0, Q_1, \ldots, Q_n \) are fixed to the unique state \( s \) of the automaton, the transitions constraints share only the counter variable \( C \) and the constraint network is Berge-acyclic.
5.29 AMONG_MODULO

Origin
Derived from AMONG.

Constraint
AMONG_MODULO(NVAR, VARIABLES, REMAINDER, QUOTIENT)

Arguments
NVAR : dvar
VARIABLES : collection(var−dvar)
REMAINDER : int
QUOTIENT : int

Restrictions
NVAR ≥ 0
NVAR ≤ |VARIABLES|
required(VARIABLES, var)
REMAINDER ≥ 0
REMAINDER < QUOTIENT
QUOTIENT > 0

Purpose
NVAR is the number of variables of the collection VARIABLES taking a value that is congruent to REMAINDER modulo QUOTIENT.

Example
(3, ⟨4, 5, 8, 4, 1⟩, 0, 2)

In this example REMAINDER = 0 and QUOTIENT = 2 specifies that we count the number of even values taken by the different variables. As a consequence the AMONG_MODULO constraint holds since exactly 3 values of the collection ⟨4, 5, 8, 4, 1⟩ are even.

All solutions
Figure 5.77 gives all solutions to the following non ground instance of the AMONG_MODULO constraint: NVAR ∈ [3, 4], V_1 ∈ [1, 2], V_2 ∈ [8, 9], V_3 ∈ [5, 6], V_4 ∈ [2, 3], AMONG_MODULO(NVAR, ⟨V_1, V_2, V_3, V_4⟩, 1, 2).

Figure 5.77: All solutions corresponding to the non ground example of the AMONG_MODULO constraint of the All solutions slot, where the number of variables assigned an odd value (REMAINDER = 1, QUOTIENT = 2) is constrained to be equal to NVAR ∈ [3, 4]
Among Modulo

**Typical**
- `NVAR > 0`
- `NVAR < |VARIABLES|`
- `|VARIABLES| > 1`
- `QUOTIENT > 1`
- `QUOTIENT < maxval(VARIABLES.var)`

**Symmetries**
- Items of `VARIABLES` are permutable.
- An occurrence of a value `u` of `VARIABLES.var` such that `u mod QUOTIENT = REMAINDER` (resp. `u mod QUOTIENT ≠ REMAINDER`) can be replaced by any other value `v` such that `v mod QUOTIENT = REMAINDER` (resp. `v mod QUOTIENT ≠ REMAINDER`).

**Arg. properties**
- **Functional dependency**: `NVAR` determined by `VARIABLES`, `REMAINDER` and `QUOTIENT`.
- **Contractible wrt. `VARIABLES`** when `NVAR = 0`.
- **Contractible wrt. `VARIABLES`** when `NVAR = |VARIABLES|`.
- **Aggregate**: `NVAR(+), VARIABLES(union), REMAINDER(id), QUOTIENT(id)`.

**Remark**
By giving explicitly all values `v` that satisfy the equality `v mod QUOTIENT = REMAINDER`, the `AMONG_MODULO` constraint can be modelled with the `AMONG` constraint. However the `AMONG_MODULO` constraint provides a more compact form.

**See also**
- **generalisation**: `AMONG(list of values v such that v mod QUOTIENT = REMAINDER replaced by list of values)`.

**Keywords**
- **characteristic of a constraint**: modulo, automaton, automaton with counters.
- **constraint arguments**: pure functional dependency.
- **constraint network structure**: alpha-acyclic constraint network(2).
- **constraint type**: value constraint, counting constraint.
- **filtering**: arc-consistency.
- **modelling**: functional dependency.
The arc constraint corresponds to a unary constraint. For this reason we employ the \emph{SELF} arc generator in order to produce a graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.78 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the \textbf{NARC} graph property, the loops of the final graph are stressed in bold.

Figure 5.78: Initial and final graph of the AMONG\_MODULO constraint
Automaton

Figure 5.79 depicts the automaton associated with the AMONG_MODULO constraint. To each variable \( \text{VAR}_i \) of the collection VARIABLES corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i \mod \text{QUOTIENT} = \text{REMAINDER} \Leftrightarrow S_i \).

\[
\begin{align*}
\text{VAR}_i \mod \text{QUOTIENT} &\neq \text{REMAINDER} \\
\{ C \leftarrow 0 \} &\quad s & \quad \text{VAR}_i \mod \text{QUOTIENT} = \text{REMAINDER}, \\
\{ C \leftarrow C + 1 \} &
\end{align*}
\]

Figure 5.79: Automaton of the AMONG_MODULO constraint

Figure 5.80: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the AMONG_MODULO constraint: since all states variables \( Q_0, Q_1, \ldots, Q_n \) are fixed to the unique state \( s \) of the automaton, the transitions constraints share only the counter variable \( C \) and the constraint network is Berge-acyclic.

</table>
Figure 5.81: All solutions corresponding to the non ground example of the AMONG_SEQ constraint of the All solutions slot, where each sequence of two consecutive variables (SEQ = 2) does not contain more than one occurrence (LOW = 0, UP = 1) of values 0, 2, 4, 6, 8

Symmetries
- Items of VARIABLES can be reversed.
- Items of VALUES are permutable.
- LOW can be decreased to any value ≥ 0.
- UP can be increased to any value ≤ SEQ.
- An occurrence of a value of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

Arg. properties
- Contractible wrt. VARIABLES when UP = 0.
- Contractible wrt. VARIABLES when SEQ = 1.
- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

Usage
The AMONG_SEQ constraint occurs in many timetabling problems. As a typical example taken from [437], consider, for example, a nurse-rostering problem where each nurse can work at most 2 night shifts during every period of 7 consecutive days.

Algorithm
Beldiceanu and Carlsson [32] have proposed a first incomplete filtering algorithm for the AMONG_SEQ constraint. Later on, W.-J. van Hoeve et al. proposed two filtering algorithms [437] establishing arc-consistency as well as an incomplete filtering algorithm based on dynamic programming concepts. In 2007 Brand et al. came up with a reformulation [96] that provides a complete filtering algorithm. One year later, Maher et al. use a reformulation in terms of a linear program [284] where (1) each coefficient is an integer in \{-1, 0, 1\}, (2) each column has a block of consecutive 1’s or -1’s. From this reformulation they derive a flow model that leads to an algorithm that achieves a complete filtering in \(O(n^2)\) along a branch of the search tree.

<td>$\text{AMONG}_{\text{LOW, UP}}(\text{LOW, UP, collection, VALUES})$</td>
</tr>
<tr>
<td>Graph property(ies)</td>
<td>$\text{NARC} =</td>
</tr>
</tbody>
</table>

**Graph model**

A constraint on sliding sequences of consecutive variables. Each vertex of the graph corresponds to a variable. Since they link SEQ variables, the arcs of the graph correspond to hyperarcs. In order to link SEQ consecutive variables we use the arc generator $PATH$. The constraint associated with an arc corresponds to the $\text{AMONG}_{\text{LOW, UP}}$ constraint defined at another entry of this catalogue.

**Signature**

Since we use the $PATH$ arc generator with an arity of SEQ on the items of the VARIABLES collection, the expression $|\text{VARIABLES}| - \text{SEQ} + 1$ corresponds to the maximum number of arcs of the final graph. Therefore we can rewrite the graph property $\text{NARC} = |\text{VARIABLES}| - \text{SEQ} + 1$ to $\text{NARC} \geq |\text{VARIABLES}| - \text{SEQ} + 1$ and simplify $\text{NARC}$ to $\text{NARC}$. 
### 5.31 AMONG_VAR

**Origin**
Generalisation of AMONG

**Constraint**
AMONG_VAR(NVAR, VARIABLES, VALUES)

**Arguments**
- NVAR : dvar
- VARIABLES : collection(var−dvar)
- VALUES : collection(val−dvar)

**Restrictions**
- \( NVAR \geq 0 \)
- \( NVAR \leq |VARIABLES| \)
- required(VARIABLES, var)
- required(VALUES, val)

**Purpose**
\( NVAR \) is the number of variables of the collection VARIABLES that are equal to one of the variables of the collection VALUES.

**Example**
\( (3, \langle 4, 5, 5, 4, 1 \rangle, \langle 1, 5, 8, 1 \rangle) \)

The AMONG_VAR constraint holds since exactly 3 values of the collection of variables \( \langle 4, 5, 5, 4, 1 \rangle \) occurs within the collection \( \langle 1, 5, 8, 1 \rangle \).

**All solutions**
Figure 5.82 gives all solutions to the following non ground instance of the AMONG_VAR constraint: \( NVAR \in [3, 4], V_1 \in [1, 2], V_2 \in [8, 9], V_3 \in [5, 6], V_4 \in [2, 3], AMONG_VAR(NVAR, \langle V_1, V_2, V_3, V_4 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \).

1. \( (3, \langle 1, 8, 6, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \)
2. \( (3, \langle 2, 8, 5, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \)
3. \( (4, \langle 2, 8, 6, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \)
4. \( (3, \langle 2, 8, 6, 3 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \)
5. \( (3, \langle 2, 9, 6, 2 \rangle, \langle 0, 2, 4, 6, 8 \rangle) \)

Figure 5.82: All solutions corresponding to the non ground example of the AMONG_VAR constraint of the All solutions slot, where the number of variables assigned a value in \( \{0, 2, 4, 6, 8\} \) is equal to \( NVAR \in [3, 4] \)

**Typical**
- \( |VARIABLES| > 1 \)
- \( |VALUES| > 1 \)
- \( |VARIABLES| > |VALUES| \)
AMONG_VAR

Symmetries

- Items of VARIABLES are permutable.
- Items of VALUES are permutable.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.
- An occurrence of a value of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

Arg. properties

- Functional dependency: NVAR determined by VARIABLES and VALUES.
- Contractible wrt. VARIABLES when NVAR = 0.
- Contractible wrt. VARIABLES when NVAR = |VARIABLES|.
- Aggregate: NVAR(+), VARIABLES(union), VALUES(union).

Systems

AMONG in Choco, COUNT in Gecode, AMONGVAR in JaCoP.

### 5.33 ARITH

**Origin**  
Used in the definition of several automata

**Constraint**  
\( \text{ARITH} (\text{VARIABLES}, \text{RELOP}, \text{VALUE}) \)

**Synonym**  
REL

**Arguments**  
- VARIABLES : collection\((\text{var} - \text{dvar})\)
- RELOP : atom
- VALUE : int

**Restrictions**  
- required(VARIABLES, var)
- RELOP \( \in \{=, \neq, <, \geq, >, \leq\} \)

**Purpose**  
Enforce for all variables var of the VARIABLES collection to have \( \text{var} \text{ RELOP} \text{ VALUE} \).

**Example**  
\( ((4,5,7,4,5), <, 9) \)

The \text{ARITH} constraint holds since all values of the collection \( 4, 5, 7, 4, 5 \) are strictly less than 9.

**All solutions**  
Figure 5.89 gives all solutions to the following non ground instance of the \text{ARITH} constraint: \( V_1 \in [0,5], V_2 \in [2,3], V_3 \in [2,4], V_4 \in [1,6], \text{ARITH}(V_1, V_2, V_3, V_4), \leq, 2 \).

Figure 5.89: All solutions corresponding to the non ground example of the \text{ARITH} constraint of the All solutions slot

**Typical**  
- \(|\text{VARIABLES}| > 1\)
- \( \text{RELOP} \in [=] \)

**Symmetries**  
- Items of VARIABLES are permutable.
- An occurrence of a value of VARIABLES.var can be replaced by any value of VARIABLES.var.

**Arg. properties**  
Contractible wrt. VARIABLES.
Systems

![Hypergraph of the reformulation corresponding to the automaton of the ARITH constraint](image2)

**Figure 5.92:** Hypergraph of the reformulation corresponding to the automaton of the ARITH constraint
### 5.34 ARITH_OR

**Origin**

Used in the definition of several automata

**Constraint**

\[
\text{ARITH\_OR}(\text{VARIABLES1}, \text{VARIABLES2}, \text{RELOP}, \text{VALUE})
\]

**Arguments**

- \text{VARIABLES1} : collection(var\_dvar)
- \text{VARIABLES2} : collection(var\_dvar)
- \text{RELOP} : atom
- \text{VALUE} : int

**Restrictions**

- required(\text{VARIABLES1}, var)
- required(\text{VARIABLES2}, var)
- |\text{VARIABLES1}| = |\text{VARIABLES2}|
- \text{RELOP} \in \{=, \neq, <, \geq, >, \leq\}

**Purpose**

Enforce for all pairs of variables \(\text{var}_1, \text{var}_2\) of the \text{VARIABLES1} and \text{VARIABLES2} collections to have \(\text{var}_1 \text{RELOP} \text{VALUE} \lor \text{var}_2 \text{RELOP} \text{VALUE}\).

**Example**

\[
(\langle 0, 1, 0, 0 \rangle, \langle 0, 0, 1, 0 \rangle, =, 0)
\]

The constraint ARITH\_OR holds since, for all pairs of variables \(\text{var}_1, \text{var}_2\) of the \text{VARIABLES1} and \text{VARIABLES2} collections, there is at least one variable that is equal to 0.

**All solutions**

Figure 5.93 gives all solutions to the following non ground instance of the ARITH\_OR constraint:

\[
U_1 \in [3, 4], \; U_2 \in [1, 2], \; U_3 \in [1, 4], \; V_1 \in [2, 3], \; V_2 \in [2, 2], \; V_3 \in [0, 1],
\]

\[
\text{ARITH\_OR}(\langle U_1, U_2, U_3 \rangle, \langle V_1, V_2, V_3 \rangle, =, 2)
\]

**Typical**

- |\text{VARIABLES1}| > 0
- \text{RELOP} \in \{=\}

**Symmetries**

- Arguments are permutable w.r.t. permutation (\text{VARIABLES1}, \text{VARIABLES2}) (\text{RELOP}) (\text{VALUE}).
- Items of \text{VARIABLES1} and \text{VARIABLES2} are permutable (same permutation used).
**Arg. properties**

Contractible wrt. VARIABLES1 and VARIABLES2 (remove items from same position).

**See also**

specialisation: ARITH(variable RELOP VALUE ∨ variable RELOP VALUE replaced by variable RELOP VALUE).

**Keywords**

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

\texttt{ARITH\_SLIDING(VARIABLES, RELOP, VALUE)}

Arguments
\begin{itemize}
\item \texttt{VARIABLES} : \texttt{collection(var\textendash dvar)}
\item \texttt{RELOP} : \texttt{atom}
\item \texttt{VALUE} : \texttt{int}
\end{itemize}

Restrictions
\begin{itemize}
\item \texttt{RELOP} \in \{=, \neq, <, \geq, >, \leq\}
\end{itemize}

Purpose
Enforce for all sequences of variables \(\text{var}_1, \text{var}_2, \ldots, \text{var}_i (1 \leq i \leq |\text{VARIABLES}|)\) of the \texttt{VARIABLES} collection to have \((\text{var}_1 + \text{var}_2 + \cdots + \text{var}_i) \text{RELOP VALUE}\).

Example
\begin{itemize}
\item \((0, 0, 1, 2, 0, 0, -3), <, 4)\end{itemize}

The \texttt{ARITH\_SLIDING} constraint holds since all the following seven inequalities hold:
\begin{itemize}
\item \(0 < 4\),
\item \(0 + 0 < 4\),
\item \(0 + 0 + 1 < 4\),
\item \(0 + 0 + 1 + 2 < 4\),
\item \(0 + 0 + 1 + 2 + 0 < 4\),
\item \(0 + 0 + 1 + 2 + 0 + 0 < 4\),
\item \(0 + 0 + 1 + 2 + 0 + 0 - 3 < 4\).
\end{itemize}

All solutions
Figure 5.97 gives all solutions to the following non ground instance of the \texttt{ARITH\_SLIDING} constraint: \(V_1 \in [0, 5], V_2 \in [2, 3], V_3 \in [0, 4], \text{ARITH\_SLIDING}((V_1, V_2, V_3), \leq, 3)\).

\begin{itemize}
\item \((0, 2, 0), \leq, 3)\)
\item \((0, 2, 1), \leq, 3)\)
\item \((0, 3, 0), \leq, 3)\)
\item \((1, 2, 0), \leq, 3)\)
\end{itemize}

Figure 5.97: All solutions corresponding to the non ground example of the \texttt{ARITH\_SLIDING} constraint of the \textbf{All solutions} slot
**Typical**

- $|\text{VARIABLES}| > 1$
- $\text{RELOP} \in \{<, \geq, >, \leq\}$

**Arg. properties**

- Contractible wrt. $\text{VARIABLES}$ when $\text{RELOP} \in \{<, \leq\}$ and $\text{minval}(\text{VARIABLES}.\text{var}) \geq 0$.
- Suffix-contractible wrt. $\text{VARIABLES}$.

Automaton

Figure 5.98 depicts the automaton associated with the ARITH_SLIDING constraint. To each item of the collection VARIABLES corresponds a signature variable $S_i$ that is equal to 0.

Figure 5.98: Automaton of the ARITH_SLIDING constraint ($T$ is initially set to 1 and reset to 0 as soon as one of the sliding constraints does not hold)

Figure 5.99: Hypergraph of the reformulation corresponding to the automaton (with two counters) of the ARITH_SLIDING constraint (since all states of the automaton are accepting there is no restriction on the last variable $Q_n$)
5.36 ASSIGN_AND_COUNTS

Origin
N. Beldiceanu

Constraint
ASSIGN_AND_COUNTS(COLOURS, ITEMS, RELOP, LIMIT)

Arguments
COLOURS : collection(val=int)
ITEMS : collection(bin=dvar, colour=dvar)
RELOP : atom
LIMIT : dvar

Restrictions
required(COLOURS, val)
distinct(COLOURS, val)
required(ITEMS, [bin, colour])
RELOP ∈ [=, ≠, <, ≥, >, ≤]

Purpose
Given several items (each of them having a specific colour that may not be initially fixed), and different bins, assign each item to a bin, so that the total number \( n \) of items of colour \( \text{COLOURS} \) in each bin satisfies the condition \( n \ \text{RELOP} \ \text{LIMIT} \).

Example

\[
\begin{align*}
(4), \\
\text{bin} - 1 \text{ colour} - 4, \\
\text{bin} - 3 \text{ colour} - 4, \\
\text{bin} - 1 \text{ colour} - 4, \\
\text{bin} - 1 \text{ colour} - 5
\end{align*}
\]

Figure 5.100 shows the solution associated with the example. The items and the bins are respectively represented by little squares and by the different columns. Each little square contains the value of the key attribute of the item to which it corresponds. The items for which the colour attribute is equal to 4 are located under the thick line.

Figure 5.100: Assignment of the items to the bins

The ASSIGN_AND_COUNTS constraint holds since for each used bin (i.e., namely bins 1 and 3) the number of assigned items for which the colour attribute is equal to 4 is less than or equal to the limit 2.
All solutions

Figure 5.101 gives all solutions to the following non ground instance of the ASSIGN_AND_COUNTS constraint:

\[ B_1 \in [1, 2], \quad B_2 \in [2, 3], \quad B_3 \in [2, 3], \quad B_4 \in [3, 4], \quad C_1 \in [0, 1], \quad C_2 \in [0, 1], \quad C_3 \in [0, 0], \quad C_4 \in [0, 1], \]

ASSIGN_AND_COUNTS(\( \{0\} \), \( (B_1 \ C_1, \ B_2 \ C_2, \ B_3 \ C_3, \ B_4 \ C_4) \), \( \geq 3 \)).

1. \( \{1 \ 1, \ 3 \ 0, \ 3 \ 0, \ 3 \ 0\}, \geq 3 \)
2. \( \{2 \ 0, \ 2 \ 0, \ 2 \ 0, \ 3 \ 1\}, \geq 3 \)
3. \( \{2 \ 0, \ 2 \ 0, \ 2 \ 0, \ 4 \ 1\}, \geq 3 \)
4. \( \{2 \ 1, \ 3 \ 0, \ 3 \ 0, \ 3 \ 0\}, \geq 3 \)

Figure 5.101: All solutions corresponding to the non ground example of the ASSIGN_AND_COUNTS constraint of the All solutions slot, where items that are assigned colour 0 are shown in orange.

Typical

- \(|\text{COLOURS}| > 0\)
- \(|\text{ITEMS}| > 1\)
- \(\text{range}(\text{ITEMS.bin}) > 1\)
- \(\text{RELOP} \in [<, \leq]\)
- \(\text{LIMIT} > 0\)
- \(\text{LIMIT} < |\text{ITEMS}|\)

Symmetries

- Items of COLOURS are permutable.
- Items of ITEMS are permutable.
- All occurrences of two distinct values of ITEMS.bin can be swapped; all occurrences of a value of ITEMS.bin can be renamed to any unused value.

Arg. properties

- Contractible wrt. ITEMS when RELOP \(\in [<, \leq]\).
- Extensible wrt. ITEMS when RELOP \(\in [\geq, >]\).

Usage

Some persons have pointed out that it is impossible to use constraints such as AMONG, ATLEAST, ATMOST, COUNT, or GLOBAL_CARDINALITY if the set of variables is not initially known. For example, this is required in practice for some timetabling problems.

See also

- assignment dimension removed: COUNT, COUNTS.
- used in graph description: COUNTS.

Keywords

- application area: assignment.
- characteristic of a constraint: coloured, automaton, automaton with array of counters, derived collection.

Arc arity 2
Arc constraint(s) \( \text{items1.bin} = \text{items2.bin} \)
Graph class
- ACYCLIC
- BIPARTITE
- NO_LOOP
Sets
\[
\text{SUCC} \mapsto \begin{bmatrix}
\text{source,} \\
\text{variables} \in \text{col}(\text{VARIABLES-col}(\text{var-dvar}), [\text{item}(\text{var-}\text{ITEMS-colour})])
\end{bmatrix}
\]
Constraint(s) on sets \( \text{COUNTS}(\text{VALUES, variables, RELOP, LIMIT}) \)

Graph model
We enforce the \( \text{COUNTS} \) constraint on the colour of the items that are assigned to the same bin.

Parts (A) and (B) of Figure 5.102 respectively show the initial and final graph associated with the Example slot. The final graph consists of the following two connected components:

- The connected component containing six vertices corresponds to the items that are assigned to bin 1.
- The connected component containing two vertices corresponds to the items that are assigned to bin 3.

(A) (B)

Figure 5.102: Initial and final graph of the ASSIGN_AND_COUNTS constraint
The ASSIGN_AND_COUNTS constraint holds since for each set of successors of the vertices of the final graph no more than two items take colour 4.
Figure 5.103 depicts the automaton associated with the \textit{ASSIGN\_AND\_COUNTS} constraint. To each \texttt{COLOUR}_i of the collection \texttt{ITEMS} corresponds a 0-1 signature variable \texttt{S}_i. The following signature constraint links \texttt{COLOUR}_i and \texttt{S}_i: \texttt{COLOUR}_i \in \texttt{COLOURS} \Leftrightarrow \texttt{S}_i. For all items of the collection \texttt{ITEMS} for which the \texttt{COLOUR} attribute takes its value in \texttt{COLOURS}, counts for each value assigned to the \texttt{BIN} attribute its number of occurrences \texttt{n}, and finally imposes the condition \texttt{n} \texttt{RELOP LIMIT}.

\begin{verbatim}
NOT\_IN(\texttt{COLOUR}_i, \texttt{COLOURS})
\{\texttt{C}[i] \leftarrow 0\}
\IN(\texttt{COLOUR}_i, \texttt{COLOURS}),
\{\texttt{C}[\texttt{BIN}_i] \leftarrow \texttt{C}[\texttt{BIN}_i] + 1\}
\ARITH(\texttt{C}, \texttt{RELOP}, \texttt{LIMIT})
\end{verbatim}

Figure 5.103: Automaton of the \textit{ASSIGN\_AND\_COUNTS} constraint
### 5.37 ASSIGN_AND_NVALUES

#### Description

Origin
- Derived from `ASSIGN_AND_COUNTS` and `NVALUES`.

Constraint
- `ASSIGN_AND_NVALUES(ITEMS, RELOP, LIMIT)`

Arguments
- `ITEMS : collection(bin−dvar, value−dvar)`
- `RELOP : atom`
- `LIMIT : dvar`

Restrictions
- `required(ITEMS, [bin, value])`
- `RELOP ∈ [=, ≠, <, ≥, >, ≤]`

Purpose
- Given several items (each of them having a specific value that may not be initially fixed), and different bins, assign each item to a bin, so that the number $n$ of distinct values in each bin satisfies the condition $n \, RELOP \, LIMIT$.

Example

```
( bin − 2, value − 3, 
  bin − 1, value − 5, 
  bin − 2, value − 3, 
  bin − 2, value − 3, 
  bin − 2, value − 4 ) \leq 2
```

Figure 5.104 depicts the solution corresponding to the example.

#### Diagram

**Figure 5.104**: An assignment with at most two distinct values in parallel (values 3 and 4 in bin 2 and value 5 in bin 1)

The `ASSIGN_AND_NVALUES` constraint holds since for each used bin (i.e., namely bins 1 and 2) the number of distinct colours of the corresponding assigned items is less than or equal to the limit 2.
ASSIGN_AND_NVALUES

Typical

\[
|\text{ITEMS}| > 1 \\
\text{range}(\text{ITEMS}.\text{bin}) > 1 \\
\text{range}(\text{ITEMS}.\text{value}) > 1 \\
\text{RELOP} \in [<, \leq] \\
\text{LIMIT} > 1 \\
\text{LIMIT} < |\text{ITEMS}|
\]

Symmetries

- Items of \text{ITEMS} are permutable.
- All occurrences of two distinct values of \text{ITEMS}.\text{bin} can be swapped; all occurrences of a value of \text{ITEMS}.\text{bin} can be renamed to any unused value.

Arg. properties

- Contractible wrt. \text{ITEMS} when \text{RELOP} \in [<, \leq].
- Extensible wrt. \text{ITEMS} when \text{RELOP} \in [\geq, >].

Usage

Let us give two examples where the ASSIGN_AND_NVALUES constraint is useful:

- Quite often, in bin-packing problems, each item has a specific type, and one wants to assign items of similar type to each bin.
- In a vehicle routing problem, one wants to restrict the number of towns visited by each vehicle. Note that several customers may be located at the same town. In this example, each bin would correspond to a vehicle, each item would correspond to a visit to a customer, and the colour of an item would be the location of the corresponding customer.

See also

- assignment dimension removed: \text{NVALUE}, \text{NVALUES}.
- common keyword: \text{NVALUES_EXCEPT_0} \text{(number of distinct values)}.
- related: \text{ROOTS}.
- used in graph description: \text{NVALUES}.

Keywords

- application area: assignment.
- final graph structure: acyclic, bipartite, no loop.
- modelling: assignment dimension, number of distinct values.
Arc input(s): ITEMS ITEMS  
Arc generator: \( PRODUCT \rightarrow \text{collection}(\text{items1}, \text{items2}) \)  
Arc arity: 2  
Arc constraint(s): \( \text{items1.bin} = \text{items2.bin} \)  
Graph class:  
- ACYCLIC  
- BIPARTITE  
- NO_LOOP  
Sets:  
- \( \text{SUCC} \rightarrow \)  
  - source,  
  - variables – col(\( \text{VARIABLES-col}\)lection(\( \text{var-dvar} \)), \( \text{item}[(\text{var-ITEMS.value})] \))  
Constraint(s) on sets: \( \text{NVALUES}(\text{variables.RELOP, LIMIT}) \)  

Graph model:  
We enforce the \( \text{NVALUES} \) constraint on the items that are assigned to the same bin.  

Parts (A) and (B) of Figure 5.105 respectively show the initial and final graph associated with the Example slot. The final graph consists of the following two connected components:  
- The connected component containing 8 vertices corresponds to the items that are assigned to bin 2.  
- The connected component containing 2 vertices corresponds to the items that are assigned to bin 1.  

![Diagram](image)  

(A) (B)  

Figure 5.105: Initial and final graph of the ASSIGN_AND_NVALUES constraint  
The ASSIGN_AND_NVALUES constraint holds since for each set of successors of the vertices of the final graph no more than two distinct values are used:  
- The unique item assigned to bin 1 uses value 5.
• Items assigned to bin 2 use values 3 and 4.
## 5.38 ATLEAST

### Description

**Origin**: CHIP

**Constraint**: \( \text{ATLEAST}(N, \text{VARIABLES}, \text{VALUE}) \)

**Synonym**: COUNT.

**Arguments**

- \( N \) : int
- \( \text{VARIABLES} \) : collection(var–dvar)
- \( \text{VALUE} \) : int

**Restrictions**

- \( N \geq 0 \)
- \( N \leq \| \text{VARIABLES} \| \)
- \( \text{required}(\text{VARIABLES}, \text{var}) \)

**Purpose**

At least \( N \) variables of the \( \text{VARIABLES} \) collection are assigned value \( \text{VALUE} \).

**Example**

\[(2, \langle 4, 2, 4, 5 \rangle, 4)\]

The ATLEAST constraint holds since at least 2 values of the collection \( \langle 4, 2, 4, 5 \rangle \) are equal to value 4.

### All solutions

Figure 5.106 gives all solutions to the following non ground instance of the ATLEAST constraint:

\( V_1 \in [3, 5], V_2 \in [1, 2], V_3 \in [5, 6], V_4 \in [7, 9], \text{ATLEAST}(2, (V_1, V_2, V_3, V_4), 5) \).

![Figure 5.106: All solutions corresponding to the non ground example of the ATLEAST constraint of the All solutions slot](image)

### Typical

- \( N > 0 \)
- \( N < \| \text{VARIABLES} \| \)
- \( \| \text{VARIABLES} \| > 1 \)

### Symmetries

- Items of \( \text{VARIABLES} \) are permutable.
- \( N \) can be decreased to any value \( \geq 0 \).
- An occurrence of a value of \( \text{VARIABLES}.\text{var} \) that is different from \( \text{VALUE} \) can be replaced by any other value.
**Arg. properties**  
Extensible wrt. VARIABLES.

**Systems**  
OCCURRENCE_MIN in Choco, COUNT in Gecode, ATLEAST in Gecode, COUNT in JaCoP, AT_LEAST in MiniZinc, COUNT in SICStus.

**Used in**  
ALLDIFFERENT_EXCEPT_0, AMONG_DIFF_0, ATMOST, INT_VALUE_PRECEDE, ITH_POS_DIFFERENT_FROM_0, MINIMUM_EXCEPT_0, NVALUES_EXCEPT_0, PERIOD_EXCEPT_0, SLIDING_CARD_SKIP_0, WEIGHTED_PARTIAL_ALLDIFF.

**See also**  
common keyword: AMONG (value constraint).
comparison swapped: ATMOST.
implied by: EXACTLY (≥ N replaced by = N).
related: ROOTS.
soft variant: OPEN_ATLEAST (open constraint).

**Keywords**  
characteristic of a constraint: automaton, automaton with counters.
constraint network structure: alpha-acyclic constraint network(2).
constraint type: value constraint.
filtering: arc-consistency.
modelling: at least.
### Arc input(s)

| VARIABLES |

### Arc generator

`SELF -> \text{collection}(\text{variables})`

### Arc arity

1

### Arc constraint(s)

variables.var = VALUE

### Graph property(ies)

NARC \geq N

### Graph model

Since each arc constraint involves only one vertex (VALUE is fixed), we employ the \emph{SELF} arc generator in order to produce a graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.107 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the NARC graph property, the loops of the final graph are stressed in bold.

![Figure 5.107: Initial and final graph of the ATLEAST constraint](image-url)
Figure 5.108 depicts the automaton associated with the ATLEAST constraint. To each variable \( \text{VAR}_i \) of the collection \( \text{VARIABLES} \) corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i = \text{VALUE} \iff S_i \). The automaton counts the number of variables of the \( \text{VARIABLES} \) collection that are assigned value \( \text{VALUE} \) and finally checks that this number is greater than or equal to \( N \).

\[
\text{VAR}_i \neq \text{VALUE} \\
\{ C \leftarrow 0 \} \quad \{ \text{VAR}_i = \text{VALUE}, C \leftarrow C + 1 \}
\]

\[\text{ARITH}(N \leq C)\]

Figure 5.108: Automaton of the ATLEAST constraint.

Figure 5.109: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the ATLEAST constraint: since all states variables \( Q_0, Q_1, \ldots, Q_n \) are fixed to the unique state \( s \) of the automaton, the transitions constraints share only the counter variable \( C \) and the constraint network is Berge-acyclic.
5.39 ATLEAST_NVALUE

### Origin
[352]

### Constraint
ATLEAST_NVALUE(NVAL, VARIABLES)

### Synonym
K_DIFF.

### Arguments
- NVAL : dvar
- VARIABLES : collection(var−dvar)

### Restrictions
- required(VARIABLES, var)
- NVAL ≥ 0
- NVAL ≤ |VARIABLES|
- NVAL ≤ range(VARIABLES.var)

### Purpose
The number of distinct values taken by the variables of the collection VARIABLES is greater than or equal to NVAL.

### Example
\[(2, (3, 1, 7, 1, 6))
(4, (3, 1, 7, 1, 6))
(5, (3, 1, 7, 0, 6))\]

The first ATLEAST_NVALUE constraint holds since the collection \((3, 1, 7, 1, 6)\) involves at least 2 distinct values (i.e., in fact 4 distinct values).

### All solutions
Figure 5.110 gives all solutions to the following non ground instance of the ATLEAST_NVALUE constraint: NVAL ∈ \([3, 4]\), V₁ ∈ \([1, 2]\), V₂ = 3, V₃ ∈ \([3, 4]\), V₄ ∈ \([2, 3]\), ATLEAST_NVALUE(NVAL, \(\langle V₁, V₂, V₃, V₄ \rangle\)).

Figure 5.110: All solutions corresponding to the non ground example of the ATLEAST_NVALUE constraint of the All solutions slot

### Typical
- NVAL > 0
- NVAL < |VARIABLES|
- NVAL < range(VARIABLES.var)
- |VARIABLES| > 1
Typical model: \( nval(\text{VARIABLES}.\text{var}) > 2 \)

Symmetries:
- \( NVAL \) can be decreased to any value \( \geq 0 \).
- Items of \( \text{VARIABLES} \) are permutable.
- All occurrences of two distinct values of \( \text{VARIABLES}.\text{var} \) can be swapped; all occurrences of a value of \( \text{VARIABLES}.\text{var} \) can be renamed to any unused value.

Arg. properties: Extensible wrt. \( \text{VARIABLES} \).

Remark:
The \text{ATLEAST\_NVALUE} constraint was first introduced by J.-C. Régis under the name \text{k\_DIFF} in \cite{Regin:2000}. Later on the \text{ATLEAST\_NVALUE} constraint was introduced together with the \text{ATMOST\_NVALUE} constraint by C. Bessière et al. in an article \cite{Bessiere:2004} providing filtering algorithms for the \text{NVALUE} constraint.

Algorithm: \cite{Bessiere:2004} provides a sketch of a filtering algorithm enforcing arc-consistency for the \text{ATLEAST\_NVALUE} constraint. This algorithm is based on the maximal matching in a bipartite graph.

Solution count for `ATLEAST_NVALUE`: domains `0..n`
See also

- **comparison swapped**: `ATMOST_NVALUE`.
- **implied by**: `AND`, `EQUIVALENT`, `IMPLY`, `NAND`, `NOR`, `NVALUE` (\(\geq NVAL\)), `NVISIBLE_FROM_END`, `NVISIBLE_FROM_START`, `OR`,

---

The graphs show the solution density for `ATLEAST_NVALUE` for different sizes (6, 7, 8) as a function of the parameter value as a fraction of length. The observed density decreases as the parameter value increases.
uses in its reformulation: NOT_ALL_EQUAL.

**Keywords**

constraint type: counting constraint, value partitioning constraint.
filtering: bipartite matching, arc-consistency.
final graph structure: strongly connected component, equivalence.
modelling: number of distinct equivalence classes, number of distinct values.
### Graph model

Parts (A) and (B) of Figure 5.111 respectively show the initial and final graph associated with the first example of the **Example** slot. Since we use the **NSCC** graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a specific value that is assigned to some variables of the **VARIABLES** collection. The 4 following values 1, 3, 6 and 7 are used by the variables of the **VARIABLES** collection.
Figure 5.111: Initial and final graph of the ATLEAST_NVALUE constraint
5.40 ATLEAST_NVECTOR

Origin
Derived from NVECTOR

Constraint
ATLEAST_NVECTOR(NVEC, VECTORS)

Type
VECTOR : collection(var−dvar)

Arguments
NVEC : dvar
VECTORS : collection(vec − VECTOR)

Restrictions
|VECTOR| ≥ 1
NVEC ≥ 0
NVEC ≤ |VECTORS|
required(VECTORS, vec)
same_size(VECTORS, vec)

Purpose
The number of distinct tuples of values taken by the vectors of the collection VECTORS is greater than or equal to NVEC. Two tuples of values \(\langle A_1, A_2, \ldots, A_m \rangle\) and \(\langle B_1, B_2, \ldots, B_m \rangle\) are distinct if and only if there exist an integer \(i \in [1, m]\) such that \(A_i \neq B_i\).

Example
\[
\begin{pmatrix}
  \text{vec} - (5, 6), \\
  \text{vec} - (5, 6), \\
  \text{vec} - (9, 3), \\
  \text{vec} - (5, 6), \\
  \text{vec} - (9, 4)
\end{pmatrix}
\]

The ATLEAST_NVECTOR constraint holds since the collection VECTORS involves at least 2 distinct tuples of values (i.e., in fact the 3 distinct tuples \((5, 6), (9, 3)\) and \((9, 4)\)).

Typical
|VECTOR| > 1
NVEC > 1
NVEC < |VECTORS|
|VECTORS| > 1

Symmetries
- NVEC can be decreased to any value \(\geq 0\).
- Items of VECTORS are permutable.
- Items of VECTORS.vec are permutable (same permutation used).
- All occurrences of two distinct tuples of values of VECTORS.vec can be swapped; all occurrences of a tuple of values of VECTORS.vec can be renamed to any unused tuple of values.
### ATLEAST_NVECTOR

**Arg. properties**

Extensible wrt. VECTORS.

**Reformulation**

By introducing an extra variable $NV \in [0, |VECTORS|]$, the ATLEAST_NVECTOR($NV$, VECTORS) constraint can be expressed in term of an NVECTOR($NV$, VECTORS) constraint and of an inequality constraint $NV \geq NVEC$.

**See also**

- comparison swapped: ATMOST_NVECTOR.
- implied by: NVECTOR ($\geq NVEC$ replaced by $= NVEC$), ORDERED_ATLEAST_NVECTOR.
- used in graph description: LEX_EQUAL.

**Keywords**

- characteristic of a constraint: vector.
- constraint type: counting constraint, value partitioning constraint.
- final graph structure: strongly connected component, equivalence.
- modelling: number of distinct equivalence classes.
- problems: domination.
Arc input(s)  VECTORS
Arc generator  \( CLIQUE \rightarrow collection(vectors1, vectors2) \)
Arc arity  2
Arc constraint(s)  \( LEX\_EQUAL(vectors1\_vec, vectors2\_vec) \)
Graph property(ies)  \( NSCC \geq NVEC \)
Graph class  \( EQUIVALENCE \)

Graph model

Parts (A) and (B) of Figure 5.112 respectively show the initial and final graph associated with the Example slot. Since we use the NSCC graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a tuple of values that is assigned to some vectors of the VECTORS collection. The 3 following tuple of values \( \langle 5, 6 \rangle, \langle 9, 3 \rangle \) and \( \langle 9, 4 \rangle \) are used by the vectors of the VECTORS collection.

</tr>
</thead>
</table>

**Origin**
CHIP

**Constraint**
ATMOST(N, VARIABLES, VALUE)

**Synonym**
COUNT.

**Arguments**
- N : int
- VARIABLES : collection(var – dvar)
- VALUE : int

**Restrictions**
- \( N \geq 0 \)
- required(VARIABLES, var)

**Purpose**
At most \( N \) variables of the VARIABLES collection are assigned value VALUE.

**Example**
\((1, (4, 2, 4, 5), 2)\)

The ATMOST constraint holds since at most 1 value of the collection \((4, 2, 4, 5)\) is equal to value 2.

**All solutions**
Figure 5.113 gives all solutions to the following non ground instance of the ATMOST constraint: \( V_1 \in [1, 2], V_2 \in [2, 3], V_3 \in [5, 6], V_4 \in [2, 3], ATMOST(1, (V_1, V_2, V_3, V_4), 2) \).

![Figure 5.113](image)

**Typical**
- \( N > 0 \)
- \( N < |VARIABLES| \)
- \( |VARIABLES| > 1 \)

**ATLEAST(1, VARIABLES, VALUE)**

**Symmetries**
- Items of VARIABLES are permutable.
- \( N \) can be increased.
- An occurrence of a value of VARIABLES.var can be replaced by any other value that is different from VALUE.
### Arg. properties
Contractible wrt. VARIABLES.

### Systems
- OCCURRENCE\textsc{Max} in Choco,

- **implied by:** EXACTLY ($\leq N$ replaced by $=N$).
- **related:** ROOTS.
- **soft variant:** OPEN\_AT\textsc{Most} (open constraint).

### Keywords
- **characteristic of a constraint:** automaton, automaton with counters.
- **constraint network structure:** alpha-acyclic constraint network(2).
- **constraint type:** value constraint.
- **filtering:** arc-consistency.
- **modelling:** at most.
Arc input(s) | VARIABLES
---|---
Arc generator | \(SELF \mapsto \text{collection(variables)}\)
Arc arity | 1
Arc constraint(s) | \(\text{variables.var} = \text{VALUE}\)
Graph property(ies) | \(\text{NARC} \leq N\)

Graph model

Since each arc constraint involves only one vertex (VALUE is fixed), we employ the \(SELF\) arc generator in order to produce a graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.114 respectively show the initial and final graph associated with the Example slot. Since we use the \text{NARC} graph property, the loops of the final graph are stressed in bold.

![Graph](image)

**Figure 5.114:** Initial and final graph of the ATMOST constraint
Figure 5.115 depicts the automaton associated with the ATMOST constraint. To each variable $\text{VAR}_i$ of the collection $\text{VARIABLES}$ corresponds a 0-1 signature variable $S_i$. The following signature constraint links $\text{VAR}_i$ and $S_i$: $\text{VAR}_i = \text{VALUE} \iff S_i$. The automaton counts the number of variables of the $\text{VARIABLES}$ collection that are assigned value $\text{VALUE}$ and finally checks that this number is less than or equal to $\text{N}$.

\[
\text{ARITH}(\text{N}, \geq, C) \\
\{ C \leftarrow 0 \} \quad \{ \text{VAR}_i = \text{VALUE}, \ C \leftarrow C + 1 \} \\
\]

Figure 5.115: Automaton of the ATMOST constraint

Figure 5.116: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the ATMOST constraint: since all states variables $Q_0, Q_1, \ldots, Q_n$ are fixed to the unique state $s$ of the automaton, the transitions constraints share only the counter variable $C$ and the constraint network is Berge-acyclic.
5.42 ATMOST1

Origin [376]
Constraint ATMOST1(SETS)
Synonym PAIR_ATMOST1.
Argument SETS : collection(s−svar,c−int)
Restrictions required(SETS, [s, c])
SETS.c ≥ 1

Purpose

Given a collection of set variables \( s_1, s_2, \ldots, s_n \) and their respective cardinalities \( c_1, c_2, \ldots, c_n \), the ATMOST1 constraint forces the following two conditions:

- \( \forall i \in [1, n] : |s_i| = c_i \),
- \( \forall i, j \in [1, n] (i < j) : |s_i \cap s_j| \leq 1 \).

Example

\[
\begin{pmatrix}
  s & \{5, 8\} & c = 2, \\
  s & \{5\} & c = 1, \\
  s & \{5, 6, 7\} & c = 3, \\
  s & \{1, 4\} & c = 2
\end{pmatrix}
\]

The ATMOST1 constraint holds since:

- \(|\{5, 8\}| = 2, |\{5\}| = 1, |\{5, 6, 7\}| = 3, |\{1, 4\}| = 2.
- \(|\{5, 8\} \cap \{5\}| \leq 1, |\{5, 8\} \cap \{5, 6, 7\}| \leq 1, |\{5, 8\} \cap \{1, 4\}| \leq 1, \\
  |\{5\} \cap \{5, 6, 7\}| \leq 1, |\{5\} \cap \{1, 4\}| \leq 1, \\
  |\{5, 6, 7\} \cap \{1, 4\}| \leq 1.

Typical |SETS| > 1

Symmetries

- Items of SETS are permutable.
- All occurrences of two distinct values of SETS.a can be swapped; all occurrences of a value of SETS.a can be renamed to any unused value.

Arg. properties Contractible wrt. SETS.

Remark When we have only two set variables the ATMOST1 constraint was called PAIR_ATMOST1 in [439].
C. Bessière et al. have shown in [74] that it is NP-hard to enforce bound consistency for the ATMOST1 constraint. Consequently, following the first filtering algorithm from A. Sadler and C. Gervet [376], W.-J. van Hoeve and A. Sabharwal have proposed an algorithm that enforces bound-consistency when the ATMOST1 constraint involves only two sets variables [439].

**Systems**

ATMOST1 in MiniZinc.

**Keywords**

- **constraint arguments**: constraint involving set variables.
- **constraint type**: predefined constraint.
- **filtering**: bound-consistency.
5.43 ATMOST\_NVALUE

Origin

[68]

Constraint

\textbf{ATMOST\_NVALUE(NVAL, VARIABLES)}

Synonyms

\texttt{SOFT\_ALLDIFF\_MAX\_VAR, SOFT\_ALLDIFFERENT\_MAX\_VAR, SOFT\_ALLDISTINCT\_MAX\_VAR.}

Arguments

\begin{itemize}
  \item \texttt{NVAL} : dvar
  \item \texttt{VARIABLES} : collection(var−dvar)
\end{itemize}

Restrictions

\begin{itemize}
  \item \texttt{NVAL} \geq \text{min}(1,|VARIABLES|)
  \item \texttt{required(VARIABLES, var)}
\end{itemize}

Purpose

The number of distinct values taken by the variables of the collection VARIABLES is less than or equal to NVAL.

Example

\begin{itemize}
  \item (4, (3, 1, 3, 1, 6))
  \item (3, (3, 1, 3, 1, 6))
  \item (1, (3, 3, 3, 3, 3))
\end{itemize}

The first \textbf{ATMOST\_NVALUE} constraint holds since the collection (3, 1, 3, 1, 6) involves at most 4 distinct values (i.e., in fact 3 distinct values).

Typical

\begin{itemize}
  \item \texttt{NVAL} > 1
  \item \texttt{NVAL} < |VARIABLES|
  \item |VARIABLES| > 1
\end{itemize}

Symmetries

\begin{itemize}
  \item \texttt{NVAL} can be increased.
  \item Items of VARIABLES are \texttt{permutable}.
  \item All occurrences of two distinct values of VARIABLES.var can be \texttt{swapped}; all occurrences of a value of VARIABLES.var can be \texttt{renamed} to any unused value.
  \item An occurrence of a value of VARIABLES.var can be \texttt{replaced} by any value of VARIABLES.var.
\end{itemize}

Arg. properties

Contractible wrt. VARIABLES.

Remark

This constraint was introduced together with the \textbf{ATLEAST\_NVALUE} constraint by C. Bessière \textit{et al.} in an article [68] providing filtering algorithms for the \texttt{NVALUE} constraint.

It was shown in [75] that, finding out whether a \textbf{ATMOST\_NVALUE} constraint has a solution or not is NP-hard. This was achieved by reduction from \textbf{3-SAT.}
Algorithm [29] provides an algorithm that achieves bound consistency. [46] provides two filtering algorithms, while [68] provides a greedy algorithm and a graph invariant for evaluating the minimum number of distinct values. [68] also gives a linear relaxation for approximating the minimum number of distinct values.

Parts (A) and (B) of Figure 5.118 respectively show the initial and final graph associated with the Example slot. Since we use the NSCC graph property we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a tuple of values that is assigned to some vectors of the VECTORS collection. The 2 following tuple of values $\langle 5, 6 \rangle$ and $\langle 9, 3 \rangle$ are used by the vectors of the VECTORS collection.

Figure 5.118: Initial and final graph of the ATMOST_NVVECTOR constraint
ATMOST_NV ECTOR
5.45 BALANCE

Origin
N. Beldiceanu

Constraint
BALANCE(BALANCE, VARIABLES)

Arguments
BALANCE : dvar
VARIABLES : collection(var−dvar)

Restrictions
BALANCE ≥ 0
BALANCE ≤ max(0, |VARIABLES| − 2)
required(VARIABLES, var)

Purpose
BALANCE is equal to the difference between the number of occurrence of the value that occurs the most and the value that occurs the least within the collection of variables VARIABLES.

Example
(2, (3, 1, 7, 1, 1))
(0, (3, 3, 1, 1, 1, 3))
(4, (3, 1, 1, 1, 1, 1))

In the first example, values 1, 3 and 7 are respectively used 3, 1 and 1 times. The corresponding BALANCE constraint holds since its first argument BALANCE is assigned to the difference between the maximum and minimum number of the previous occurrences (i.e., 3 − 1). Figure 5.119 shows the solution associated with this first example.

Figure 5.119: Illustration of the first example of the Example slot: five variables $V_1$, $V_2$, $V_3$, $V_4$, $V_5$ respectively fixed to values 3, 1, 7, 1 and 1, and the corresponding value of $BALANCE = 2$
Figure 5.120 gives all solutions to the following non ground instance of the \texttt{BALANCE} constraint: \texttt{BALANCE} $\in [2, 3]$, $\mathbf{V}_1 \in [0, 5]$, $\mathbf{V}_2 \in [2, 6]$, $\mathbf{V}_3 \in [0, 1]$, $\mathbf{V}_4 \in [1, 2]$, \texttt{BALANCE}(\texttt{BALANCE}, ($\mathbf{V}_1, \mathbf{V}_2, \mathbf{V}_3, \mathbf{V}_4$)).

Figure 5.120: All solutions corresponding to the non ground example of the \texttt{BALANCE} constraint of the \texttt{All solutions} slot

| Typical | \texttt{BALANCE} $\leq 2 + |\texttt{VARIABLES}|/10$  

| Typical model | \texttt{nval}($\texttt{VARIABLES}.\texttt{var}$) $> 2$ |

| Symmetries | Items of \texttt{VARIABLES} are permutable.

| Arg. properties | Functional dependency: \texttt{BALANCE} determined by \texttt{VARIABLES}.

| Usage | An application of the \texttt{BALANCE} constraint is to enforce a balanced assignment of values, no matter how many distinct values will be used. In this case one will push down the maximum value of the first argument of the \texttt{BALANCE} constraint.

| Remark | If we do not want to use an automaton with an array of counters a first possible reformulation of the \texttt{BALANCE} constraint introduced in [44, pages 1860–1861] can be achieved in the following way. We use a \texttt{SORT} constraint in order to reorder the variables of the collection...
VARIABLES and compute the difference between the longest and the smallest sequences of consecutive values.

A more efficient reformulation introduced in [45, page 2071] uses a GLOBAL CARDINALITY constraint for exposing the occurrence variables attached to each value that can possibly be assigned to the variables of the BALANCE constraint. Then the BALANCE argument is set to the difference between the maximum value of the occurrence variables and the minimum value of the occurrence variables that are different from 0.

Algorithm

It was shown in [77] that achieving arc-consistency on the BALANCE constraint is NP-hard.

<td>BALANCE</td>
<td>dvar</td>
</tr>
<tr>
<td>NODES</td>
<td>collection(index=int, succ=dvar)</td>
</tr>
</tbody>
</table>

**Restrictions**

- BALANCE \(\geq 0\)
- BALANCE \(\leq \max(0, |NODES| - 2)\)
- required(NODES,[index,succ])
- NODES.index \(\geq 1\)
- NODES.index \(\leq |NODES|\)
- distinct(NODES,index)
- NODES.succ \(\geq 1\)
- NODES.succ \(\leq |NODES|\)

**Purpose**

Consider a digraph \(G\) described by the NODES collection. Partition \(G\) into a set of vertex disjoint circuits in such a way that each vertex of \(G\) belongs to a single circuit. BALANCE is equal to the difference between the number of vertices of the largest circuit and the number of vertices of the smallest circuit.

**Example**

In the first example we have the following two circuits: \(1 \rightarrow 2 \rightarrow 1\) and \(3 \rightarrow 5 \rightarrow 4 \rightarrow 3\). Since BALANCE = 1 is the difference between the number of vertices of the largest circuit (i.e., 3) and the number of vertices of the smallest circuit (i.e., 2) the corresponding BALANCE_CYCLE constraint holds.
Figure 5.123 gives all solutions to the following non ground instance of the BALANCE_CYCLE constraint: BALANCE ∈ [0, 1], S₁ ∈ [1, 2], S₂ ∈ [1, 3], S₃ ∈ [3, 5], S₄ ∈ [3, 4], S₅ ∈ [2, 5], BALANCE_CYCLE(BALANCE, (1 S₁, 2 S₂, 3 S₃, 4 S₄, 5 S₅)).

Figure 5.123: All solutions corresponding to the non ground example of the BALANCE_CYCLE constraint of the All solutions slot; the index attribute is displayed as indices of the succ attribute, and all vertices of a same cycle are coloured by the same colour; the bottom left part of each subfigure shows how the BALANCE argument (in red) is related to the largest and to the smallest cycles.

Typical | \(|\text{NODES}| > 2\)

Symmetry | Items of NODES are permutable.

Arg. properties | Functional dependency: BALANCE determined by NODES.

### Solution density for `BALANCE_CYCLE`

![Graph showing solution density for `BALANCE_CYCLE` with parameter value as fraction of length]
See also **related**: BALANCE (equivalence classes correspond to vertices in same cycle rather than variables assigned to the same value), CYCLE (do not care how many cycles but how balanced the cycles are).

**Keywords**
- **combinatorial object**: permutation.
- **constraint type**: graph constraint, graph partitioning constraint.
- **filtering**: DFS-bottleneck.
- **final graph structure**: circuit, connected component, strongly connected component, one_succe.
- **modelling**: cycle, functional dependency.

**Cond. implications**
- \( \text{BALANCE\_CYCLE(\textit{BALANCE, NODES})} \) with \( \text{BALANCE} > 0 \) and \( \text{BALANCE} \leq 2 \) implies \( \text{ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS(} K : \text{BALANCE, VECTORS : NODES}) \).
- \( \text{BALANCE\_CYCLE(\textit{BALANCE, NODES})} \) implies \( \text{PERMUTATION(} \text{VARIABLES : NODES}) \).
From the restrictions and from the arc constraint, we deduce that we have a bijection from the successor variables to the values of interval $[1, |\text{NODES}|]$. With no explicit restrictions it would have been impossible to derive this property.

In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices. This is why the \text{BALANCE}_\text{CYCLE} constraint considers objects that have two attributes:

- One fixed attribute \text{index} that is the identifier of the vertex,
- One variable attribute \text{succ} that is the successor of the vertex.

The graph property \text{NTREE} = 0 is used in order to avoid having vertices that both do not belong to a circuit and have at least one successor located on a circuit. This concretely means that all vertices of the final graph should belong to a circuit.

Parts (A) and (B) of Figure 5.124 respectively show the initial and final graph associated with the first example of the \textbf{Example} slot. Since we use the \text{RANGE}_NCC graph property, we show the connected components of the final graph. The constraint holds since all the vertices belong to a circuit (i.e., \text{NTREE} = 0) and since \text{BALANCE} = \text{RANGE}_NCC = 1.
5.47 BALANCE_INTERVAL

<table>
<thead>
<tr>
<th>Origin</th>
<th>Derived from BALANCE.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constraint</td>
<td>BALANCE_INTERVAL(BALANCE, VARIABLES, SIZE_INTERVAL)</td>
</tr>
</tbody>
</table>
| Arguments | BALANCE : dvar  
VARIABLES : collection(var−dvar)  
SIZE_INTERVAL : int |
| Restrictions | BALANCE ≥ 0  
BALANCE ≤ max(0, |VARIABLES| − 2)  
required(VARIABLES, var)  
SIZE_INTERVAL > 0 |
| Purpose | Consider the largest set $S_1$ (respectively the smallest set $S_2$) of variables of the collection VARIABLES that take their values in a same interval $[\text{SIZE_INTERVAL} \cdot k, \text{SIZE_INTERVAL} \cdot k + \text{SIZE_INTERVAL} - 1]$, where $k$ is an integer. BALANCE is equal to the difference between the cardinality of $S_2$ and the cardinality of $S_1$. |
| Example | (3, (6, 4, 3, 3, 4), 3) |

In the example, the third argument $\text{SIZE_INTERVAL} = 3$ defines the following family of intervals $[3 \cdot k, 3 \cdot k + 2]$, where $k$ is an integer. Values 6, 4, 3, 3 and 4 are respectively located within intervals $[6, 8]$, $[3, 5]$, $[3, 5]$, $[3, 5]$ and $[3, 5]$. Therefore intervals $[6, 8]$ and $[3, 5]$ are respectively used 1 and 4 times. The BALANCE_INTERVAL constraint holds since its first argument BALANCE is assigned to the difference between the maximum and minimum number of the previous occurrences (i.e., $4 - 1$).

| Typical | $|\text{VARIABLES}| > 2$  
$\text{SIZE_INTERVAL} > 1$  
$\text{SIZE_INTERVAL} < \text{range}(\text{VARIABLES}.\text{var})$ |
| Symmetries | • Items of VARIABLES are permutable.  
• An occurrence of a value of VARIABLES.var that belongs to the $k$-th interval, of size $\text{SIZE_INTERVAL}$, can be replaced by any other value of the same interval. |
| Arg. properties | Functional dependency: BALANCE determined by VARIABLES and SIZE_INTERVAL. |
| Usage | An application of the BALANCE_INTERVAL constraint is to enforce a balanced assignment of interval of values, no matter how many distinct interval of values will be used. In this case one will push down the maximum value of the first argument of the BALANCE_INTERVAL constraint. |

specialisation: BALANCE (variable/constant replaced by variable).

Keywords

application area: assignment.
characteristic of a constraint: automaton, automaton with array of counters.
constraint arguments: pure functional dependency.
constraint type: value constraint.
final graph structure: equivalence.
modelling: interval, balanced assignment, functional dependency.
The graph property \texttt{RANGE\_NSCC} constrains the difference between the sizes of the largest and smallest strongly connected components.

Parts (A) and (B) of Figure 5.125 respectively show the initial and final graph associated with the \texttt{Example} slot. Since we use the \texttt{RANGE\_NSCC} graph property, we show the largest and smallest strongly connected components of the final graph.

**Figure 5.125: Initial and final graph of the BALANCE\_INTERVAL constraint**
Figure 5.126 depicts the automaton associated with the BALANCE INTERVAL constraint. To each item of the collection VARIABLES corresponds a signature variable $S_i$ that is equal to 1.

\[
\begin{align*}
\{C[.] \leftarrow 0\} & \quad \to & \quad \{C[\text{VAR}_i \text{SIZE}_\text{INTERVAL}] \leftarrow C[\text{VAR}_i \text{SIZE}_\text{INTERVAL}] + 1\} \\
\{\text{MINIMUM}_\text{EXCEPT}_0(N_1, C)\} & & \{\text{MAXIMUM}(N_2, C)\} \\
\text{BALANCE} = N_2 - N_1
\end{align*}
\]

Figure 5.126: Automaton of the BALANCE INTERVAL constraint
5.48 BALANCE_MODULO

Origin
Derived from BALANCE.

Constraint
BALANCE_MODULO(BALANCE, VARIABLES, M)

Arguments
- BALANCE : dvar
- VARIABLES : collection(var–dvar)
- M : int

Restrictions
- BALANCE ≥ 0
- BALANCE ≤ max(0, |VARIABLES| − 2)
- required(VARIABLES, var)
- M > 0

Purpose
Consider the largest set $S_1$ (respectively the smallest set $S_2$) of variables of the collection VARIABLES that have the same remainder when divided by M. BALANCE is equal to the difference between the cardinality of $S_2$ and the cardinality of $S_1$.

Example
(2, (6, 1, 7, 1, 5), 3)

In this example values 6, 1, 7, 1, 5 are respectively associated with the equivalence classes $6 \mod 3 = 0$, $1 \mod 3 = 1$, $7 \mod 3 = 1$, $1 \mod 3 = 1$, $5 \mod 3 = 2$. Therefore the equivalence classes 0, 1 and 2 are respectively used 1, 3 and 1 times. The BALANCE_MODULO constraint holds since its first argument BALANCE is assigned to the difference between the maximum and minimum number of the previous occurrences (i.e., $3 - 1$).

Typical
- |VARIABLES| > 2
- M > 1
- M < maxval(VARIABLES, var)

Symmetries
- Items of VARIABLES are permutable.
- An occurrence of a value $u$ of VARIABLES.var can be replaced by any other value $v$ such that $v$ is congruent to $u$ modulo M.

Arg. properties
Functional dependency: BALANCE determined by VARIABLES and M.

Usage
An application of the BALANCE_MODULO constraint is to enforce a balanced assignment of values, no matter how many distinct equivalence classes will be used. In this case one will push down the maximum value of the first argument of the BALANCE_MODULO constraint.

See also
specialisation: BALANCE(variable mod constant replaced by variable).
Keywords

- **constraint arguments**: pure functional dependency.
- **constraint type**: value constraint.
- **final graph structure**: equivalence.
- **modelling**: balanced assignment, functional dependency.
Graph model

The graph property `RANGE_NSCC` constrains the difference between the sizes of the largest and smallest strongly connected components.

Parts (A) and (B) of Figure 5.127 respectively show the initial and final graph associated with the Example slot. Since we use the `RANGE_NSCC` graph property, we show the largest and smallest strongly connected components of the final graph.

![Diagram](image)

Figure 5.127: Initial and final graph of the BALANCE_MODULO constraint
Figure 5.128 depicts the automaton associated with the BALANCE_MODULO constraint. To each item of the collection VARIABLES corresponds a signature variable $S_i$ that is equal to 1.

\[
\begin{align*}
\{C[.] \leftarrow 0\} & \quad 1, \\
\{C[\text{VAR}_i \mod M] \leftarrow C[\text{VAR}_i \mod M] + 1\}
\end{align*}
\]

Figure 5.128: Automaton of the BALANCE_MODULO constraint
### 5.49 BALANCE_PARTITION

**Origin**
Derived from BALANCE.

**Constraint**
BALANCE_PARTITION(BALANCE, VARIABLES, PARTITIONS)

**Type**
VALUES : collection(val−int)

**Arguments**
BALANCE : dvar
VARIABLES : collection(var−dvar)
PARTITIONS : collection(p – VALUES)

**Restrictions**

- \(|\text{VALUES}| \geq 1\)
- \(\text{required}(\text{VALUES}, \text{val})\)
- \(\text{distinct}(\text{VALUES}, \text{val})\)
- \(\text{BALANCE} \geq 0\)
- \(\text{BALANCE} \leq \max(0, |\text{VARIABLES}| - 2)\)
- \(\text{required}(\text{VARIABLES}, \text{var})\)
- \(\text{required}(\text{PARTITIONS}, \text{p})\)
- \(|\text{PARTITIONS}| \geq 2\)

**Purpose**
Consider the largest set \(\mathcal{S}_1\) (respectively the smallest set \(\mathcal{S}_2\)) of variables of the collection VARIABLES that take their values in the same partition of the collection PARTITIONS. BALANCE is equal to the difference between the cardinality of \(\mathcal{S}_2\) and the cardinality of \(\mathcal{S}_1\).

**Example**
\[(1, (6, 2, 6, 4, 4), (p - \{1, 3\}, p - \{4\}, p - \{2, 6\}))\]

In this example values 6, 2, 6, 4, 4 are respectively associated with the partitions \(p - \{2, 6\}\) and \(p - \{4\}\). Partitions \(p - \{4\}\) and \(p - \{2, 6\}\) are respectively used 2 and 3 times. The BALANCE_PARTITION constraint holds since its first argument BALANCE is assigned to the difference between the maximum and minimum number of the previous occurrences (i.e., 3 - 2). Note that we do not consider those partitions that are not used at all.

**Typical**

- \(|\text{VARIABLES}| > 2\)
- \(|\text{VARIABLES}| > |\text{PARTITIONS}|\)

**Symmetries**
- Items of VARIABLES are **permutable**.
- Items of PARTITIONS are **permutable**.
- Items of PARTITIONS, p are **permutable**.
- An occurrence of a value of VARIABLES, var can be replaced by any other value that also belongs to the same partition of PARTITIONS.
Arg. properties

- Functional dependency: BALANCE determined by VARIABLES and PARTITIONS.

Usage

An application of the BALANCE_PARTITION is to enforce a balanced assignment of values, no matter how many distinct partitions will be used. In this case one will push down the maximum value of the first argument of the BALANCE_PARTITION constraint.

See also

- specialisation: BALANCE\(\text{\text{variable} } \in \text{\text{partition replaced by variable}}\).
- used in graph description: IN\_SAME\_PARTITION.

Keywords

- application area: assignment.
- characteristic of a constraint: partition.
- constraint arguments: pure functional dependency.
- constraint type: value constraint.
- final graph structure: equivalence.
- modelling: balanced assignment, functional dependency.
Arc input(s): VARIABLES

Arc generator: $CLIQUE \rightarrow \text{collection}(\text{variables1,variables2})$

Arc constraint(s): $\text{IN\_SAME\_PARTITION}(\text{variables1.var,variables2.var,PARTITIONS})$

Graph property(ies): $\text{RANGE\_NSCC}=\text{BALANCE}$

Graph class: $\text{EQUIVALENCE}$

Graph model:
The graph property $\text{RANGE\_NSCC}$ constrains the difference between the sizes of the largest and smallest strongly connected components.

Parts (A) and (B) of Figure 5.129 respectively show the initial and final graph associated with the Example slot. Since we use the $\text{RANGE\_NSCC}$ graph property, we show the largest and smallest strongly connected components of the final graph.

Figure 5.129: Initial and final graph of the BALANCE\_PARTITION constraint
5.50 BALANCE_PATH

Origin

derived from BALANCE and PATH

Constraint

BALANCE_PATH(BALANCE, NODES)

Arguments

\[
\begin{align*}
\text{BALANCE} & : \text{dvar} \\
\text{NODES} & : \text{collection(index=int, succ=dvar)}
\end{align*}
\]

Restrictions

\[
\begin{align*}
\text{BALANCE} & \geq 0 \\
\text{BALANCE} & \leq \max(0, |\text{NODES}|-2) \\
\text{required}(\text{NODES}, [\text{index, succ}]) & \\
\text{NODES.index} & \geq 1 \\
\text{NODES.index} & \leq |\text{NODES}| \\
\text{distinct}(\text{NODES}, \text{index}) & \\
\text{NODES.succ} & \geq 1 \\
\text{NODES.succ} & \leq |\text{NODES}|
\end{align*}
\]

Purpose

Consider a digraph $G$ described by the NODES collection. Partition $G$ into a set of vertex disjoint paths in such a way that each vertex of $G$ belongs to a single path. BALANCE is equal to the difference between the number of vertices of the largest path and the number of vertices of the smallest path.
Example

In the first example we have the following four paths: 2 → 3 → 5 → 1, 8 → 6, 4, and 7. Since \( \text{BALANCE} = 3 \) is the difference between the number of vertices of the largest path (i.e., 4) and the number of vertices of the smallest path (i.e., 1) the corresponding \text{BALANCE_PATH} constraint holds.

All solutions

Figure 5.130 gives all solutions to the following non ground instance of the \text{BALANCE_PATH} constraint: \( \text{BALANCE} = 0, S_1 \in [1, 2], S_2 \in [1, 3], S_3 \in [3, 5], S_4 \in [3, 4], S_5 \in [2, 5], S_6 \in [5, 6], \text{BALANCE_PATH} (\text{BALANCE}, \langle 1 S_1, 2 S_2, 3 S_3, 4 S_4, 5 S_5, 6 S_6 \rangle). \)

Typical

\(|\text{NODES}| > 2\)

Symmetry

Items of \text{NODES} are permutable.

Arg. properties

Functional dependency: \text{BALANCE} determined by \text{NODES}.

Arc input(s)    NODES
Arc generator   $\text{CLIQUE} \rightarrow \text{collection}(\text{nodes}_1, \text{nodes}_2)$
Arc arity       2
Arc constraint(s)  $\text{nodes}_1.\text{succ} = \text{nodes}_2.\text{index}$
Graph property(ies)  
  * $\text{MAX_NSCC} \leq 1$
  * $\text{MAX_ID} \leq 1$
  * $\text{RANGE_NCC} = \text{BALANCE}$
Graph class      $\text{ONE_SUCC}$

Graph model
In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices. This is why the $\text{BALANCE\_PATH}$ constraint considers objects that have two attributes:

- One fixed attribute $\text{index}$ that is the identifier of the vertex,
- One variable attribute $\text{succ}$ that is the successor of the vertex.

We use the graph property $\text{MAX_NSCC} \leq 1$ in order to specify the fact that the size of the largest strongly connected component should not exceed one. In fact each root of a tree is a strongly connected component with a single vertex. The graph property $\text{MAX_ID} \leq 1$ constrains the maximum in-degree of the final graph to not exceed 1. $\text{MAX_ID}$ does not consider loops: This is why we do not have any problem with the final node of each path.

Parts (A) and (B) of Figure 5.131 respectively show the initial and final graph associated with the first example of the Example slot. Since we use the $\text{RANGE_NCC}$ graph property, we show the connected components of the final graph. The constraint holds since all the vertices belong to a path and since $\text{BALANCE} = \text{RANGE_NCC} = 3$.

![Figure 5.131: Initial and final graph of the $\text{BALANCE\_PATH}$ constraint](image)
5.51 BALANCE TREE

**Description**

Origin: derived from BALANCE and TREE

Constraint: \( \text{BALANCE_TREE}(\text{BALANCE, NODES}) \)

Arguments:
- \( \text{BALANCE} : \text{dvar} \)
- \( \text{NODES} : \text{collection(index-int, succ-dvar)} \)

Restrictions:
- \( \text{BALANCE} \geq 0 \)
- \( \text{BALANCE} \leq \max(0, |\text{NODES}| - 2) \)
- \( \text{required}(\text{NODES}, [\text{index}, \text{succ}]) \)
- \( \text{NODES.index} \geq 1 \)
- \( \text{NODES.index} \leq |\text{NODES}| \)
- \( \text{distinct}(\text{NODES, index}) \)
- \( \text{NODES.succ} \geq 1 \)
- \( \text{NODES.succ} \leq |\text{NODES}| \)

**Purpose**

Consider a digraph \( G \) described by the NODES collection. Partition \( G \) into a set of vertex disjoint trees in such a way that each vertex of \( G \) belongs to a single tree. \( \text{BALANCE} \) is equal to the difference between the number of vertices of the largest tree and the number of vertices of the smallest tree.

**Example**

In the first example we have two trees involving respectively the set of vertices \( \{1, 2, 3, 5, 6, 8\} \) and the set \( \{4, 7\} \). They are depicted by Figure 5.132. Since \( \text{BALANCE} = 6 - 2 = 4 \) is the difference between the number of vertices of the largest tree (i.e., 6) and the number of vertices of the smallest tree (i.e., 2) the corresponding BALANCE_TREE constraint holds.
Figure 5.132: The two trees associated with the first example of the Example slot, respectively containing 6 and 2 vertices, therefore $\text{BALANCE} = 6 - 2 = 4$; each vertex contains the information $\text{index} | \text{succ}$ where $\text{succ}$ is the index of its father in the tree (by convention the father of the root is the root itself).

All solutions

Figure 5.133 gives all solutions to the following non ground instance of the $\text{BALANCE_TREE}$ constraint: $\text{BALANCE} = 0$, $S_1 \in [1, 2]$, $S_2 \in [1, 2]$, $S_3 \in [4, 5]$, $S_4 \in [2, 4]$, $S_5 \in [4, 5]$, $S_6 \in [5, 6]$, $\text{BALANCE_TREE}(\text{BALANCE}, (1 S_1, 2 S_2, 3 S_3, 4 S_4, 5 S_5, 6 S_6))$.

Typical

$|\text{NODES}| > 2$

Symmetry

Items of $\text{NODES}$ are permutable.

Arg. properties

Functional dependency: $\text{BALANCE}$ determined by $\text{NODES}$.

---|---
Arc generator | \( \text{CLIQUE} \rightarrow \text{collection}(\text{nodes1}, \text{nodes2}) \)
Arc arity | 2
Arc constraint(s) | \( \text{nodes1.succ} = \text{nodes2.index} \)
Graph property(ies) | • \( \text{MAX\_NSCC} \leq 1 \)
| | • \( \text{RANGE\_NCC} = \text{BALANCE} \)

Graph model

In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices. This is why the \text{BALANCE\_TREE} constraint considers objects that have two attributes:

- One fixed attribute \text{index} that is the identifier of the vertex,
- One variable attribute \text{succ} that is the successor of the vertex.

We use the graph property \( \text{MAX\_NSCC} \leq 1 \) in order to specify the fact that the size of the largest strongly connected component should not exceed one. In fact each root of a tree is a strongly connected component with a single vertex.

Parts (A) and (B) of Figure 5.134 respectively show the initial and final graph associated with the first example of the \text{Example} slot. Since we use the \text{RANGE\_NCC} graph property, we show the connected components of the final graph. The constraint holds since all the vertices belong to a tree and since \( \text{BALANCE} = \text{RANGE\_NCC} 6 - 2 = 4 \).

![Figure 5.134: Initial and final graph of the BALANCE_TREE constraint](image-url)
BALANCE_TREE

763
5.52 BETWEEN_MIN_MAX

Origin
Used for defining CUMULATIVE_CONVEX.

Constraint
BETWEEN_MIN_MAX(VAR, VARIABLES)

Arguments
VAR : dvar
VARIABLES : collection(var−dvar)

Restrictions
required(VARIABLES, var)
|VARIABLES| > 0

Purpose
VAR is greater than or equal to at least one variable of the collection VARIABLES and less than or equal to at least one variable of the collection VARIABLES.

Example
(3, (1, 1, 4, 8))
(1, (1, 1, 4, 8))
(8, (1, 1, 4, 8))

The first BETWEEN_MIN_MAX constraint holds since its first argument 3 is greater than or equal to the minimum value of the values of the collection (1, 1, 4, 8) and less than or equal to the maximum value of (1, 1, 4, 8).

Typical
|VARIABLES| > 1
range(VARIABLES.var) > 1

Symmetries
- Items of VARIABLES are permutable.
- VAR can be set to any value of VARIABLES.var.

Arg. properties
Extensible wrt. VARIABLES.

Reformulation
By introducing two extra variables MIN and MAX, the BETWEEN_MIN_MAX(VAR, VARIABLES) constraint can be expressed in term of the following conjunction of constraints:
MINIMUM(MIN, VARIABLES),
MAXIMUM(MAX, VARIABLES),
VAR ≥ MIN,
VAR ≤ MAX.

### Graph model

Parts (A) and (B) of Figure 5.135 respectively show the initial and final graph associated with the second graph constraint of the first example of the Example slot. Since we use the NARC graph property, the two arcs of the final graph are stressed in bold. The constraint holds since 3 is greater than 1 and since 3 is less than 8.

![Graph model](image)

Figure 5.135: Initial and final graph of the BETWEEN_MIN_MAX constraint
Automaton

Figure 5.136 depicts the automaton associated with the BETWEEN_MIN_MAX constraint. To each pair $(\text{VAR}, \text{VAR}_i)$, where $\text{VAR}_i$ is a variable of the collection VARIABLES corresponds a signature variable $S_i$. The following signature constraint links $\text{VAR}, \text{VAR}_i$, and $S_i$: $(\text{VAR} < \text{VAR}_i \Leftrightarrow S_i = 0) \land (\text{VAR} = \text{VAR}_i \Leftrightarrow S_i = 1) \land (\text{VAR} > \text{VAR}_i \Leftrightarrow S_i = 2)$.

5.53 BIG_PEAK

Origin

Derived from PEAK.

Constraint

BIG_PEAK(N, VARIABLES, TOLERANCE)

Arguments

N : dvar
VARIABLES : collection(var−dvar)
TOLERANCE : int

Restrictions

N ≥ 0
2 * N ≤ max(|VARIABLES| − 1, 0)
required(VARIABLES, var)
TOLERANCE ≥ 0

A variable \( V_p \) (1 < \( p \) < \( m \)) of the sequence of variables \( \text{VARIABLES} = V_1, \ldots, V_m \) is a peak if and only if there exists an \( i \) (1 < \( i \) ≤ \( p \)) such that \( V_{i-1} < V_i \) and \( V_i = V_{i+1} = \cdots = V_p \) and \( V_p > V_{p+1} \). Similarly a variable \( V_v \) (1 < \( k \) < \( m \)) is a valley if and only if there exists an \( i \) (1 < \( i \) ≤ \( v \)) such that \( V_{i-1} > V_i \) and \( V_i = V_{i+1} = \cdots = V_v \) and \( V_v < V_{v+1} \). A peak variable \( V_p \) (1 < \( p \) < \( m \)) is a potential big peak wrt a non-negative integer TOLERANCE if and only if:

1. \( V_p \) is a peak,
2. \( \exists i, j \in [1, m] \mid i < p < j, V_i \) is a valley (or \( i = 1 \) if there is no valley before position \( p \)), \( V_j \) is a valley (or \( i = m \) if there is no valley after position \( p \)), \( V_p − V_i > \text{TOLERANCE} \), and \( V_p − V_j > \text{TOLERANCE} \).

Let \( i_p \) and \( j_p \) be the largest \( i \) and the smallest \( j \) satisfying condition 2. Now a potential big peak \( V_p \) (1 < \( p \) < \( m \)) is a big peak if and only if the interval [\( i_p, j_p \)] does not contain any potential big peak that is strictly higher than \( V_p \). The constraint BIG_PEAK holds if and only if \( N \) is the total number of big peaks of the sequence of variables \( \text{VARIABLES} \).

Example

\[
\begin{align*}
(7, \{4, 2, 2, 4, 3, 8, 6, 7, 7, 9, 5, 6, 3, 12, 12, 6, 6, 8, 4, 5, 1\}, 0) \\
(4, \{4, 2, 2, 4, 3, 8, 6, 7, 7, 9, 5, 6, 3, 12, 12, 6, 6, 8, 4, 5, 1\}, 1)
\end{align*}
\]

As shown part Part (A) of Figure 5.138, the first BIG_PEAK constraint holds since the sequence 4 2 2 4 3 8 6 7 7 9 5 6 3 12 12 6 6 8 4 5 1 contains seven big peaks wrt a tolerance of 0 (i.e., we consider standard peaks).

As shown part Part (B) of Figure 5.138, the second BIG_PEAK constraint holds since the same sequence 4 2 2 4 3 8 6 7 7 9 5 6 3 12 12 6 6 8 4 5 1 contains only four big peaks wrt a tolerance of 1.

Typical

\[
\begin{align*}
N ≥ 1 \\
|\text{VARIABLES}| > 6 \\
\text{range(\text{VARIABLES}.var)} > 1 \\
\text{TOLERANCE} > 1
\end{align*}
\]
**Typical model**

- `nval(VARIABLES.var) > 2`
- `range(VARIABLES.var) > 2`

**Symmetries**

- Items of `VARIABLES` can be reversed.
- One and the same constant can be added to the `var` attribute of all items of `VARIABLES`.

**Arg. properties**

- **Functional dependency:** N determined by `VARIABLES` and `TOLERANCE`.
- **Contractible** wrt. `VARIABLES` when `N = 0` and `TOLERANCE = 0`.

**Usage**

Useful for constraining the number of *big peaks* of a sequence of domain variables, by ignoring too small valleys that artificially create small peaks wrt `TOLERANCE`.

**See also**

- **specialisation:** `PEAK` *(the tolerance is set to 0 and removed)*.

**Keywords**

- **characteristic of a constraint:** automaton, automaton with counters.
- **combinatorial object:** sequence.
- **constraint arguments:** pure functional dependency.
- **modelling:** functional dependency.
Figure 5.138: Illustration of the Example slot: Part (A) a sequence of 21 variables $V_1, V_2, \ldots, V_{21}$ respectively fixed to values 4, 2, 2, 4, 3, 8, 6, 7, 7, 9, 5, 6, 3, 12, 12, 6, 6, 8, 4, 5, 1 and its corresponding 7 peaks ($TOLERANCE = 0$ corresponds to standard peaks) with their respective heights $h_0^1 = 1, h_0^2 = 2, h_0^3 = 3, h_0^4 = 1, h_0^5 = 6, h_0^6 = 2, h_0^7 = 1$ (the left and right hand sides of each peak are coloured in light orange and light red)

Part (B) the same sequence of variables and its 4 big peaks when $TOLERANCE = 1$ with their respective heights $h_1^1 = 2, h_1^2 = 3, h_1^3 = 6, h_1^4 = 2$
Figure 5.139: Automaton for the BIG_PEAK constraint where \( C \), \( S \), \( P \), \( \text{min} \) and \( \Delta \) respectively stand for the number of big peaks already encountered, the altitude at the start of the current potential big peak, the altitude of the current potential big peak, the smallest value that can be assigned to a variable of VARIABLES, the TOLERANCE parameter.
5.54 BIG VALLEY

Origin
Derived from VALLEY.

Constraint
\[ \text{BIG\_VALLEY}(N, \text{VARIABLES}, \text{TOLERANCE}) \]

Arguments
\[
\begin{align*}
N & : \text{dvar} \\
\text{VARIABLES} & : \text{collection(var\text{-}dvar)} \\
\text{TOLERANCE} & : \text{int}
\end{align*}
\]

Restrictions
\[
\begin{align*}
N & \geq 0 \\
2 \cdot N & \leq \max(|\text{VARIABLES}| - 1, 0) \\
\text{TOLERANCE} & \geq 0
\end{align*}
\]

A variable \( V_v \) (\( 1 < k < m \)) is a valley if and only if there exists an \( i \) (\( 1 < i \leq v \)) such that \( V_{i-1} > V_i \) and \( V_i = V_{i+1} = \cdots = V_v \) and \( V_v < V_{v+1} \). Similarly, a variable \( V_p \) (\( 1 < p < m \)) of the sequence \( \text{VARIABLES} = V_1, \ldots, V_m \) is a peak if and only if there exists an \( i \) (\( 1 < i \leq p \)) such that \( V_{i-1} < V_i \) and \( V_i = V_{i+1} = \cdots = V_p \). A valley variable \( V_v \) (\( 1 < v < m \)) is a potential big valley wrt a non-negative integer \( \text{TOLERANCE} \) if and only if:

1. \( V_v \) is a valley,
2. \( \exists i, j \in [1, m] \mid i < v < j, \ V_i \) is a peak (or \( i = 1 \) if there is no peak before position \( p \)), \( V_j \) is a peak (or \( i = m \) if there is no peak after position \( p \)), \( V_i - V_v > \text{TOLERANCE} \), and \( V_j - V_v > \text{TOLERANCE} \).

Let \( i_v \) and \( j_v \) be the largest \( i \) and the smallest \( j \) satisfying condition 2. Now a potential big valley \( V_v \) (\( 1 < v < m \)) is a big valley if and only if the interval \( [i_v, j_v] \) does not contain any potential big valley that is strictly less than \( V_v \). The constraint BIG\_VALLEY holds if and only if \( N \) is the total number of big valleys of the sequence of variables \( \text{VARIABLES} \).

Example
\[
(7, (9, 11, 11, 9, 10, 5, 7, 6, 6, 4, 8, 7, 10, 1, 1, 7, 7, 5, 9, 8, 12), 0) \\
(4, (9, 11, 11, 9, 10, 5, 7, 6, 6, 4, 8, 7, 10, 1, 1, 7, 7, 5, 9, 8, 12), 1)
\]

As shown part Part (A) of Figure 5.140, the first BIG\_VALLEY constraint holds since the sequence \( 9 11 11 9 10 5 7 6 6 4 8 7 10 1 1 7 7 5 9 8 12 \) contains seven big valleys wrt a tolerance of 0 (i.e., we consider standard valleys).

As shown part Part (B) of Figure 5.140, the second BIG\_VALLEY constraint holds since the same sequence \( 9 11 11 9 10 5 7 6 6 4 8 7 10 1 1 7 7 5 9 8 12 \) contains only four big valleys wrt a tolerance of 1.

Typical
\[
\begin{align*}
N & \geq 1 \\
|\text{VARIABLES}| & > 6 \\
\text{range}(\text{VARIABLES}.\text{var}) & > 1 \\
\text{TOLERANCE} & > 1
\end{align*}
\]
**Typical model**

<table>
<thead>
<tr>
<th>nval(VARIABLES.var) &gt; 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>range(VARIABLES.var) &gt; 2</td>
</tr>
</tbody>
</table>

**Symmetries**

- Items of VARIABLES can be reversed.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

**Arg. properties**

- **Functional dependency**: \( N \) determined by VARIABLES and TOLERANCE.
- **Contractible** wrt. VARIABLES when \( N = 0 \) and TOLERANCE = 0.

**Usage**

Useful for constraining the number of *big valleys* of a sequence of domain variables, by ignoring too small peaks that artificially create small valleys wrt TOLERANCE.

**See also**

specialisation: VALLEY (*the tolerance is set to 0 and removed*).

**Keywords**

- **characteristic of a constraint**: automaton, automaton with counters.
- **combinatorial object**: sequence.
- **constraint arguments**: pure functional dependency.
- **modelling**: functional dependency.
Figure 5.140: Illustration of the Example slot: Part (A) a sequence of 21 variables $V_1, V_2, \ldots, V_{21}$ respectively fixed to values $9, 11, 11, 9, 10, 5, 7, 6, 6, 4, 8, 7, 10, 1, 1, 7, 7, 5, 9, 8, 12$ and its corresponding 7 valleys (TOLERANCE $= 0$ corresponds to standard valleys) with their respective depths $d_{01} = 1, d_{02} = 2, d_{03} = 3, d_{04} = 1, d_{05} = 6, d_{06} = 2, d_{07} = 1$ (the left and right hand sides of each valley are coloured in light orange and light red) Part (B) the same sequence of variables and its 4 big valleys when TOLERANCE $= 1$ with their respective depths $d_{11} = 2, d_{12} = 3, d_{13} = 6, d_{14} = 2$
Automaton

Figure 5.141 depicts the automaton associated with the BIG\_VALLEY constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection VARIABLES corresponds a signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i, \text{VAR}_{i+1}\) and \(S_i\):

\[
(\text{VAR}_i < \text{VAR}_{i+1} \Leftrightarrow S_i = 0) \land (\text{VAR}_i = \text{VAR}_{i+1} \Leftrightarrow S_i = 1) \land (\text{VAR}_i > \text{VAR}_{i+1} \Leftrightarrow S_i = 2).
\]

\[
C \leftarrow 0, \\
S \leftarrow 0, \\
V \leftarrow \text{\textit{max}}
\]

\[
N = C + \left( \left( \text{VAR}_{\text{VARIABLES}} - V \right) > \Delta \right)
\]

\[
\{ S \leftarrow \text{VAR}_i \} \\
\{ \text{\textit{max}} \}
\]

\[
\{ V = \text{\textit{max}}, S \leftarrow \text{VAR}_i \} \\
\{ V < \text{\textit{max}} \land \text{VAR}_i - V \leq \Delta \} \\
\{ \text{VAR}_i - V > \Delta, C \leftarrow C + 1, S \leftarrow \text{VAR}_i, V \leftarrow \text{\textit{max}} \}
\]

Figure 5.141: Automaton for the BIG\_VALLEY where \(C, S, V, \text{\textit{max}}\) and \(\Delta\) respectively stand for the number of big valleys already encountered, the altitude at the start of the current potential big valley, the altitude of the current potential big valley, the largest value that can be assigned to a variable of VARIABLES, the TOLERANCE parameter.
5.55 BIN_PACKING

Origin
Derived from CUMULATIVE.

Constraint
BIN_PACKING(CAPACITY, ITEMS)

Arguments
CAPACITY : int
ITEMS : collection(bin-dvar, weight-int)

Restrictions
CAPACITY ≥ 0
required(ITEMS, [bin, weight])
ITEMS.weight ≥ 0
ITEMS.weight ≤ CAPACITY

Purpose
Given several items of the collection ITEMS (each of them having a specific weight), and different bins of a fixed capacity, assign each item to a bin so that the total weight of the items in each bin does not exceed CAPACITY.

Example
The BIN_PACKING constraint holds since the sum of the height of items that are assigned to bins 1 and 3 is respectively equal to 3 and 5. The previous quantities are both less than or equal to the maximum CAPACITY 5. Figure 5.142 shows the solution associated with the example.

![Diagram of bin packing solution](image)

Figure 5.142: Bin-packing solution to the Example slot
### BIN_PACKING

**Typical**

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CAPACITY &gt; maxval(ITEMS.weight)</code></td>
<td></td>
</tr>
<tr>
<td><code>CAPACITY ≤ sum(ITEMS.weight)</code></td>
<td></td>
</tr>
<tr>
<td>`</td>
<td>ITEMS</td>
</tr>
<tr>
<td><code>range(ITEMS.bin) &gt; 1</code></td>
<td></td>
</tr>
<tr>
<td><code>range(ITEMS.weight) &gt; 1</code></td>
<td></td>
</tr>
<tr>
<td><code>ITEMS.bin ≥ 0</code></td>
<td></td>
</tr>
<tr>
<td><code>ITEMS.weight &gt; 0</code></td>
<td></td>
</tr>
</tbody>
</table>

**Symmetries**

- `CAPACITY` can be increased.
- Items of `ITEMS` are permutable.
- `ITEMS.weight` can be decreased to any value ≥ 0.
- All occurrences of two distinct values of `ITEMS.bin` can be swapped; all occurrences of a value of `ITEMS.bin` can be renamed to any unused value.

**Arg. properties**

- Contractible wrt. `ITEMS`.

**Remark**

Note the difference from the *classical* bin-packing problem [286, page 221] where one wants to find solutions that minimise the number of bins. In our case each item may be assigned only to specific bins (i.e., the different values of the bin variable) and the goal is to find a feasible solution. This constraint can be seen as a special case of the CUMULATIVE constraint [1], where all task durations are equal to 1.

In [390] the `CAPACITY` parameter of the BIN_PACKING constraint is replaced by a collection of domain variables representing the load of each bin (i.e., the sum of the weights of the items assigned to a bin). This allows representing problems where a minimum level has to be reached in each bin.

Coffman and al. give in [128] the worst case bounds of different list algorithms for the bin packing problem (i.e., given a positive integer `CAPACITY` and a list `L` of integer sizes `weight_1, weight_2, ..., weight_n` (0 ≤ `weight_i` ≤ `CAPACITY`), what is the smallest integer `m` such that there is a partition `L = L_1 ∪ L_2 ∪ ... ∪ L_m` satisfying `∑_{i ∈ L_j} weight_i ≤ CAPACITY` for all `j ∈ [1, m]`?

**Algorithm**

Initial filtering algorithms are described in [302, 299, 300, 301, 390]. More recently, linear continuous relaxations based on the graph associated with the dynamic programming approach for knapsack by Trick [419], and on the more compact model introduced by Carvalho [110, 111] are presented in [98].

**Systems**

$\text{ARITH}(C_i \leq \text{CAPACITY})$

Figure 5.144: Automaton of the BIN_PACKING constraint
5.56 BIN_PUBLISH_CAPA

**Description**

**Origin**

Derived from BIN_PACKING.

**Constraint**

BIN_PUBLISH_CAPA(BINS, ITEMS)

**Arguments**

BINS : collection(id-int, capa-int)
ITEMS : collection(bin-dvar, weight-int)

**Restrictions**

|BINS| > 0
required(BINS, [id, capa])
distinct(BINS, id)
BINS.id ≥ 1
BINS.id ≤ |BINS|
BINS.capa ≥ 0
required(ITEMS, [bin, weight])
in_attr(ITEMS, bin, BINS.id)
ITEMS.weight ≥ 0

**Purpose**

Given several items of the collection ITEMS (each of them having a specific weight), and different bins described the items of collection BINS (each of them having a specific capacity capa), assign each item to a bin so that the total weight of the items in each bin does not exceed the capacity of the bin.

**Example**

\[
\left(\begin{array}{c}
id - 1 \quad \text{capa} - 4, \\
id - 2 \quad \text{capa} - 3, \\
id - 3 \quad \text{capa} - 5, \\
id - 4 \quad \text{capa} - 3, \\
id - 5 \quad \text{capa} - 3 \\
\text{bin} - 3 \quad \text{weight} - 4, \\
\text{bin} - 1 \quad \text{weight} - 3, \\
\text{bin} - 3 \quad \text{weight} - 1
\end{array}\right)
\]

The BIN_PUBLISH_CAPA constraint holds since the sum of the height of items that are assigned to bins 1 and 3 is respectively equal to 3 and 5. The previous quantities are respectively less than or equal to the maximum capacities 4 and 5 of bins 1 and 3.

**Typical**

|BINS| > 1
range(BINS.capa) > 1
BINS.capa > maxval(ITEMS.weight)
BINS.capa ≤ sum(ITEMS.weight)
|ITEMS| > 1
range(ITEMS.bin) > 1
range(ITEMS.weight) > 1
ITEMS.weight > 0
Figure 5.145: Bin-packing solution to the Example slot

Symmetries
- Items of BINS are permutable.
- Items of ITEMS are permutable.
- BINS.capa can be increased.
- ITEMS.weight can be decreased to any value $\geq 0$.
- All occurrences of two distinct values in BINS.id or ITEMS.bin can be swapped; all occurrences of a value in BINS.id or ITEMS.bin can be renamed to any unused value.

Arg. properties
Contractible wrt. ITEMS.

Remark
In MiniZinc (http://www.minizinc.org/) there is also a constraint called BIN_PACKING_LOAD which, for each bin has a domain variable that is equal to the sum of the weights assigned to the corresponding bin.

Systems
PACK in Choco, BINPACKING in Gecode, BIN_PACKING_CAPA in MiniZinc.

modelling exercises: assignment to the same set of values.
5.57 BINARY_TREE

**Origin**
Derived from TREE.

**Constraint**
BINARY_TREE(NTREES, NODES)

**Arguments**
- NTREES : dvar
- NODES : collection(index=int, succ=dvar)

**Restrictions**
- NTREES ≥ 0
- NTREES ≤ |NODES|
- required(NODES, [index, succ])
- NODES.index ≥ 1
- NODES.index ≤ |NODES|
- distinct(NODES, index)
- NODES.succ ≥ 1
- NODES.succ ≤ |NODES|

**Purpose**
Cover the digraph $G$ described by the NODES collection with NTREES binary trees in such a way that each vertex of $G$ belongs to exactly one binary tree (i.e., each vertex of $G$ has at most two children). The edges of the binary trees are directed from their leaves to their respective roots.
The first `BINARY_TREE` constraint holds since its second argument corresponds to the 2 (i.e., the first argument of the first `BINARY_TREE` constraint) binary trees depicted by Figure 5.146.

Figure 5.146: The two binary trees corresponding to the first example of the Example slot; each vertex contains the information `index|succ` where `succ` is the index of its father in the tree (by convention the father of the root is the root itself).

All solutions Figure 5.147 gives all solutions to the following non ground instance of the `BINARY_TREE` constraint: \( \text{NTR} \in \{1, 4\}, S_1 \in [1, 2], S_2 \in [1, 3], S_3 \in [3, 4], S_4 \in [3, 4], S_5 \in [2, 3], \text{BINARY_TREE}(\text{NTR}, \langle 1 \ S_1, 2 \ S_2, 3 \ S_3, 4 \ S_4, 5 \ S_5 \rangle) \).
Figure 5.147: All solutions corresponding to the non ground example of the \texttt{BINARY TREE} constraint of the \textbf{All solutions} slot, where all vertices of a same tree are coloured by the same colour; in the left-hand side the \texttt{index} attributes are displayed as indices of the \texttt{succ} attribute, while in the right-hand side they are directly displayed within each node.

**Typical**

\begin{align*}
\text{NTREES} &> 0 \\
\text{NTREES} &< |\text{NODES}| \\
|\text{NODES}| &> 2
\end{align*}

**Symmetry**

Items of \texttt{NODES} are \textbf{permutable}.

**Arg. properties**

\textbf{Functional dependency:} \texttt{NTREES} determined by \texttt{NODES}.

**Reformulation**

The \texttt{BINARY TREE} constraint can be expressed in term of (1) a set of $|\text{NODES}|^2$ reified constraints for avoiding circuit between more than one node and of (2) $|\text{NODES}|$ reified constraints and of one sum constraint for counting the trees and of (3) a set of $|\text{NODES}|^2$ reified constraints and of $|\text{NODES}|$ inequalities constraints for enforcing the fact that each vertex has at most two children.

1. For each vertex $\text{NODES}[i]$ ($i \in [1,|\text{NODES}|]$) of the \texttt{NODES} collection we create a variable $R_i$ that takes its value within interval $[1,|\text{NODES}|]$. This variable represents the \texttt{rank} of vertex $\text{NODES}[i]$ within a solution. It is used to prevent the creation of circuit involving more than one vertex as explained now. For each pair of vertices $\text{NODES}[i], \text{NODES}[j]$ ($i,j \in [1,|\text{NODES}|]$) of the \texttt{NODES} collection we create a reified constraint of the form $\text{NODES}[i].\text{succ} = \text{NODES}[j].\text{index} \land i \neq j \Rightarrow R_i < R_j$. The purpose of this constraint is to express the fact that, if there is an arc from vertex $\text{NODES}[i]$ to another vertex $\text{NODES}[j]$, then $R_i$ should be strictly less than $R_j$.

2. For each vertex $\text{NODES}[i]$ ($i \in [1,|\text{NODES}|]$) of the \texttt{NODES} collection we create a 0-1 variable $B_i$ and state the following reified constraint $\text{NODES}[i].\text{succ} =$
NODES[i].index $\iff$ $B_i$ in order to force variable $B_i$ to be set to value 1 if and only if there is a loop on vertex NODES[i]. Finally we create a constraint $\text{NTREES} = B_1 + B_2 + \cdots + B_{\mid\text{NODES}}$ for stating the fact that the number of trees is equal to the number of loops of the graph.

3. For each pair of vertices NODES[i], NODES[j] ($i, j \in [1, \mid\text{NODES}])$ of the NODES collection we create a 0-1 variable $B_{ij}$ and state the following reified constraint 

$$\text{NODES}[i].\text{succ} = \text{NODES}[j].\text{index} \land i \neq j \iff B_{ij}.$$ 

Variable $B_{ij}$ is set to value 1 if and only if there is an arc from NODES[i] to NODES[j]. Then for each vertex NODES[j] ($j \in [1, \mid\text{NODES}])$ we create a constraint of the form $B_{1j} + B_{2j} + \cdots + B_{\mid\text{NODES}j} \leq 2$.

  • $\text{MAX_NSCC} \leq 1$
  • $\text{NCC} = \text{NTREES}$
  • $\text{MAX_ID} \leq 2$
Graph class  ONE_SUCC

Graph model  

We use the same graph constraint as for the $\text{TREE}$ constraint, except that we add the graph property $\text{MAX_ID} \leq 2$, which constrains the maximum in-degree of the final graph to not exceed 2. $\text{MAX_ID}$ does not consider loops: This is why we do not have any problem with the root of each tree.

Parts (A) and (B) of Figure 5.148 respectively show the initial and final graph associated with the first example of the Example slot. Since we use the $\text{NCC}$ graph property, we display the two connected components of the final graph. Each of them corresponds to a binary tree. Since we use the $\text{MAX_IN_DEGREE}$ graph property, we also show with a double circle a vertex that has a maximum number of predecessors.

The $\text{BINARY_TREE}$ constraint holds since all strongly connected components of the final graph have no more than one vertex, since $\text{NTREES} = \text{NCC} = 2$ and since $\text{MAX_ID} = 2$. 
Figure 5.148: Initial and final graph of the BINARY_TREE constraint
BINARY_TREE 795
5.58 BIPARTITE

<table>
<thead>
<tr>
<th>DESCRIPTION</th>
<th>LINKS</th>
<th>GRAPH</th>
</tr>
</thead>
</table>

**Origin**  
[151]

**Constraint**  
BIPARTITE(NODES)

**Argument**  
NODES : collection(index=int, succ=svar)

**Restrictions**  

| required(NODES,[index, succ])  
| NODES.index ≥ 1  
| NODES.index ≤ |NODES|  
| distinct(NODES, index)  
| NODES.succ ≥ 1  
| NODES.succ ≤ |NODES|

**Purpose**  
Consider a digraph $G$ described by the NODES collection. Select a subset of arcs of $G$ so that the corresponding graph is symmetric (i.e., if there is an arc from $i$ to $j$, there is also an arc from $j$ to $i$) and bipartite (i.e., there is no cycle involving an odd number of vertices).

**Example**  

\[
\begin{align*}
\text{index} - 1 & \quad \text{succ} = \{2, 3\}, \\
\text{index} - 2 & \quad \text{succ} = \{1, 4\}, \\
\text{index} - 3 & \quad \text{succ} = \{1, 4, 5\}, \\
\text{index} - 4 & \quad \text{succ} = \{2, 3, 6\}, \\
\text{index} - 5 & \quad \text{succ} = \{3, 6\}, \\
\text{index} - 6 & \quad \text{succ} = \{4, 5\}
\end{align*}
\]

The BIPARTITE constraint holds since the NODES collection depicts a symmetric graph with no cycle involving an odd number of vertices. The corresponding graph is depicted by Figure 5.149.

![Graph](image)

Figure 5.149: Two ways of looking at the bipartite graph given in the Example slot

**Typical**  
$|\text{NODES}| > 2$

**Symmetry**  
Items of NODES are permutable.
### Algorithm

The sketch of a filtering algorithm for the BIPARTITE constraint is given in [151, page 91]. Beside enforcing the fact that the graph is symmetric, it checks that the subset of mandatory vertices and arcs is bipartite and removes all potential arcs that would make the previous graph non-bipartite.

Part (A) of Figure 5.150 shows the initial graph from which we start. It is derived from the set associated with each vertex. Each set describes the potential values of the `succ` attribute of a given vertex. Part (B) of Figure 5.150 gives the final graph associated with the `Example` slot.

Figure 5.150: Initial and final graph of the BIPARTITE set constraint
5.59 CALENDAR

Origin [28]

Constraint 

Type

UNAVAILABILITIES : collection(low-int, up-int)

Arguments

INSTANTS : collection(machine-dvar, virtual-dvar, ireal-dvar, flagend-int)

MACHINES : collection(id-int, cal - UNAVAILABILITIES)

Restrictions

required(UNAVAILABILITIES, [low, up])
UNAVAILABILITIES.low ≤ UNAVAILABILITIES.up
required(INSTANTS, [machine, virtual, ireal, flagend])

in_attr(INSTANTS, machine, MACHINES, id)
INSTANTS.flagend ≥ 0
INSTANTS.flagend ≤ 1
|MACHINES| > 0
required(MACHINES, [id, cal])
distinct(MACHINES, id)

Purpose

Makes the link between an universal calendar and resource dependent calendars. Given a collection of machines MACHINES where each machine is defined by its identifier and its unavailability periods the CALENDAR constraint maps items of real and virtual dates depending on the machine assignment as well as of the fact that we consider start (flagend = 0) or end (flagend = 1) times. Virtual dates on a given machine m do not consider the unavailability periods on m, while real dates consider all time points.

Example

\[
\begin{align*}
\text{machine - 1} & \quad \text{virtual - 2} & \quad \text{ireal - 3} & \quad \text{flagend - 0}, \\
\text{machine - 1} & \quad \text{virtual - 5} & \quad \text{ireal - 6} & \quad \text{flagend - 1}, \\
\text{machine - 2} & \quad \text{virtual - 4} & \quad \text{ireal - 5} & \quad \text{flagend - 0}, \\
\text{machine - 2} & \quad \text{virtual - 6} & \quad \text{ireal - 9} & \quad \text{flagend - 1}, \\
\text{machine - 3} & \quad \text{virtual - 2} & \quad \text{ireal - 2} & \quad \text{flagend - 0}, \\
\text{machine - 3} & \quad \text{virtual - 5} & \quad \text{ireal - 5} & \quad \text{flagend - 1}, \\
\text{machine - 4} & \quad \text{virtual - 2} & \quad \text{ireal - 2} & \quad \text{flagend - 0}, \\
\text{machine - 4} & \quad \text{virtual - 7} & \quad \text{ireal - 9} & \quad \text{flagend - 1}, \\
\text{id - 1} & \quad \text{cal - } & \quad \text{[low - 2 up - 2, low - 6 up - 7]}, \\
\text{id - 2} & \quad \text{cal - } & \quad \text{[low - 2 up - 2, low - 6 up - 7]}, \\
\text{id - 3} & \quad \text{cal - } & \quad [], \\
\text{id - 4} & \quad \text{cal - } & \quad \text{[low - 3 up - 4]},
\end{align*}
\]
Figure 5.151 illustrates the example. It present four machines with their respective unavailability periods (in grey) as well as four tasks (in blue and pink). Each item of the INSTANTS collection corresponds to the start or to the end of one of the previous four tasks. The CALENDAR constraint holds since:

- The real date 3 (INSTANTS[1].ireal = 3) associated with the start (INSTANTS[1].flagend = 0) of task (a) in the universal time corresponds to the virtual date 2 (INSTANTS[1].virtual = 2) on machine 1 (INSTANTS[1].machine = 1).
- The real date 6 (INSTANTS[2].ireal = 6) associated with the end (INSTANTS[2].flagend = 1) of task (a) in the universal time corresponds to the virtual date 5 (INSTANTS[2].virtual = 5) on machine 1 (INSTANTS[2].machine = 1).
- The real date 5 (INSTANTS[3].ireal = 5) associated with the start (INSTANTS[3].flagend = 0) of task (b) in the universal time corresponds to the virtual date 4 (INSTANTS[3].virtual = 4) on machine 2 (INSTANTS[3].machine = 2).
- The real date 9 (INSTANTS[4].ireal = 9) associated with the end (INSTANTS[4].flagend = 1) of task (b) in the universal time corresponds to the virtual date 6 (INSTANTS[4].virtual = 6) on machine 2 (INSTANTS[4].machine = 2).
- The real date 2 (INSTANTS[5].ireal = 2) associated with the start (INSTANTS[5].flagend = 0) of task (c) in the universal time corresponds to the virtual date 2 (INSTANTS[5].virtual = 2) on machine 3 (INSTANTS[5].machine = 3).
- The real date 5 (INSTANTS[6].ireal = 5) associated with the end (INSTANTS[6].flagend = 1) of task (c) in the universal time corresponds to the virtual date 5 (INSTANTS[6].virtual = 5) on machine 3 (INSTANTS[6].machine = 3).
- The real date 2 (INSTANTS[7].ireal = 2) associated with the start (INSTANTS[7].flagend = 0) of task (d) in the universal time corresponds to the virtual date 2 (INSTANTS[7].virtual = 2) on machine 4 (INSTANTS[7].machine = 4).
- The real date 9 (INSTANTS[8].ireal = 9) associated with the end (INSTANTS[8].flagend = 1) of task (d) in the universal time corresponds to the virtual date 7 (INSTANTS[8].virtual = 7) on machine 4 (INSTANTS[8].machine = 4).

Typical
|INSTANTS| > 1
|MACHINES| > 1

Symmetries
- Items of INSTANTS are permutable.
- Items of MACHINES are permutable.

Arg. properties
Contractible wrt. INSTANTS.
Figure 5.151: Four machines with their unavailability periods as well as four tasks assigned to these machines (virtual dates mentioned in the Example slot use a bold font)

Usage

The CALENDAR constraint is used as a channelling constraint in resource scheduling problems where resources have unavailability periods that can preempt the execution of a task. In this context two time coordinate systems are used:

- A first coordinate system, so called the virtual coordinate system, ignores all unavailability periods on the different resources. All resource constraints are stated within this virtual coordinate system.

- A second coordinate system, so called the real coordinate system, corresponds to the real time. All temporal constraints (e.g., precedence constraints) are stated within this real coordinate system.

In this context, each task has a virtual origin, a virtual duration, a virtual end, a real origin, a real duration, a real end and the CALENDAR constraint links together the virtual origin and the real origin as well as the virtual end and the real end. The virtual duration (i.e., the real duration plus the sum of the unavailability periods crossed by the task) is linked to the virtual end and the virtual origin through an equality constraint on the difference between the virtual end and the virtual origin. The real duration is linked in a similar way to the real end and the real origin. The keyword scheduling with machine choice, calendars and preemption provides a concrete example of resource scheduling problem using the CALENDAR constraint.

Reformulation

The CALENDAR constraint can be reformulated into two generalised CASE constraints (i.e., two CASE constraints augmented with linear constraints). Part (A) (respectively Part (B)) of Figure 5.152 provides the directed acyclic graph that allows mapping the virtual start and real start (respectively the virtual end and real end) of a task. This directed acyclic graph can be computed directly from the arguments of the CALENDAR constraint:

1. We create an initial root node labelled by $m$ and we partition the set of machines into classes of consecutive machines that all share exactly the same unavailability periods. For each such class we create an arc from the root node to a new node $v_S$ labelled by the corresponding interval of consecutive machines identifiers. In Part (A) this corresponds to node $m$ and its three outgoing arcs respectively labelled by intervals $[1, 2]$, $[3, 3]$ and $[4, 4]$. 
2. For each class of consecutive machines found previously, we label in increasing order each timepoint that is not part of an unavailability period. We create an arc from the corresponding node vs for each maximum interval of available timepoints to a new node labelled by rs. In Part (A) this translate to:

- For the class corresponding to machines 1 and 2 we create three outgoing arcs labelled by the time intervals [1, 1], [2, 4] and [5, 6].
- For the class corresponding to machine 3 we create the outgoing arc labelled by time interval [1, 9].
- For the class corresponding to machine 4 we create the two outgoing arcs labelled by the time intervals [1, 2] and [3, 7].

3. For each class of consecutive machines and for each maximum interval [i, j] of available timepoints previously computed, we find out the number of unavailable timepoints bi on the same class of machines that are located before the virtual date i. We create an outgoing arc from the corresponding node rs to a new node labelled by true (there is a single true node for the full directed acyclic graph). This arc is labelled by the interval [i + bi, j + bi] and by the linear constraint rs = vs + bi. In Part (A) this translate to:

- For the class corresponding to machines 1 and 2 and for each rs node associated with the time intervals [1, 1], [2, 4] and [5, 6] we respectively create an outgoing arc labelled by intervals [1, 1], [3, 5] and [8, 9]. To each of these arcs we also respectively associate the linear constraints rs = vs + 0 (+0 since on machines 1 and 2 there is no unavailability period before the virtual date 1), rs = vs + 1 (+1 since on machines 1 and 2 there is a single unavailable timepoint before the virtual date 2) and rs = vs + 3 (+3 since on machines 1 and 2 there is three unavailable timepoints before the virtual date 5).

- For the class corresponding to machine 3 and for the rs node associated with the time interval [1, 9] we create the outgoing arc labelled by time interval [1, 9] and by rs = vs + 0 (i.e., since there is no unavailability period at all on machine 3).

- For the class corresponding to machine 4 and for each rs node associated with the time intervals [1, 2] and [3, 7] we respectively create an outgoing arc labelled by [1, 2] and [5, 9]. To each of these arcs we also respectively associate the linear constraints rs = vs + 0 (+0 since on machine 4 there is no unavailability period before the virtual date 1) and rs = vs + 2 (+2 since on machine 4 there is two unavailable timepoints before the virtual date 3).

The CALENDAR constraint can also be reformulated into a conjunction of reified constraints. This is done by generating, for each pair of items (I, M) of the INSTANTS and MACHINES collections, a set of reified constraints expressing:

- The link between the real and the virtual dates under the hypothesis that the machine attribute of item I is assigned to the value of the id attribute of item M. More precisely, we generate one reified constraint for each available time interval on machine id.

- The fact that a real date should not be located within an unavailability period of its corresponding machine.

Operationally, this leads to the following cases:
1. When machine id has no unavailability at all we state an equality constraint between
the real and virtual dates.
2. When the real date is located before the first unavailability period we also state an
equality constraint between the real and virtual dates.
3. When the real date is located between two consecutive unavailability periods we
state:
   • An equality constraint between the real date and the virtual date plus the sum
     of all unavailabilities located before the real date.
   • An implication between the fact that the real date belongs to the first unavail-
     ability period (among the two consecutive unavailability periods) and the fact
     that the real date is not assigned to the machine that contains the unavailability
     period.
4. When the real date is located after the last unavailability period we state:
   • An equality constraint between the real date and the virtual date plus the sum
     of all unavailabilities.
   • An implication between the fact that the real date belongs to the last unavail-
     ability period and the fact that the real date is not assigned to the machine that
     contains the unavailability period.

As an example consider again consider the instance given in the Example slot. For the
start of task a (i.e., the first item ⟨machine − 1 virtual − 2 ireal − 2 flagend − 0⟩
of collection INSTANTS), we generate the following reified constraints, where equivalences
of the form true ⇔ true are shown in bold:

- (if task a is assigned on machine 1)
  * before [2, 2]:       1 = 1 ∧ 3 < 2 ⇔ 1 = 1 ∧ 3 = 2
  * between [2, 2] and [6, 7]: 1 = 1 ∧ 3 > 2 ∧ 3 < 6 ⇔ 1 = 1 ∧ 3 = 2 + 1
  * after [6, 7]:        1 = 1 ∧ 3 > 7 ⇔ 1 = 1 ∧ 3 = 2 + 3
  * do not cross [2, 2], [6, 7]: 3 ∈ [2, 2] ⇒ 1 ≠ 1, 3 ∈ [6, 7] ⇔ 1 ≠ 1

- (if task a is assigned on machine 2)
  * before [2, 2]:       1 = 2 ∧ 3 < 2 ⇔ 1 = 2 ∧ 3 = 2
  * between [2, 2] and [6, 7]: 1 = 2 ∧ 3 > 2 ∧ 3 < 6 ⇔ 1 = 2 ∧ 3 = 2 + 1
  * after [6, 7]:        1 = 2 ∧ 3 > 7 ⇔ 1 = 2 ∧ 3 = 2 + 3
  * do not cross [2, 2], [6, 7]: 3 ∈ [2, 2] ⇒ 1 ≠ 2, 3 ∈ [6, 7] ⇔ 1 ≠ 2

- (if task a is assigned on machine 3)
  * no unavailability:        1 = 3 ⇔ 1 = 3 ∧ 3 = 2

- (if task a is assigned on machine 4)
  * before [3, 4]:          1 = 4 ∧ 3 < 3 ⇔ 1 = 4 ∧ 3 = 2
  * after [3, 4]:          1 = 4 ∧ 3 > 4 ⇔ 1 = 4 ∧ 3 = 2 + 2
  * do not cross [3, 4]:    3 ∈ [3, 4] ⇒ 1 ≠ 4
Figure 5.152: The two generalised CASE constraints for respectively mapping (A) the virtual start and real start of a task corresponding to the Example slot as well as (B) the virtual end and real end; the directed acyclic graphs were generated under the hypothesis that the virtual and real dates are located in [1,9].
For the end of task a (i.e., the second item \(\text{machine} - 1 \, \text{virtual} - 5 \, \text{ireal} - 6 \, \text{flagend} - 1\)) of collection \text{INSTANTS}, we generate the following reified constraints:

- **(if task a is assigned on machine 1)**
  - before [2, 2]: \(1 = 1 \land 6 < 3 \iff 1 = 1 \land 6 = 5\)
  - between [2, 2] and [6, 7]: \(1 = 1 \land 6 > 3 \land 6 < 7 \iff 1 = 1 \land 6 = 5 + 1\)
  - after [6, 7]: \(1 = 1 \land 6 < 8 \iff 1 = 1 \land 6 = 5 + 3\)
  - do not cross [2, 2], [6, 7]: \(6 \in [3, 3] \Rightarrow 1 \neq 1, 6 \in [7, 8] \Rightarrow 1 \neq 1\)

- **(if task a is assigned on machine 2)**
  - before [2, 2]: \(1 = 2 \land 6 < 3 \iff 1 = 2 \land 6 = 5\)
  - between [2, 2] and [6, 7]: \(1 = 2 \land 6 > 3 \land 6 < 7 \iff 1 = 2 \land 6 = 5 + 1\)
  - after [6, 7]: \(1 = 2 \land 6 < 8 \iff 1 = 2 \land 6 = 5 + 3\)
  - do not cross [2, 2], [6, 7]: \(6 \in [3, 3] \Rightarrow 1 \neq 2, 6 \in [7, 8] \Rightarrow 1 \neq 2\)

- **(if task a is assigned on machine 3)**
  - no unavailability: \(1 = 3 \iff 1 = 3 \land 6 = 5\)

- **(if task a is assigned on machine 4)**
  - before [3, 4]: \(1 = 4 \land 6 < 4 \iff 1 = 4 \land 6 = 5\)
  - after [3, 4]: \(1 = 4 \land 6 > 5 \iff 1 = 4 \land 6 = 5 + 2\)
  - do not cross [3, 4]: \(6 \in [4, 5] \Rightarrow 1 \neq 4\)

For the start of task b (i.e., the third item \(\text{machine} - 2 \, \text{virtual} - 4 \, \text{ireal} - 5 \, \text{flagend} - 0\)) of collection \text{INSTANTS}, we generate the following reified constraints:

- **(if task b is assigned on machine 1)**
  - before [2, 2]: \(2 = 1 \land 5 < 2 \iff 2 = 1 \land 5 = 4\)
  - between [2, 2] and [6, 7]: \(2 = 1 \land 5 > 2 \land 5 < 6 \iff 2 = 1 \land 5 = 4 + 1\)
  - after [6, 7]: \(2 = 1 \land 5 > 7 \iff 2 = 1 \land 5 = 4 + 3\)
  - do not cross [2, 2], [6, 7]: \(5 \in [2, 2] \Rightarrow 2 \neq 1, 5 \in [6, 7] \Rightarrow 2 \neq 1\)

- **(if task b is assigned on machine 2)**
  - before [2, 2]: \(2 = 2 \land 5 < 2 \iff 2 = 2 \land 5 = 4\)
  - between [2, 2] and [6, 7]: \(2 = 2 \land 5 > 2 \land 5 < 6 \iff 2 = 2 \land 5 = 4 + 1\)
  - after [6, 7]: \(2 = 2 \land 5 > 7 \iff 2 = 2 \land 5 = 4 + 3\)
  - do not cross [2, 2], [6, 7]: \(5 \in [2, 2] \Rightarrow 2 \neq 2, 5 \in [6, 7] \Rightarrow 2 \neq 2\)

- **(if task b is assigned on machine 3)**
  - no unavailability: \(2 = 3 \iff 2 = 3 \land 5 = 4\)

- **(if task b is assigned on machine 4)**
  - before [3, 4]: \(2 = 4 \land 5 < 3 \iff 2 = 4 \land 5 = 4\)
  - after [3, 4]: \(2 = 4 \land 5 > 4 \iff 2 = 4 \land 5 = 4 + 2\)
  - do not cross [3, 4]: \(5 \in [3, 4] \Rightarrow 2 \neq 4\)
For the end of task $b$ (i.e., the fourth item \(\text{machine} - 2\ \text{virtual} - 6\ \text{ireal} - 9\ \text{flagend} - 1\)) of collection \text{INSTANTS}, we generate the following reified constraints:

- (if task $b$ is assigned on machine 1)
  * before $[2, 2]$:
    \[2 = 1 \land 9 < 3 \leftrightarrow 2 = 1 \land 9 = 6\]
  * between $[2, 2]$ and $[6, 7]$:
    \[2 = 1 \land 9 > 3 \land 9 < 7 \leftrightarrow 2 = 1 \land 9 = 6 + 1\]
  * after $[6, 7]$:
    \[2 = 1 \land 9 > 8 \leftrightarrow 2 = 1 \land 9 = 6 + 3\]
  * do not cross $[2, 2], [6, 7]$:
    \[9 \in [3, 3] \Rightarrow 2 \neq 1, 9 \in [7, 8] \Rightarrow 2 \neq 1\]

- (if task $b$ is assigned on machine 2)
  * before $[2, 2]$:
    \[2 = 2 \land 9 < 3 \leftrightarrow 2 = 2 \land 9 = 6\]
  * between $[2, 2]$ and $[6, 7]$:
    \[2 = 2 \land 9 > 3 \land 9 < 7 \leftrightarrow 2 = 2 \land 9 = 6 + 1\]
  * after $[6, 7]$:
    \[2 = 2 \land 9 > 8 \leftrightarrow 2 = 2 \land 9 = 6 + 3\]
  * do not cross $[2, 2], [6, 7]$:
    \[9 \in [3, 3] \Rightarrow 2 \neq 2, 9 \in [7, 8] \Rightarrow 2 \neq 2\]

- (if task $b$ is assigned on machine 3)
  * no unavailability:
    \[2 = 3 \leftrightarrow 2 = 3 \land 9 = 6\]

- (if task $b$ is assigned on machine 4)
  * before $[3, 4]$:
    \[2 = 4 \land 9 < 4 \leftrightarrow 2 = 4 \land 9 = 6\]
  * after $[3, 4]$:
    \[2 = 4 \land 9 > 5 \leftrightarrow 2 = 4 \land 9 = 6 + 2\]
  * do not cross $[3, 4]$:
    \[9 \in [4, 5] \Rightarrow 2 \neq 4\]

For the start of task $c$ (i.e., the fifth item \(\text{machine} - 3\ \text{virtual} - 2\ \text{ireal} - 2\ \text{flagend} - 0\)) of collection \text{INSTANTS}, we generate the following reified constraints:

- (if task $c$ is assigned on machine 1)
  * before $[2, 2]$:
    \[3 = 1 \land 2 < 2 \leftrightarrow 3 = 1 \land 2 = 2\]
  * between $[2, 2]$ and $[6, 7]$:
    \[3 = 1 \land 2 > 2 \land 2 < 6 \leftrightarrow 3 = 1 \land 2 = 2 + 1\]
  * after $[6, 7]$:
    \[3 = 1 \land 2 > 7 \leftrightarrow 3 = 1 \land 2 = 2 + 3\]
  * do not cross $[2, 2], [6, 7]$:
    \[2 \in [2, 2] \Rightarrow 3 \neq 1, 2 \in [6, 7] \Rightarrow 3 \neq 1\]

- (if task $c$ is assigned on machine 2)
  * before $[2, 2]$:
    \[3 = 2 \land 2 < 2 \leftrightarrow 3 = 2 \land 2 = 2\]
  * between $[2, 2]$ and $[6, 7]$:
    \[3 = 2 \land 2 > 2 \land 2 < 6 \leftrightarrow 3 = 2 \land 2 = 2 + 1\]
  * after $[6, 7]$:
    \[3 = 2 \land 2 > 7 \leftrightarrow 3 = 2 \land 2 = 2 + 3\]
  * do not cross $[2, 2], [6, 7]$:
    \[2 \in [2, 2] \Rightarrow 3 \neq 2, 2 \in [6, 7] \Rightarrow 3 \neq 2\]

- (if task $c$ is assigned on machine 3)
  * no unavailability:
    \[3 = 3 \leftrightarrow 3 = 3 \land 2 = 2\]

- (if task $c$ is assigned on machine 4)
  * before $[3, 4]$:
    \[3 = 4 \land 2 < 3 \leftrightarrow 3 = 4 \land 2 = 2\]
  * after $[3, 4]$:
    \[3 = 4 \land 2 > 4 \leftrightarrow 3 = 4 \land 2 = 2 + 2\]
  * do not cross $[3, 4]$:
    \[2 \in [3, 4] \Rightarrow 3 \neq 4\]
For the end of task c (i.e., the sixth item \{\text{machine} \rightarrow \text{virtual} \rightarrow \text{ireal} \rightarrow \text{flagend} \rightarrow 1\}) of collection INSTANTS, we generate the following reified constraints:

- (if task c is assigned on machine 1)
  * before [2, 2]: \(3 = 1 \land 5 < 3 \Leftrightarrow 3 = 1 \land 5 = 5\)
  * between [2, 2] and [6, 7]: \(3 = 1 \land 5 > 3 \land 5 < 7 \Leftrightarrow 3 = 1 \land 5 = 5 + 1\)
  * after [6, 7]: \(3 = 1 \land 5 > 8 \Leftrightarrow 3 = 1 \land 5 = 5 + 3\)
  * do not cross [2, 2], [6, 7]: \(5 \in [3..3] \Rightarrow 3 \neq 1, 5 \in [7..8] \Rightarrow 3 \neq 1\)

- (if task c is assigned on machine 2)
  * before [2, 2]: \(3 = 2 \land 5 < 3 \Leftrightarrow 3 = 2 \land 5 = 5\)
  * between [2, 2] and [6, 7]: \(3 = 2 \land 5 > 3 \land 5 < 7 \Leftrightarrow 3 = 2 \land 5 = 5 + 1\)
  * after [6, 7]: \(3 = 2 \land 5 > 8 \Leftrightarrow 3 = 2 \land 5 = 5 + 3\)
  * do not cross [2, 2], [6, 7]: \(5 \in [3..3] \Rightarrow 3 \neq 2, 5 \in [7..8] \Rightarrow 3 \neq 2\)

- (if task c is assigned on machine 3)
  * no unavailability: \(3 = 3 \Leftrightarrow 3 = 3 \land 5 = 5\)

- (if task c is assigned on machine 4)
  * before [3, 4]: \(3 = 4 \land 5 < 4 \Leftrightarrow 3 = 4 \land 5 = 5\)
  * after [3, 4]: \(3 = 4 \land 5 > 5 \Leftrightarrow 3 = 4 \land 5 = 5 + 2\)
  * do not cross [3, 4]: \(5 \in [4..5] \Rightarrow 3 \neq 4\)

For the start of task d (i.e., the seventh item \{\text{machine} \rightarrow \text{virtual} \rightarrow \text{ireal} \rightarrow \text{flagend} \rightarrow 0\}) of collection INSTANTS, we generate the following reified constraints:

- (if task d is assigned on machine 1)
  * before [2, 2]: \(4 = 1 \land 2 < 2 \Leftrightarrow 4 = 1 \land 2 = 2\)
  * between [2, 2] and [6, 7]: \(4 = 1 \land 2 > 2 \land 2 < 6 \Leftrightarrow 4 = 1 \land 2 = 2 + 1\)
  * after [6, 7]: \(4 = 1 \land 2 > 7 \Leftrightarrow 4 = 1 \land 2 = 2 + 3\)
  * do not cross [2, 2], [6, 7]: \(2 \in [2, 2] \Rightarrow 4 \neq 1, 2 \in [6, 7] \Rightarrow 4 \neq 1\)

- (if task d is assigned on machine 2)
  * before [2, 2]: \(4 = 2 \land 2 < 2 \Leftrightarrow 4 = 2 \land 2 = 2\)
  * between [2, 2] and [6, 7]: \(4 = 2 \land 2 > 2 \land 2 < 6 \Leftrightarrow 4 = 2 \land 2 = 2 + 1\)
  * after [6, 7]: \(4 = 2 \land 2 > 7 \Leftrightarrow 4 = 2 \land 2 = 2 + 3\)
  * do not cross [2, 2], [6, 7]: \(2 \in [2, 2] \Rightarrow 4 \neq 2, 2 \in [6, 7] \Rightarrow 4 \neq 2\)

- (if task d is assigned on machine 3)
  * no unavailability: \(4 = 3 \Leftrightarrow 4 = 3 \land 2 = 2\)

- (if task d is assigned on machine 4)
  * before [3, 4]: \(4 = 4 \land 2 < 3 \Leftrightarrow 4 = 4 \land 2 = 2\)
  * after [3, 4]: \(4 = 4 \land 2 > 4 \Leftrightarrow 4 = 4 \land 2 = 2 + 2\)
  * do not cross [3, 4]: \(2 \in [3, 4] \Rightarrow 4 \neq 4\)
For the end of task $d$ (i.e., the eighth item \(\text{machine} - 4 \ \text{virtual} - 7 \ \text{ireal} - 9 \ \text{flagend} - 1\)) of collection INSTANTS, we generate the following reified constraints:

- **(if task $d$ is assigned on machine 1)**
  - before \([2, 2]\):
    \[4 = 1 \land 9 < 3 \iff 4 = 1 \land 9 = 7\]
  - between \([2, 2]\) and \([6, 7]\):
    \[4 = 1 \land 9 > 3 \land 9 < 7 \iff 4 = 1 \land 9 = 7 + 1\]
  - after \([6, 7]\):
    \[4 = 1 \land 9 > 8 \iff 4 = 1 \land 9 = 7 + 3\]
  - do not cross \([2, 2], [6, 7]\):
    \[9 \in [3, 3] \Rightarrow 4 \neq 1, 9 \in [7, 8] \Rightarrow 4 \neq 1\]

- **(if task $d$ is assigned on machine 2)**
  - before \([2, 2]\):
    \[4 = 2 \land 9 < 3 \iff 4 = 2 \land 9 = 7\]
  - between \([2, 2]\) and \([6, 7]\):
    \[4 = 2 \land 9 > 3 \land 9 < 7 \iff 4 = 2 \land 9 = 7 + 1\]
  - after \([6, 7]\):
    \[4 = 2 \land 9 > 8 \iff 4 = 2 \land 9 = 7 + 3\]
  - do not cross \([2, 2], [6, 7]\):
    \[9 \in [3, 3] \Rightarrow 4 \neq 2, 9 \in [7, 8] \Rightarrow 4 \neq 2\]

- **(if task $d$ is assigned on machine 3)**
  - no unavailability:
    \[4 = 3 \iff 4 = 3 \land 9 = 7\]

- **(if task $d$ is assigned on machine 4)**
  - before \([3, 4]\):
    \[4 = 4 \land 9 < 4 \iff 4 = 4 \land 9 = 7\]
  - after \([3, 4]\):
    \[4 = 4 \land 9 > 5 \iff 4 = 4 \land 9 = 7 + 2\]
  - do not cross \([3, 4]\):
    \[9 \in [4, 5] \Rightarrow 4 \neq 4\]

5.60 CARDINALITY_ATLEAST

**Origin**
Derived from GLOBAL_CARDINALITY.

**Constraint**
CARDINALITY_ATLEAST(ATLEAST, VARIABLES, VALUES)

**Arguments**
- ATLEAST : dvar
- VARIABLES : collection(var−dvar)
- VALUES : collection(val−int)

**Restrictions**
- ATLEAST ≥ 0
- ATLEAST ≤ |VARIABLES|
- required(VARIABLES, var)
- required(VARIABLES, val)
- distinct(VARIABLES, val)

**Purpose**
ATLEAST is the minimum number of time that a value of VALUES is taken by the variables of the collection VARIABLES.

**Example**
\[(1, (3, 3, 8), (3, 8))\]

In this example, values 3 and 8 are respectively used 2, and 1 times. The CARDINALITY_ATLEAST constraint holds since its first argument ATLEAST = 1 is assigned to the minimum number of time that values 3 and 8 occur in the collection \(\langle 3, 3, 8 \rangle\).

**Typical**
- ATLEAST > 0
- ATLEAST < |VARIABLES|
- |VARIABLES| > 1
- |VALUES| > 0
- |VALUES| > |VARIABLES|

**Symmetries**
- Items of VARIABLES are **permutable**.
- Items of VALUES are **permutable**.
- An occurrence of a value of VARIABLES.var that does not belong to VALUES.val can be **replaced** by any other value that also does not belong to VALUES.val.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be **swapped**; all occurrences of a value in VARIABLES.var or VALUES.val can be **renamed** to any unused value.

**Arg. properties**
Functional dependency: ATLEAST determined by VARIABLES and VALUES.

**Usage**
An application of the CARDINALITY_ATLEAST constraint is to enforce a minimum use of values.
Remark
This is a restricted form of a variant of an AMONG constraint and of the GLOBAL_CARDINALITY constraint. In the original GLOBAL_CARDINALITY constraint, one specifies for each value its minimum and maximum number of occurrences.

Algorithm
See GLOBAL_CARDINALITY [353].

See also
generalisation: GLOBAL_CARDINALITY (single count variable replaced by an individual count variable for each value).

Keywords
application area: assignment.

characteristic of a constraint: automaton, automaton with array of counters.

constraint arguments: pure functional dependency.

constraint type: value constraint.

filtering: arc-consistency.

final graph structure: acyclic, bipartite, no loop.

modelling: functional dependency, at least.

</tbody>
</table>

**Arc generator**

\[ \text{PRODUCT} \rightarrow \text{collection}(\text{variables}, \text{values}) \]

**Arc arity**

2

**Arc constraint(s)**

\[ \text{variables}.\text{var} \neq \text{values}.\text{val} \]

**Graph property(ies)**

\[ \text{MAX_ID} = |\text{VARIABLES}| - \text{ATLEAST} \]

**Graph class**

- ACYCLIC
- BIPARTITE
- NO_LOOP

**Graph model**

Using directly the graph property \( \text{MIN_ID} = \text{ATLEAST} \), and replacing the disequality of the arc constraint by an equality does not work since it ignores values that are not assigned to any variable. This comes from the fact that isolated vertices are removed from the final graph.

Parts (A) and (B) of Figure 5.153 respectively show the initial and final graph associated with the Example slot. Since we use the \( \text{MAX_ID} \) graph property, the vertex with the maximum number of predecessors (i.e., namely two predecessors) is stressed with a double circle. As a consequence the first argument \( \text{ATLEAST} \) of the \text{CARDINALITY_ATLEAST} constraint is assigned to the total number of variables 3 minus 2.

**Figure 5.153:** Initial and final graph of the \text{CARDINALITY_ATLEAST} constraint
Figure 5.154 depicts the automaton associated with the \texttt{CARDINALITY\_ATLEAST} constraint. To each variable $VAR_i$ of the collection $\text{VARIABLES}$ corresponds a 0-1 signature variable $S_i$. The following signature constraint links $VAR_i$ and $S_i$: $VAR_i \in VALUES \Leftrightarrow S_i$.

Figure 5.154: Automaton of the \texttt{CARDINALITY\_ATLEAST} constraint
5.61 CARDINALITY_ATMOST

Origin
Derived from GLOBAL_CARDINALITY.

Constraint
CARDINALITY_ATMOST(ATMOST, VARIABLES, VALUES)

Arguments
ATMOST : dvar
VARIABLES : collection(var−dvar)
VALUES : collection(val−int)

Restrictions
ATMOST ≥ 0
ATMOST ≤ |VARIABLES|
required(VARIABLES, var)
required(VARIABLES, val)
distinct(VARIABLES, val)

Purpose
ATMOST is the maximum number of occurrences of each value of VALUES within the variables of the collection VARIABLES.

Example
(2, (2, 1, 7, 1, 2), (5, 7, 2, 9))

In this example, values 5, 7, 2 and 9 occur respectively 0, 1, 2 and 0 times within the collection (2, 1, 7, 1, 2). As a consequence, the CARDINALITY_ATMOST constraint holds since its first argument ATMOST is assigned to the maximum number of occurrences 2.

Typical
ATMOST > 0
ATMOST < |VARIABLES|
|VARIABLES| > 1
|VALUES| > 0
|VARIABLES| ≥ |VALUES|

Symmetries
- Items of VARIABLES are permutable.
- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES var that does not belong to VALUES val can be replaced by any other value that also does not belong to VALUES val.
- All occurrences of two distinct values in VARIABLES var or VALUES val can be swapped; all occurrences of a value in VARIABLES var or VALUES val can be renamed to any unused value.

Arg. properties
Functional dependency: ATMOST determined by VARIABLES and VALUES.

Usage
An application of the CARDINALITY_ATMOST constraint is to enforce a maximum use of values.
Remark
This is a restricted form of a variant of the AMONG constraint and of the GLOBAL_CARDINALITY constraint. In the original GLOBAL_CARDINALITY constraint, one specifies for each value its minimum and maximum number of occurrences.

Algorithm
See GLOBAL_CARDINALITY [353].

See also
generalisation: GLOBAL_CARDINALITY (single count variable replaced by an individual count variable for each value), MULTI_INTERDISTANCE (window of size 1 replaced by window of DIST consecutive values).
implied by: AMONG.

Keywords
application area: assignment.
characteristic of a constraint: automaton, automaton with array of counters.
constraint arguments: pure functional dependency.
constraint type: value constraint.
filtering: arc-consistency.
final graph structure: acyclic, bipartite, no loop.
modelling: at most, functional dependency.
Parts (A) and (B) of Figure 5.155 respectively show the initial and final graph associated with the Example slot. Since we use the MAX.ID graph property, the vertex that has the maximum number of predecessor is stressed with a double circle.

Figure 5.155: Initial and final graph of the CARDINALITY_ATMOST constraint
Figure 5.156 depicts the automaton associated with the **CARDINALITY_ATMOST** constraint. To each variable \( \text{VAR}_i \) of the collection \( \text{VARIABLES} \) corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i \in \text{VALUES} \Leftrightarrow S_i \).

\[
\begin{align*}
\text{ARITH}(C; \leq, \text{ATMOST}) \\
\{ C[.] \leftarrow 0 \} & \overset{\text{IN}(\text{VAR}_i, \text{VALUES}), \{ C[\text{VAR}_i] \leftarrow C[\text{VAR}_i] + 1 \}}{\longrightarrow} \text{NOT IN}(\text{VAR}_i, \text{VALUES})
\end{align*}
\]

CARDINALITY_ATMOST_PARTITION
### 5.63 CHANGE

**Origin**: CHIP

**Constraint**: \( \text{CHANGE}(\text{NCHANGE}, \text{VARIABLES}, \text{CTR}) \)

**Synonyms**: NBCHANGES, SIMILARITY.

**Arguments**

- \( \text{NCHANGE} : \text{dvar} \)
- \( \text{VARIABLES} : \text{collection}(\text{var} - \text{dvar}) \)
- \( \text{CTR} : \text{atom} \)

**Restrictions**

- \( \text{NCHANGE} \geq 0 \)
- \( \text{NCHANGE} < |\text{VARIABLES}| \)
- \( \text{required}(\text{VARIABLES}, \text{var}) \)
- \( \text{CTR} \in [\neq, <, \geq, >, \leq] \)

**Purpose**

\( \text{NCHANGE} \) is the number of times that constraint \( \text{CTR} \) holds on consecutive variables of the collection \( \text{VARIABLES} \).

**Example**

\( (3, \langle 4, 3, 4, 1 \rangle, \neq) \) \quad \text{and} \quad \text{CHANGE}(3, \langle 4, 3, 4, 1 \rangle, \neq)

\( (1, \langle 1, 2, 4, 3, 7 \rangle, >) \) \quad \text{and} \quad \text{CHANGE}(1, \langle 1, 2, 4, 3, 7 \rangle, >)

In the first example the changes are located between values 4 and 3, 3 and 4, 4 and 1. Consequently, the corresponding CHANGE constraint holds since its first argument \( \text{NCHANGE} \) is fixed to value 3.

In the second example the unique change occurs between values 4 and 3. Consequently, the corresponding CHANGE constraint holds since its first argument \( \text{NCHANGE} \) is fixed to 1.

**Typical**

- \( \text{NCHANGE} > 0 \)
- \( |\text{VARIABLES}| > 1 \)
- \( \text{range}(\text{VARIABLES.var}) > 1 \)
- \( \text{CTR} \in [\neq] \)

**Symmetry**

One and the same constant can be added to the \text{var} attribute of all items of \( \text{VARIABLES} \).

**Arg. properties**

- **Functional dependency**: \( \text{NCHANGE} \) determined by \( \text{VARIABLES} \) and \( \text{CTR} \).
- **Contractible** wrt. \( \text{VARIABLES} \) when \( \text{CTR} \in [\neq, <, \geq, >, \leq] \) and \( \text{NCHANGE} = 0 \).
- **Contractible** wrt. \( \text{VARIABLES} \) when \( \text{CTR} \in [\neq, <, \geq, >, \leq] \) and \( \text{NCHANGE} = |\text{VARIABLES}| - 1 \).

**All solutions**

Figure 5.158 gives all solutions to the following non ground instance of the CHANGE constraint: \( \text{NCHANGE} \in [0, 1], \text{V}1 \in [2, 3], \text{V}2 \in [1, 2], \text{V}3 \in [4, 5], \text{V}4 \in [2, 4], \text{CHANGE}(\text{NCHANGE}, \langle \text{V}1, \text{V}2, \text{V}3, \text{V}4 \rangle, >) \).
Figure 5.158: All solutions corresponding to the non ground example of the CHANGE constraint (with CTR set to $>$) of the All solutions slot; each change is shown by a color change between two consecutive values.

Usage
This constraint can be used in the context of timetabling problems in order to put an upper limit on the number of changes of job types during a given period.

Remark
A similar constraint appears in [314, page 338] under the name of SIMILARITY constraint. The difference consists of replacing the arithmetic constraint CTR by a binary constraint. When CTR is equal to $\neq$ this constraint is called NBCHANGES in [416].

Algorithm
A first incomplete algorithm is described in [32]. The sketch of a filtering algorithm for the conjunction of the CHANGE and the STRETCH constraints based on dynamic programming achieving arc-consistency is mentioned by L. Hellsten in [219, page 56].

Reformulation
The CHANGE constraint can be reformulated with the SEQ BIN constraint [321] that we now introduce. Given N a domain variable, $X$ a sequence of domain variables, and C and B two binary constraints, SEQ BIN(N, $X$, C, B) holds if (1) N is equal to the number of C-stretches in the sequence $X$, and (2) B holds on any pair of consecutive variables in $X$. A C-stretch is a generalisation of the notion of stretch introduced by G. Pesant [316], where the equality constraint is made explicit by replacing it by a binary constraint C, i.e., a C-stretch is a maximal length subsequence of $X$ for which the binary constraint C is satisfied on consecutive variables. CHANGE(N, VARIABLES, CTR ) can be reformulated as $N = N_1 - 1 \land$ SEQ BIN($N_1$, $X$, $\neg$ CTR , true), where true is the universal constraint.

Used in
PATTERN.

See also
- common keyword: CHANGE_PARTITION, CIRCULAR_CHANGE (number of changes in a sequence of variables with respect to a binary constraint), CYCLIC_CHANGE, CYCLIC_CHANGE_JOKER (number of changes), SMOOTH (number of changes in a sequence of variables with respect to a binary constraint).
- generalisation: CHANGE_PAIR (variable replaced by pair of variables), CHANGEVECTORS (variable replaced by vector).
- shift of concept: DISTANCE_CHANGE, LONGEST_CHANGE.

Keywords
- characteristic of a constraint: automaton, automaton with counters, non-deterministic automaton.

Arc constraint(s) variables1.$\text{var}$ $\text{CTR}$ variables2.$\text{var}$
Graph property(ies) NARC = NCHANGE
Graph class
  • ACYCLIC
  • BIPARTITE
  • NO LOOP

Graph model
Since we are only interested by the constraints linking two consecutive items of the collection VARIABLES we use $PATH$ to generate the arcs of the initial graph.

Parts (A) and (B) of Figure 5.159 respectively show the initial and final graph of the first example of the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold.

Figure 5.159: Initial and final graph of the CHANGE constraint
Figure 5.160 depicts a first automaton that only accepts all the solutions to the CHANGE constraint. This automaton uses a counter in order to record the number of satisfied constraints of the form $\text{VAR}_i \mapsto \text{CTR} \mapsto \text{VAR}_{i+1}$ already encountered. To each pair of consecutive variables $(\text{VAR}_i, \text{VAR}_{i+1})$ of the collection VARIABLES corresponds a 0-1 signature variable $S_i$. The following signature constraint links $\text{VAR}_i$, $\text{VAR}_{i+1}$ and $S_i$: $\text{VAR}_i \mapsto \text{CTR} \mapsto \text{VAR}_{i+1} \Leftrightarrow S_i$.

![Figure 5.160: Automaton (with counter) of the CHANGE constraint](image)

Figure 5.160: Automaton (with counter) of the CHANGE constraint

Since the reformulation associated with the previous automaton is not Berge-acyclic, we now describe a second counter free automaton that also only accepts all the solutions to the CHANGE constraint. Without loss of generality, assume that the collection of variables VARIABLES contains at least two variables (i.e., $|\text{VARIABLES}| \geq 2$). Let $n$ and $D$ respectively denote the number of variables of the collection VARIABLES, and the union of the domains of the variables of VARIABLES. Clearly, the maximum number of changes (i.e., the number of times the constraint $\text{VAR}_i \mapsto \text{CTR} \mapsto \text{VAR}_{i+1}$ holds) cannot exceed the quantity $m = \min(n - 1, \text{NCHANGE})$. The $(m + 1) \cdot |D| + 2$ states of the automaton that only accepts all the solutions to the CHANGE constraint are defined in the following way:

- We have an initial state labelled by $s_I$.
- We have $m \cdot |D|$ intermediate states labelled by $s_{ij}$ ($i \in D, j \in [0, m]$). The first subscript $i$ of state $s_{ij}$ corresponds to the value currently encountered. The second subscript $j$ denotes the number of already encountered satisfied constraints of the form $\text{VAR}_i \mapsto \text{CTR} \mapsto \text{VAR}_{i+1}$ from the initial state $s_I$ to the state $s_{ij}$.
- We have an accepting state labelled by $s_F$.

Four classes of transitions are respectively defined in the following way:
1. There is a transition, labelled by $i$, from the initial state $s_I$ to the state $s_{i0}$, ($i \in \mathcal{D}$).

2. There is a transition, labelled by $j$, from every state $s_{ij}$, ($i \in \mathcal{D}, j \in [0, m]$), to the accepting state $s_F$.

3. $\forall i \in \mathcal{D}, \forall j \in [0, m], \forall k \in \mathcal{D} \cap \{k \mid i \sim \text{CTR} \ k\}$ there is a transition labelled by $k$ from $s_{ij}$ to $s_{kj}$ (i.e., the counter $j$ does not change for values $k$ such that constraint $i \sim \text{CTR} \ k$ does not hold).

4. $\forall i \in \mathcal{D}, \forall j \in [0, m - 1], \forall k \in \mathcal{D} \setminus \{k \mid i \sim \text{CTR} \ k\}$ there is a transition labelled by $k$ from $s_{ij}$ to $s_{kj+1}$ (i.e., the counter $j$ is incremented by +1 for values $k$ such that constraint $i \sim \text{CTR} \ k$ holds).

We have $|\mathcal{D}|$ transitions of type 1, $|\mathcal{D}| \cdot (m + 1)$ transitions of type 2, and at least $|\mathcal{D}|^2 \cdot m$ transitions of types 3 and 4. Since the maximum value of $m$ is equal to $n - 1$, in the worst case we have at least $|\mathcal{D}|^2 \cdot (n - 1)$ transitions. This leads to a worst case time complexity of $O(|\mathcal{D}|^2 \cdot n^2)$ if we use Pesant’s algorithm for filtering the regular constraint [317].

Figure 5.162 depicts the corresponding counter free non deterministic automaton associated with the change constraint under the hypothesis that (1) all variables of VARIABLES are assigned a value in \{0, 1, 2, 3\}, (2) $|\text{VARIABLES}|$ is equal to 4, and (3) $\text{CTR}$ is equal to $\neq$. 
The sequence of variables $\text{VAR}_1 \ \text{VAR}_2 \ \text{VAR}_3 \ \text{VAR}_4 \ \text{NCHANGE}$ is passed to the automaton

Figure 5.162: Counter free non deterministic automaton of the $\text{CHANGE}(\text{NCHANGE}, \langle \text{VAR}_1, \text{VAR}_2, \text{VAR}_3, \text{VAR}_4 \rangle, \neq)$ constraint assuming $\text{VAR}_i \in [0, 3]$ ($1 \leq i \leq 3$), with initial state $s_I$ and accepting state $s_F$. 
## 5.64 CHANGE_CONTINUITY

### Description

Origin: N. Beldiceanu

### Constraint

**CHANGE_CONTINUITY**

\[
\begin{align*}
\text{NB}_{-}\text{PERIOD}_{-}\text{CHANGE}, \\
\text{NB}_{-}\text{PERIOD}_{-}\text{CONTINUITY}, \\
\text{MIN}_{-}\text{SIZE}_{-}\text{CHANGE}, \\
\text{MAX}_{-}\text{SIZE}_{-}\text{CHANGE}, \\
\text{MIN}_{-}\text{SIZE}_{-}\text{CONTINUITY}, \\
\text{MAX}_{-}\text{SIZE}_{-}\text{CONTINUITY}, \\
\text{NB}_{-}\text{CHANGE}, \\
\text{NB}_{-}\text{CONTINUITY}, \\
\text{VARIABLES}, \\
\text{CTR}
\end{align*}
\]

### Arguments

- **NB_PERIOD_CHANGE**: dvar
- **NB_PERIOD_CONTINUITY**: dvar
- **MIN_SIZE_CHANGE**: dvar
- **MAX_SIZE_CHANGE**: dvar
- **MIN_SIZE_CONTINUITY**: dvar
- **MAX_SIZE_CONTINUITY**: dvar
- **NB_CHANGE**: dvar
- **NB_CONTINUITY**: dvar
- **VARIABLES**: collection(var−dvar)
- **CTR**: atom

### Restrictions

- **NB_PERIOD_CHANGE ≥ 0**
- **NB_PERIOD_CONTINUITY ≥ 0**
- **MIN_SIZE_CHANGE ≥ 0**
- **MAX_SIZE_CHANGE ≥ MIN_SIZE_CHANGE**
- **MIN_SIZE_CONTINUITY ≥ 0**
- **MAX_SIZE_CONTINUITY ≥ MIN_SIZE_CONTINUITY**
- **NB_CHANGE ≥ 0**
- **NB_CONTINUITY ≥ 0**
- **required(VARIABLES, var)**
- **CTR ∈ [=, ≠, <, ≥, >, ≤]**
On the one hand a change is defined by the fact that constraint VARIABLES[i].var CTR VARIABLES[i+1].var holds. On the other hand a continuity is defined by the fact that constraint VARIABLES[i].var CTR VARIABLES[i+1].var does not hold.

A period of change on variables

VARIABLES[i].var, VARIABLES[i+1].var, ..., VARIABLES[j].var (i < j)

is defined by the fact that all constraints VARIABLES[k].var CTR VARIABLES[k+1].var hold for k ∈ [i, j − 1].

A period of continuity on variables

VARIABLES[i].var, VARIABLES[i+1].var, ..., VARIABLES[j].var (i < j)

is defined by the fact that all constraints VARIABLES[k].var CTR VARIABLES[k+1].var do not hold for k ∈ [i, j − 1].

The constraint CHANGE_CONTINUITY holds if and only if:

- NB_PERIOD_CHANGE is equal to the number of periods of change,
- NB_PERIOD_CONTINUITY is equal to the number of periods of continuity,
- MIN_SIZE_CHANGE is equal to the number of variables of the smallest period of change,
- MAX_SIZE_CHANGE is equal to the number of variables of the largest period of change,
- MIN_SIZE_CONTINUITY is equal to the number of variables of the smallest period of continuity,
- MAX_SIZE_CONTINUITY is equal to the number of variables of the largest period of continuity,
- NB_CHANGE is equal to the total number of changes,
- NB_CONTINUITY is equal to the total number of continuities.

Example

(3, 2, 4, 2, 4, 6, 4, (1, 3, 1, 8, 8, 4, 7, 7, 7, 2), ≠)

Figure 5.163 makes clear the different parameters that are associated with the given example for the collection VARIABLES = (1, 3, 1, 8, 8, 4, 7, 7, 7, 2). We place character | for representing a change and a blank for a continuity. On top of the solution we represent the different periods of change, while below we show the different periods of continuity. The CHANGE_CONTINUITY constraint holds since:

- Its number of periods of change NB_PERIOD_CHANGE is equal to 3 (i.e., the 3 periods depicted on top of Figure 5.163),
- Its number of periods of continuity NB_PERIOD_CONTINUITY is equal to 2 (i.e., the 2 periods depicted below Figure 5.163),
- The number of variables of its smallest period of change MIN_SIZE_CHANGE is equal to 2 (i.e., the number of variables involved in the third period of change 7 2 depicted on top of Figure 5.163),
• The number of variables of the largest period of change $\max_{\text{SIZE CHANGE}}$ is equal to 4 (i.e., the number of variables involved in the first period of change 1 3 1 8 depicted on top of Figure 5.163),

• The number of variables of the smallest period of continuity $\min_{\text{SIZE CONTINUITY}}$ is equal to 2 (i.e., the number of variables involved in the first period 8 8 depicted below Figure 5.163),

• The number of variables of the largest period of continuity $\max_{\text{SIZE CONTINUITY}}$ is equal to 4 (i.e., the number of variables involved in the second period 7 7 7 7 depicted below Figure 5.163),

• The total number of changes $\nb_{\text{CHANGE}}$ is equal to 6 (i.e., the number of occurrences of character $|$ in Figure 5.163),

• The total number of continuities $\nb_{\text{CONTINUITY}}$ is equal to 4.

Figure 5.163: Illustration of the Example slot: periods of changes and periods of continuities wrt the constraint CTR equal to $\neq$

Typical

$\nb_{\text{PERIOD CHANGE}} > 0$
$\nb_{\text{PERIOD CONTINUITY}} > 0$
$\min_{\text{SIZE CHANGE}} > 0$
$\min_{\text{SIZE CONTINUITY}} > 0$
$\nb_{\text{CHANGE}} > 0$
$\nb_{\text{CONTINUITY}} > 0$
$|\text{VARIABLES}| > 0$
$\text{range}(\text{VARIABLES}.\text{var}) > 1$
$\text{CTR} \in [\neq]$

Symmetry

One and the same constant can be added to the var attribute of all items of VARIABLES.
### Arg. properties

- Functional dependency: `NB_PERIOD_CHANGE` determined by `VARIABLES` and `CTR`.
- Functional dependency: `NB_PERIOD_CONTINUITY` determined by `VARIABLES` and `CTR`.
- Functional dependency: `MIN_SIZE_CHANGE` determined by `VARIABLES` and `CTR`.
- Functional dependency: `MAX_SIZE_CHANGE` determined by `VARIABLES` and `CTR`.
- Functional dependency: `MIN_SIZE_CONTINUITY` determined by `VARIABLES` and `CTR`.
- Functional dependency: `MAX_SIZE_CONTINUITY` determined by `VARIABLES` and `CTR`.
- Functional dependency: `NB_CHANGE` determined by `VARIABLES` and `CTR`.
- Functional dependency: `NB_CONTINUITY` determined by `VARIABLES` and `CTR`.

### Remark

If the variables of the collection `VARIABLES` have to take distinct values between 1 and the total number of variables, we have what is called a permutation. In this case, if we choose the binary constraint `<`, then `MAX_SIZE_CHANGE` gives the size of the longest run of the permutation; a run is a maximal increasing contiguous subsequence in a permutation.

### See also

**common keyword:** GROUP, GROUP_SKIP_ISOLATED_ITEM, STRETCH_PATH (*timetabling constraint*).

### Keywords

**characteristic of a constraint:** automaton, automaton with counters, automaton with same input symbol.

**combinatorial object:** sequence, run of a permutation, permutation.

**constraint arguments:** reverse of a constraint.

**constraint network structure:** sliding cyclic(1) constraint network(2), sliding cyclic(1) constraint network(3).

**constraint type:** timetabling constraint.

**filtering:** glue matrix.

**final graph structure:** connected component, apportion, acyclic, bipartite, no loop.

**modelling:** functional dependency.
We use two graph constraints to respectively catch the constraints on the period of changes and of the period of continuities. In both case each period corresponds to a connected component of the final graph.

Parts (A) and (B) of Figure 5.164 respectively show the initial and final graph associated with the first graph constraint of the Example slot.
Figure 5.164: Initial and final graph of the CHANGE_CONTINUITY constraint
Figures 5.165, 5.166, 5.169, 5.170, 5.173, 5.174 and 5.177 depict the automata associated with the different graph parameters of the CHANGE_CONTINUITY constraint. For the automata that respectively compute \( \text{NB}_\text{PERIOD_CHANGE} \), \( \text{NB}_\text{PERIOD_CONTINUITY} \), \( \text{MIN}_\text{SIZE_CHANGE} \), \( \text{MIN}_\text{SIZE_CONTINUITY} \), \( \text{MAX}_\text{SIZE_CHANGE} \), \( \text{MAX}_\text{SIZE_CONTINUITY} \), \( \text{NB}_\text{CHANGE} \) and \( \text{NB}_\text{CONTINUITY} \) we have a 0-1 signature variable \( S_i \) for each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection \( \text{VARIABLES} \). The following signature constraint links \( \text{VAR}_i, \text{VAR}_{i+1} \) and \( S_i \): \( \text{VAR}_i \text{CTR} \text{VAR}_{i+1} \Leftrightarrow S_i \).

\[
\text{STATE SEMANTICS}
\]

\[

5.65 CHANGE_PAIR

Origin
Derived from CHANGE.

Constraint
CHANGE_PAIR(NCHANGE, PAIRS, CTRX, CTRY)

Arguments
NCHANGE : dvar
PAIRS : collection(x−dvar,y−dvar)
CTRX : atom
CTRY : atom

Restrictions
NCHANGE ≥ 0
NCHANGE < |PAIRS|
required(PAIRS,[x,y])
CTRX ∈ [=,≠,<,>,≤]
CTRY ∈ [=,≠,<,>,≤]

Purpose
NCHANGE is the number of times that the following disjunction holds: (X_1 CTRX X_2) ∨ (Y_1 CTRY Y_2), where (X_1,Y_1) and (X_2,Y_2) correspond to consecutive pairs of variables of the collection PAIRS.

Example
\[
\begin{pmatrix}
  x - 3 & y - 5, \\
  x - 3 & y - 7, \\
  x - 3 & y - 7, \\
  x - 3 & y - 8, \\
  x - 3 & y - 4, \\
  x - 3 & y - 7, \\
  x - 1 & y - 3, \\
  x - 1 & y - 6, \\
  x - 1 & y - 6, \\
  x - 3 & y - 7
\end{pmatrix}, \neq, >
\]

In the example we have the following 3 changes:

- One change between pairs x − 3 y − 8 and x − 3 y − 4 since 3 ≠ 3 ∨ 8 > 4,
- One change between pairs x − 3 y − 7 and x − 1 y − 3 since 3 ≠ 1 ∨ 7 > 3,
- One change between pairs x − 1 y − 6 and x − 3 y − 7 since 1 ≠ 3 ∨ 6 > 7.

Consequently the CHANGE_PAIR constraint holds since its first argument NCHANGE is assigned value 3.

Typical
NCHANGE > 0
|PAIRS| > 1
range(PAIRS.x) > 1
range(PAIRS.y) > 1
Symmetries
- One and the same constant can be added to the $x$ attribute of all items of PAIRS.
- One and the same constant can be added to the $y$ attribute of all items of PAIRS.

Arg. properties
Functional dependency: $NCHANGE$ determined by $PAIRS$, $CTRX$ and $CTRY$.

Usage
Here is a typical example where this constraint is useful. Assume we have to produce a set of cables. A given quality and a given cross-section that respectively correspond to the $x$ and $y$ attributes of the previous pairs of variables characterise each cable. The problem is to sequence the different cables in order to minimise the number of times two consecutive wire cables $C_1$ and $C_2$ verify the following property: $C_1$ and $C_2$ do not have the same quality or the cross section of $C_1$ is greater than the cross section of $C_2$.

### 5.66 CHANGE_PARTITION

#### Description

**Origin**  
Derived from CHANGE.

**Constraint**  
\( \text{CHANGE\_PARTITION}(\text{NCHANGE, VARIABLES, PARTITIONS}) \)

**Type**  
VALUES : collection(val-int)

**Arguments**  
- \( \text{NCHANGE} \) : dvar
- \( \text{VARIABLES} \) : collection(var-dvar)
- \( \text{PARTITIONS} \) : collection(p-VALUES)

**Restrictions**  
- \(|\text{VALUES}| \geq 1\)
- \(\text{required}(\text{VALUES}, \text{val})\)
- \(\text{distinct}(\text{VALUES}, \text{val})\)
- \(\text{NCHANGE} \geq 0\)
- \(\text{NCHANGE} < |\text{VARIABLES}|\)
- \(\text{required}(\text{VARIABLES}.\text{var})\)
- \(\text{required}(\text{PARTITIONS}.\text{p})\)
- \(|\text{PARTITIONS}| \geq 2\)

**Purpose**  
\(\text{NCHANGE}\) is the number of times that the following constraint holds: \(X\) and \(Y\) do not belong to the same partition of the collection \(\text{PARTITIONS}\), where \(X\) and \(Y\) correspond to consecutive variables of the collection \(\text{VARIABLES}\).

**Example**  
\[
(2, \langle 6, 6, 2, 1, 3, 3, 1, 6, 2, 2, 2 \rangle, \\
\langle p - \langle 1, 3 \rangle, p - \langle 4 \rangle, p - \langle 2, 6 \rangle \rangle)
\]

In the example we have the following two changes:

- One change between values 2 and 1 (since 2 and 1 respectively belong to the third and the first partition).
- One change between values 1 and 6 (since 1 and 6 respectively belong to the first and the third partition).

Consequently the CHANGE_PARTITION constraint holds since its first argument \(\text{NCHANGE}\) is assigned to 2.

**Typical**  
\(\text{NCHANGE} > 0\)
- \(|\text{VARIABLES}| > 1\)
- \(\text{range}(\text{VARIABLES}.\text{var}) > 1\)
- \(|\text{VARIABLES}| > |\text{PARTITIONS}|\)
Symmetries

- Items of VARIABLES can be reversed.
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.
- An occurrence of a value of VARIABLES.var can be replaced by any other value that also belongs to the same partition of PARTITIONS.

Arg. properties

Functional dependency: NCHANGE determined by VARIABLES and PARTITIONS.

Usage

This constraint is useful for the following problem: Assume you have to produce a set of orders, each order belonging to a given family. In the context of the Example slot we have three families that respectively correspond to values 1, 3, to value 4 and to values 2, 6. We would like to sequence the orders in such a way that we minimise the number of times two consecutive orders do not belong to the same family.

Algorithm

[32].

Figure 5.183: Initial and final graph of the CHANGE_PARTITION constraint
### 5.67 CHANGE_VECTORS

#### Description

**Origin**
- Derived from `CHANGE`

**Constraint**
- `CHANGE_VECTORS(NCHANGE, VECTORS, CTRS)`

**Types**
- `VECTOR : collection(var−dvar)`
- `CTR : atom`

**Arguments**
- `NCHANGE : dvar`
- `VECTORS : collection(vec−VECTOR)`
- `CTRS : collection(ctr−CTR)`

**Restrictions**
- `|VECTOR| ≥ 1`
- `required(VECTOR, var)`
- `CTR ∈ [=, ≠, <, ≥, >, ≤]`
- `NCHANGE ≥ 0`
- `NCHANGE < |VECTORS|`
- `required(VECTORS, vec)`
- `same_size(VECTORS, vec)`
- `required(CTRS, ctr)`
- `|CTRS| = |VECTOR|`

Let us note `VECTOR_1, VECTOR_2, . . . , VECTOR_m` the vectors of the `VECTORS` collection, and `d` the number of components of each vector (all vectors have the same size). `NCHANGE` is the number of times that the following disjunctions holds where `i ∈ [1, n − 1]`

\[
(VECTOR_i, vec[1] \text{ CTRS}_i[1] \text{ VECTOR}_{i+1}.vec[1]) \lor \\
(VECTOR_i, vec[2] \text{ CTRS}_i[2] \text{ VECTOR}_{i+1}.vec[2]) \lor \\
\vdots \\
(VECTOR_i, vec[d] \text{ CTRS}_i[d] \text{ VECTOR}_{i+1}.vec[d]).
\]

**Purpose**

#### Example

```
\begin{pmatrix}
\text{vec} - (4, 0), \\
\text{vec} - (4, 0), \\
\text{vec} - (4, 5), \\
\text{vec} - (3, 4), \\
\text{vec} - (3, 4), \\
\text{vec} - (3, 4), \\
\text{vec} - (3, 0), \\
\text{vec} - (4, 0), \\
(\neq, \neq)
\end{pmatrix}
```

In the example we have the following 3 changes:
- One change between \(4, 0\) and \(4, 5\) since \(4 \neq 4 \lor 0 \neq 5\).
- One change between \(4, 5\) and \(3, 4\) since \(4 \neq 3 \lor 5 \neq 4\).
• One change between \(3, 4\) and \(4, 0\) since \(3 \neq 4 \lor 4 \neq 0\).

Consequently the \textsc{changeVectors} constraint holds since its first argument \(\text{NCHANGE}\) is assigned value 3.

Typical

\[
\begin{array}{l}
\text{CTR} \in [ \neq ] \\
|\text{VECTOR}| > 1 \\
\text{NCHANGE} > 0 \\
|\text{VECTORS}| > 1
\end{array}
\]

Arg. properties

Functional dependency: \(\text{NCHANGE}\) determined by \(\text{VECTORS}\) and \(\text{CTRS}\).

See also

specialisation: \textsc{change} (vector replaced by variable), \textsc{changePair} (vector replaced by pair of variables).

Keywords

characteristic of a constraint: automaton, automaton with counters, vector.
constraint arguments: pure functional dependency.
constraint network structure: Berge-acyclic constraint network.
modelling: number of changes, functional dependency.
5.68 CIRCUIT

Origin [267]

Constraint CIRCUIT(NODES)

Synonyms ATOUR, CYCLE.

Argument NODES : collection(index-int, succ-dvar)

Restrictions required(NODES, [index, succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ ≤ |NODES|

Purpose Enforce to cover a digraph G described by the NODES collection with one circuit visiting once all vertices of G.

Example

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} - 2, \\
\text{index} - 2 & \text{succ} - 3, \\
\text{index} - 3 & \text{succ} - 4, \\
\text{index} - 4 & \text{succ} - 1
\end{pmatrix}
\]

The CIRCUIT constraint holds since its NODES argument depicts the following Hamiltonian circuit visiting successively the vertices 1, 2, 3, 4 and 1.

All solutions Figure 5.184 gives all solutions to the following non ground instance of the CIRCUIT constraint: \(S_1 \in [3, 4], S_2 \in [1, 2], S_3 \in [1, 4], S_4 \in [2, 4], \) CIRCUIT((\((S_1, S_2, S_3, S_4)\)).

All solutions Figure 5.184: All solutions corresponding to the non ground example of the CIRCUIT constraint of the All solutions slot; in the left-hand side the index attributes are displayed as indices of the succ attribute, while in the right-hand side they are directly displayed within each node.

Typical |NODES| > 2
Symmetry

Items of NODES are permutable.

Remark

In the original CIRCUIT constraint of CHIP the index attribute was not explicitly present. It was implicitly defined as the position of a variable in a list.

Within the context of linear programming [6] this constraint was introduced under the name ATOUR. In the same context [226, page 380] provides continuous relaxations of the CIRCUIT constraint.

Within the KOALOG constraint system this constraint is called CYCLE.

Algorithm

Since all nodes variables of the NODES collection have to take distinct values one can reuse the algorithms associated with the ALLDIFFERENT constraint. A second necessary condition is to have no more than one strongly connected component. Pruning for enforcing this condition can be done by forcing all strong bridges to belong to the final solution, since otherwise the strongly connected component would be broken apart. A third necessary condition is that, if the graph is bipartite then the number of vertices of each class should be identical. Consequently if the number of vertices is odd (i.e., |NODES| is odd) the graph should not be bipartite. Further necessary conditions (useful when the graph is sparse) combining the fact that we have a perfect matching and a single strongly connected component can be found in [392]. These conditions forget about the orientation of the arcs of the graph and characterise new required elementary chains. A typical pattern involving four vertices is depicted by Figure 5.185 where we assume that:

- There is an elementary chain between c and d (depicted by a dashed edge),
- b has exactly 3 neighbours.

In this context the edge between a and b is mandatory in any covering (i.e., the arc from a to b or the arc from b to a) since otherwise a small circuit involving b, c and d would be created.

When the graph is planar [228][147] one can also use as a necessary condition discovered by Grinberg [210] for pruning.

Finally, another approach based on the notion of 1-toughness [125] was proposed in [247] and evaluated for small graphs (i.e., graphs with up to 15 vertices).
Figure 5.185: Reasoning about elementary chains and degrees: if we have an elementary chain between \( c \) and \( d \) and if \( b \) has 3 neighbours then the edge \((a, b)\) is mandatory.
Reformulation

Let \( n \) and \( s_1, s_2, \ldots, s_n \) respectively denote the number of vertices (i.e., |NODES|) and the successor variables associated with vertices \( 1, 2, \ldots, n \). The CIRCUIT constraint can be reformulated as a conjunction of one DOMAIN constraint, two ALLDIFFERENT constraints, and \( n \) ELEMENT constraints.

- First, we state an ALLDIFFERENT\((s_1, s_2, \ldots, s_n)\) constraint for enforcing distinct values to be assigned to the successor variables.

- Second, the key idea is, starting from vertex 1, to successively extract the vertices \( t_1, t_2, \ldots, t_{n-1} \) of the circuit until we come back on vertex 1, where \( t_i \) (with \( i \in [2, n - 1] \)) denotes the successor of \( t_{i-1} \) and \( t_1 \) the successor of vertex 1. Since we have a single circuit all the \( t_1, t_2, \ldots, t_{n-1} \) should be different from 1. Consequently we state a DOMAIN\((t_1, t_2, \ldots, t_{n-1}, 2, n)\) constraint for declaring their initial domains. To express the link between consecutive \( t_i \) we also state a conjunction of \( n \) ELEMENT constraints of the form:

  \[
  \text{ELEMENT}(1, \langle s_1, s_2, \ldots, s_n \rangle, t_1), \\
  \text{ELEMENT}(t_1, \langle s_1, s_2, \ldots, s_n \rangle, t_2), \\
  \ldots \\
  \text{ELEMENT}(t_{n-1}, \langle s_1, s_2, \ldots, s_n \rangle, 1).
  \]

- Finally we add a redundant constraint for stating that all \( t_i \) (with \( i \in [1, n - 1] \)) are distinct, i.e. ALLDIFFERENT\((t_1, t_2, \ldots, t_{n-1})\).

**Systems**

- CIRCUIT in Gecode,
- CIRCUIT in JaCoP,
- CIRCUIT in MiniZinc,
- CIRCUIT in SICStus.

**See also**

- common keyword: ALLDIFFERENT (permutation), CIRCUIT_CLUSTER (graph)
constraint, one_succ), PATH(graph partitioning constraint, one_succ),
PROPER_CIRCUIT(permutation, one_succ), TOUR(graph partitioning constraint, Hamiltonian).

generalisation: CYCLE(introduce a variable for the number of circuits).

implies: ALLDIFFERENT, PROPER_CIRCUIT, TWIN.

implies (items to collection): LEX_ALLDIFFERENT.

related: STRONGLY_CONNECTED.

Keywords

combinatorial object: permutation.

constraint type: graph constraint, graph partitioning constraint.

filtering: linear programming, planarity test, strong bridge, DFS-bottleneck.

final graph structure: circuit, one_succ.

problems: Hamiltonian.

puzzles: Euler knight.

Cond. implications

• CIRCUIT(NODES) implies CYCLE(NCYCLE, NODES)
  when NCYCLE = 1.

• CIRCUIT(NODES) with |NODES| > 1 implies DERANGEMENT(NODES).

• CIRCUIT(NODES) with |NODES| > 1 implies K_ALLDIFFERENT(VARS: NODES).

• CIRCUIT(NODES) implies PERMUTATION(VARIABLES: NODES).
The first graph property enforces to have a single strongly connected component containing $|\text{NODES}|$ vertices. The second graph property imposes to only have circuits. Since each vertex of the final graph has only one successor we do not need to use set variables for representing the successors of a vertex.

Parts (A) and (B) of Figure 5.186 respectively show the initial and final graph associated with the Example slot. The CIRCUIT constraint holds since the final graph consists of one circuit mentioning once every vertex of the initial graph.

Figure 5.186: Initial and final graph of the CIRCUIT constraint
5.69 CIRCUIT_CLUSTER

Origin
Inspired by [263].

Constraint
CIRCUIT_CLUSTER(NCIRCUIT, NODES)

Arguments
NCIRCUIT : dvar
NODES : collection(index-int, cluster-int, succ-dvar)

Restrictions
NCIRCUIT ≥ 1
NCIRCUIT ≤ |NODES|
required(NODES,[index, cluster, succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES, index)
NODES.succ ≥ 1
NODES.succ ≤ |NODES|

Purpose
Consider a digraph G, described by the NODES collection, such that its vertices are partitioned among several clusters. NCIRCUIT is the number of circuits containing more than one vertex used for covering G in such a way that each cluster is visited by exactly one circuit of length greater than 1.

Example

  \{ succ – 7 \},
  \{ succ – 8 \},
  \{ succ – 9 \}
\})
Both examples involve 9 vertices 1, 2, . . . , 9 such that vertices 1 and 2 belong to cluster number 1, vertices 3 and 4 belong to cluster number 2, vertices 5, 6 and 7 belong to cluster number 3, and vertices 8 and 9 belong to cluster number 4.

The first example involves only a single circuit containing more than one vertex (i.e., see in Figure 5.187 the circuit 2 → 4 → 5 → 8 → 2). The corresponding CIRCUIT_CLUSTER constraint holds since exactly one vertex of each cluster (i.e., vertex 2 for cluster 1, vertex 4 for cluster 2, vertex 5 for cluster 3, vertex 8 for cluster 4) belongs to this circuit.

The second example contains the two circuits 2 → 4 → 2 and 6 → 9 → 6 that both involve more than one vertex. The corresponding CIRCUIT_CLUSTER constraint holds since exactly one vertex of each cluster (i.e., see in Figure 5.188 vertex 2 in 2 → 4 → 2 for cluster 1, vertex 4 in 2 → 4 → 2 for cluster 2, vertex 6 in 6 → 9 → 6 for cluster 3, vertex 9 in 6 → 9 → 6 for cluster 4) belongs to these two circuits.

Typical

\[
\text{NCIRCUIT} < |\text{NODES}| \\
|\text{NODES}| > 2 \\
\text{range}(\text{NODES.cluster}) > 1
\]

Symmetry

Items of NODES are permutable.

Usage

A related abstraction in Operations Research was introduced in [263]. It was reported as the Generalised Travelling Salesman Problem (GTSP). The CIRCUIT_CLUSTER constraint differs from the GTSP because of the two following points:

- Each node of our graph belongs to a single cluster,
- We do not constrain the number of circuits to be equal to 1: The number of circuits should be equal to one of the values of the domain of the variable NCIRCUIT.
Figure 5.188: The same clusters as in the first example of the Example slot and a covering with two circuits corresponding to the second example of the Example slot.

See also  
**common keyword:** ALLDIFFERENT (*permutation*), CIRCUIT, CYCLE (*graph constraint, one_suc*).

**used in graph description:** ALLDIFFERENT, NVALUES.

**Keywords**  
**combinatorial object:** permutation.

**constraint type:** graph constraint.

**final graph structure:** strongly connected component, one_suc.

**modelling:** cluster.
In order to express the binary constraint linking two vertices one has to make explicit the identifier of each vertex as well as the cluster to which belongs each vertex. This is why the CIRCUIT.CLUSTER constraint considers objects that have the following three attributes:

- The attribute `index` that is the identifier of a vertex.
- The attribute `cluster` that is the cluster to which belongs a vertex.
- The attribute `succ` that is the unique successor of a vertex.

The partitioning of the clusters by different circuits is expressed in the following way:

- First note the condition `nodes1.succ ≠ nodes1.index` prevents the final graph of containing any loop. Moreover the condition `nodes1.succ = nodes2.index` imposes no more than one successor for each vertex of the final graph.
- The graph property `NTREE = 0` enforces that all vertices of the final graph belong to one circuit.
- The graph property `NSCC = NCIRCUIT` express the fact that the number of strongly connected components of the final graph is equal to `NCIRCUIT`.
- The constraint `ALLDIFFERENT(variables)` on the set `ALL_VERTICES` (i.e., all the vertices of the final graph) states that the cluster attributes of the vertices of the final graph should be pairwise distinct. This concretely means that no `cluster` should be visited more than once.
- The constraint `NVALUES(variables, =, size(NODES.cluster))` on the set `ALL_VERTICES` conveys the fact that the number of distinct values of the cluster attribute of the vertices of the final graph should be equal to the total number of clusters. This implies that each `cluster` is visited at least one time.

Parts (A) and (B) of Figure 5.189 respectively show the initial and final graph associated with the second example of the Example slot. Since we use the NSCC graph property, we show the two strongly connected components of the final graph. They respectively correspond to the two circuits 2 → 4 → 2 and 6 → 9 → 6. Since all the vertices belongs to a circuit we have that `NTREE = 0`. 
Figure 5.189: Initial and final graph of the CIRCUIT_CLUSTER constraint
### 5.70 CIRCULAR_CHANGE

#### Origin

Derived from CHANGE.

#### Constraint

\[
\text{CIRCULAR\_CHANGE}(\text{NCHANGE}, \text{VARIABLES}, \text{CTR})
\]

#### Arguments

- **NCHANGE**: `dvar`
- **VARIABLES**: `collection(var–dvar)`
- **CTR**: `atom`

#### Restrictions

- \(\text{NCHANGE} \geq 0\)
- \(\text{NCHANGE} \leq |\text{VARIABLES}|\)
- \(\text{required}(\text{VARIABLES}, \text{var})\)
- \(\text{CTR} \in […]\)

#### Purpose

\(\text{NCHANGE}\) is the number of times that \(\text{CTR}\) holds on consecutive variables of the collection \(\text{VARIABLES}\). The last and the first variables of the collection \(\text{VARIABLES}\) are also considered to be consecutive.

#### Example

\[
(4, (4, 3, 4, 1), \neq)
\]

In the example the changes within the \(\text{VARIABLES} = (4, 4, 3, 4, 1)\) collection are located between values 4 and 3, 3 and 4, 4 and 1, and 1 and 4 (i.e., since the third argument \(\text{CTR}\) of the CIRCULAR\_CHANGE constraint is set to \(\neq\), we count one change for each disequality constraint between two consecutive variables that holds). Consequently, the corresponding CIRCULAR\_CHANGE constraint holds since its first argument \(\text{NCHANGE}\) is fixed to 4.

#### All solutions

Figure 5.190 gives all solutions to the following non ground instance of the CIRCULAR\_CHANGE constraint: \(\text{NCHANGE} \in [0, 2], \text{V}_1 \in [2, 3], \text{V}_2 \in [1, 3], \text{V}_3 \in [3, 4], \text{V}_4 \in [2, 3], \text{V}_5 \in [3, 4], \text{CIRCULAR\_CHANGE}(\text{NCHANGE}, (\text{V}_1, \text{V}_2, \text{V}_3, \text{V}_4, \text{V}_5), \neq)\).

#### Typical

- \(\text{NCHANGE} > 0\)
- \(|\text{VARIABLES}| > 1\)
- \(\text{range}(\text{VARIABLES}.\text{var}) > 1\)
- \(\text{CTR} \in […]\)

#### Symmetries

- Items of \(\text{VARIABLES}\) can be shifted.
- One and the same constant can be added to the \text{var} attribute of all items of \(\text{VARIABLES}\).

#### Arg. properties

- **Functional dependency**: \(\text{NCHANGE}\) determined by \(\text{VARIABLES}\) and \(\text{CTR}\).

#### See also

- **common keyword**: CHANGE \((\text{number of changes})\).
Figure 5.190: All solutions corresponding to the non ground example of the CIRCULAR_CHANGE constraint of the All solutions slot; a missing arc between two consecutive nodes represents a change, i.e. a disequality constraint that is satisfied between two consecutive variables (the last and the first variables of a sequence are also consecutive).

**Keywords**

- **characteristic of a constraint**: cyclic, automaton, automaton with counters.
- **constraint arguments**: pure functional dependency.
- **constraint network structure**: circular sliding cyclic(1) constraint network(2).
- **constraint type**: timetabling constraint.
- **modelling**: number of changes, functional dependency.

**Graph model**

Since we are also interested in the constraint that links the last and the first variable we use the arc generator CIRCUIT to produce the arcs of the initial graph.

Parts (A) and (B) of Figure 5.191 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold.

Figure 5.191: Initial and final graph of the CIRCULAR_CHANGE constraint
Figure 5.192 depicts the automaton associated with the \texttt{CIRCULAR\_CHANGE} constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{(i \mod |\text{VARIABLES}|)+1})\) of the collection \texttt{VARIABLES} corresponds a 0-1 signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i, \text{VAR}_{(i \mod |\text{VARIABLES}|)+1}\) and \(S_i\): \(\text{VAR}_i \sim \text{CTR \ VAR}_{i+1} \Leftrightarrow S_i\).

\[
\begin{align*}
\text{VAR}_i & \sim \text{CTR \ VAR}_{i+1} \\
\{C \leftarrow 0\} & \rightarrow \text{s} \rightarrow \text{VAR}_i \sim \text{CTR \ VAR}_{i+1} \\
\{C \leftarrow C + 1\} & \rightarrow \text{s} \rightarrow \text{VAR}_i \sim \text{CTR \ VAR}_{i+1}
\end{align*}
\]

\texttt{NCHANGE} = \(C\)

5.71 CLAUSE_AND

Origin: Logic

Constraint: \( \text{CLAUSE\_AND(POSVARS, NEGVARS, VAR)} \)

Synonym: CLAUSE.

Arguments:
- \( \text{POSVARS} : \text{collection(var\_dvar)} \)
- \( \text{NEGVARS} : \text{collection(var\_dvar)} \)
- \( \text{VAR} : \text{dvar} \)

Restrictions:
- \(|\text{POSVARS}| + |\text{NEGVARS}| > 0\)
- \(\text{required}(\text{POSVARS}, \text{var})\)
- \(\text{POSVARS}\_\text{var} \geq 0\)
- \(\text{POSVARS}\_\text{var} \leq 1\)
- \(\text{required}(\text{NEGVARS}, \text{var})\)
- \(\text{NEGVARS}\_\text{var} \geq 0\)
- \(\text{NEGVARS}\_\text{var} \leq 1\)
- \(\text{VAR} \geq 0\)
- \(\text{VAR} \leq 1\)

Purpose:
Given a first collection of 0-1 variables \(\text{POSVARS} = U_1, U_2, \ldots, U_p\), a second collection of 0-1 variables \(\text{NEGVARS} = V_1, V_2, \ldots, V_n\), and a variable \(\text{VAR}\), enforce \(\text{VAR} = (U_1 \land U_2 \land \cdots \land U_p) \land (\neg V_1 \land \neg V_2 \land \cdots \land \neg V_n)\).

Example: \(\langle (1, 0), (0, 0) \rangle\)

Typical:
- \(|\text{POSVARS}| + |\text{NEGVARS}| > 1\)

Symmetries:
- Items of \(\text{POSVARS}\) are permutable.
- Items of \(\text{NEGVARS}\) are permutable.

Arg. properties:
- Extensible wrt. \(\text{POSVARS}\) when \(\text{VAR} = 0\).
- Extensible wrt. \(\text{NEGVARS}\) when \(\text{VAR} = 0\).

Remark:
The \text{CLAUSE\_OR} constraint is called CLAUSE in Gecode (http://www.gecode.org/).

Systems:
- REIFIEDAND in Choco, CLAUSE in Choco, CLAUSE in Gecode.

See also:
common keyword: \text{AND, CLAUSE\_OR (Boolean constraint)}.
Keywords

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

constraint type: Boolean constraint.

filtering: arc-consistency.
Figure 5.194 depicts the automaton associated with the CLAUSE_AND constraint:

- To the argument VAR of the CLAUSE_AND constraint corresponds the first signature variable.
- To each variable of the argument POSVARS corresponds a signature variable.
- Finally, to each variable VAR of the argument NEGVARS corresponds a signature variable that is the negation of VAR.

5.73 CLIQUE

Origin [170]

Constraint CLIQUE(SIZE_CLIQUE, NODES)

Arguments

\[
\begin{align*}
\text{SIZE_CLIQUE} & : \text{dvar} \\
\text{NODES} & : \text{collection(index-int, succ-svar)}
\end{align*}
\]

Restrictions

\[
\begin{align*}
\text{SIZE_CLIQUE} & \geq 0 \\
\text{SIZE_CLIQUE} & \leq |\text{NODES}| \\
\text{required} & (\text{NODES}, [\text{index}, \text{succ}]) \\
\text{NODES}.\text{index} & \geq 1 \\
\text{NODES}.\text{index} & \leq |\text{NODES}| \\
\text{distinct} & (\text{NODES}, \text{index}) \\
\text{NODES}.\text{succ} & \geq 1 \\
\text{NODES}.\text{succ} & \leq |\text{NODES}|
\end{align*}
\]

Purpose

Consider a digraph \( G \) described by the \( \text{NODES} \) collection: to the \( i^{th} \) item of the \( \text{NODES} \) collection corresponds the \( i^{th} \) vertex of \( G \); to each value \( j \) of the \( i^{th} \) \( \text{succ} \) variable corresponds an arc from the \( i^{th} \) vertex to the \( j^{th} \) vertex. Select a subset \( S \) of the vertices of \( G \) that forms a clique of size \( \text{SIZE_CLIQUE} \) (i.e., there is an arc between each pair of distinct vertices of \( S \)).

Example

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} - \emptyset, \\
\text{index} - 2 & \text{succ} - \{3, 5\}, \\
\text{index} - 3 & \text{succ} - \{2, 5\}, \\
\text{index} - 4 & \text{succ} - \emptyset, \\
\text{index} - 5 & \text{succ} - \{2, 3\}
\end{pmatrix}
\]

The CLIQUE constraint holds since the \( \text{NODES} \) collection depicts a clique involving 3 vertices (namely vertices 2, 3 and 5) and since its first argument \( \text{SIZE_CLIQUE} \) is set to the number of vertices of this clique.

Typical

\[
\begin{align*}
\text{SIZE_CLIQUE} & \geq 2 \\
\text{SIZE_CLIQUE} & < |\text{NODES}| \\
|\text{NODES}| & > 2
\end{align*}
\]

Symmetry Items of \( \text{NODES} \) are permutable.

Arg. properties Functional dependency: \( \text{SIZE_CLIQUE} \) determined by \( \text{NODES} \).

Algorithm [170], [358, 359]. The algorithm for finding maximum cliques in an undirected graph of C. Bron and J. Kerbosch [97] was adapted by J.-C. Régis to the context of constraint programming in his papers.

## 5.74 COLORED_MATRIX

### Origin
KOALOG

### Constraint
COLORED_MATRIX(C, L, K, MATRIX, CPROJ, LPROJ)

### Synonyms
COLOURED_MATRIX, CARDINALITY_MATRIX, CARD_MATRIX.

### Arguments
- **C**: int
- **L**: int
- **K**: int
- **MATRIX**: collection(column-int, line-int, var-dvar)
- **CPROJ**: collection(column-int, val-int, nocc-dvar)
- **LPROJ**: collection(line-int, val-int, nocc-dvar)

### Restrictions
- C ≥ 0
- L ≥ 0
- K ≥ 0
- required(MATRIX, [column, line, var])
- increasing_seq(MATRIX, [column, line])
- |MATRIX| = C * L + C + L + 1
- MATRIX.column ≥ 0
- MATRIX.column ≤ C
- MATRIX.line ≥ 0
- MATRIX.line ≤ L
- MATRIX.var ≥ 0
- MATRIX.var ≤ K
- required(CPROJ, [column, val, nocc])
- increasing_seq(CPROJ, [column, val])
- |CPROJ| = C * K + C + K + 1
- CPROJ.column ≥ 0
- CPROJ.column ≤ C
- CPROJ.val ≥ 0
- CPROJ.val ≤ K
- required(LPROJ, [line, val, nocc])
- increasing_seq(LPROJ, [line, val])
- |LPROJ| = L * K + L + K + 1
- LPROJ.line ≥ 0
- LPROJ.line ≤ L
- LPROJ.val ≥ 0
- LPROJ.val ≤ K

### Purpose
Given a matrix of domain variables, imposes a **GLOBAL_CARDINALITY** constraint involving cardinality variables on each column and each row of the matrix.
Example

\[
\begin{pmatrix}
\text{column} - 0 & \text{line} - 0 & \text{var} - 3, \\
\text{column} - 0 & \text{line} - 1 & \text{var} - 1, \\
\text{column} - 0 & \text{line} - 2 & \text{var} - 3, \\
\text{column} - 1 & \text{line} - 0 & \text{var} - 4, \\
\text{column} - 1 & \text{line} - 1 & \text{var} - 4, \\
\text{column} - 1 & \text{line} - 2 & \text{var} - 3 \\
\end{pmatrix},
\begin{pmatrix}
\text{column} - 0 & \text{val} - 0 & \text{nocc} - 0, \\
\text{column} - 0 & \text{val} - 1 & \text{nocc} - 1, \\
\text{column} - 0 & \text{val} - 2 & \text{nocc} - 0, \\
\text{column} - 0 & \text{val} - 3 & \text{nocc} - 2, \\
\text{column} - 0 & \text{val} - 4 & \text{nocc} - 0, \\
\text{column} - 1 & \text{val} - 0 & \text{nocc} - 0, \\
\text{column} - 1 & \text{val} - 1 & \text{nocc} - 0, \\
\text{column} - 1 & \text{val} - 2 & \text{nocc} - 0, \\
\text{column} - 1 & \text{val} - 3 & \text{nocc} - 1, \\
\text{column} - 1 & \text{val} - 4 & \text{nocc} - 2 \\
\end{pmatrix},
\begin{pmatrix}
\text{line} - 0 & \text{val} - 0 & \text{nocc} - 0, \\
\text{line} - 0 & \text{val} - 1 & \text{nocc} - 0, \\
\text{line} - 0 & \text{val} - 2 & \text{nocc} - 0, \\
\text{line} - 0 & \text{val} - 3 & \text{nocc} - 1, \\
\text{line} - 0 & \text{val} - 4 & \text{nocc} - 1, \\
\text{line} - 1 & \text{val} - 0 & \text{nocc} - 0, \\
\text{line} - 1 & \text{val} - 1 & \text{nocc} - 0, \\
\text{line} - 1 & \text{val} - 2 & \text{nocc} - 0, \\
\text{line} - 1 & \text{val} - 3 & \text{nocc} - 1, \\
\text{line} - 1 & \text{val} - 4 & \text{nocc} - 1 \\
\end{pmatrix}
\]

Typical

\[
C \geq 1, \\
L \geq 1, \\
K \geq 1
\]

\[\text{range}(\text{MATRIX.var}) > 1\]

Arg. properties

- Functional dependency: \text{CPRJ.nocc} determined by \text{C}, \text{L} and \text{K}.
- Functional dependency: \text{LPRJ.nocc} determined by \text{C}, \text{L} and \text{K}.

Remark

Within [361] the \text{COLORED\_MATRIX} constraint is called \text{CARDINALITY\_MATRIX}.

Algorithm

The filtering algorithm described in [361] is based on network flow and does not achieve arc-consistency in general. However, when the number of values is restricted to two, the algorithm [361] achieves arc-consistency on the variables of the matrix. This corresponds in fact to a generalisation of the problem called "Matrices composed of 0's and 1's" presented by Ford and Fulkerson [238].

COLOURED_CUMULATIVE

Figure 5.199: The coloured cumulative solution to the Example slot with at most two distinct colours in parallel

Symmetries

- Items of TASKS are permutable.
- One and the same constant can be added to the origin and end attributes of all items of TASKS.
- All occurrences of two distinct values of TASKS.colour can be swapped; all occurrences of a value of TASKS.colour can be renamed to any unused value.
- LIMIT can be increased.

Arg. properties

Contractible wrt. TASKS.

Usage

Useful for scheduling problems where a machine can only proceed in parallel a maximum number of tasks of distinct type. This condition cannot be modelled by the classical CUMULATIVE constraint. Also useful for coloured bin packing problems (i.e., duration = 1) where each item has a colour and no bin contains items with more than LIMIT distinct colours [141, 197, 217].

Reformulation

The COLOURED_CUMULATIVE constraint can be expressed in term of a set of reified constraints and of [TASKS] NVALUE constraints:

1. For each pair of tasks TASKS[i], TASKS[j] \(i, j \in [1, |\text{TASKS}|]\) of the TASKS collection we create a variable \(C_{ij}\) which is set to the colour of task TASKS[j] if task TASKS[j] overlaps the origin attribute of task TASKS[i], and to the colour of task TASKS[i] otherwise:
   - If \(i = j\):
     - \(C_{ij} = \text{TASKS}[i].\text{colour}\).
   - If \(i \neq j\):
     - \(C_{ij} = \text{TASKS}[i].\text{colour} \lor C_{ij} = \text{TASKS}[j].\text{colour}\).
     - \((\text{TASKS}[j].\text{origin} \leq \text{TASKS}[i].\text{origin} \land \text{TASKS}[j].\text{end} > \text{TASKS}[i].\text{origin}) \lor (C_{ij} = \text{TASKS}[j].\text{colour})\) \lor 
     - \((\text{TASKS}[j].\text{origin} > \text{TASKS}[i].\text{origin} \lor \text{TASKS}[j].\text{end} \leq \text{TASKS}[i].\text{origin}) \land (C_{ij} = \text{TASKS}[i].\text{colour})\)
2. For each task \( \text{TASKS}[i] \) \((i \in [1, |\text{TASKS}|])\) we create a variable \( N_i \) which gives the number of distinct colours associated with the tasks that overlap the origin of task \( \text{TASKS}[i] \) (\( \text{TASKS}[i] \) overlaps its own origin) and we impose \( N_i \) to not exceed the maximum number of distinct colours \( \text{LIMIT} \) allowed at each instant:

- \( N_i \geq 1 \land N_i \leq \text{LIMIT} \).
- \( \text{NVALUE}(N_i, (C_{i1}, C_{i2}, \ldots, C_{i|\text{TASKS}|})) \).

| Constraint(s) on sets | $\text{NVALUES}(\text{variables}, \leq, \text{LIMIT})$ |

#### Graph model
Same as CUMULATIVE, except that we use another constraint for computing the resource consumption at each time point.

Parts (A) and (B) of Figure 5.200 respectively show the initial and final graph associated with the second graph constraint of the Example slot. On the one hand, each source vertex of the final graph can be interpreted as a time point. On the other hand the successors of a source vertex correspond to those tasks that overlap that time point. The COLOURED_CUMULATIVE constraint holds since for each successor set $S$ of the final graph the number of distinct colours of the tasks in $S$ does not exceed the LIMIT 2.

#### Signature
Since TASKS is the maximum number of vertices of the final graph of the first graph constraint we can rewrite $NARC = |\text{TASKS}|$ to $NARC \geq |\text{TASKS}|$. This leads to simplify $NARC$ to $NARC$. 

---
Figure 5.200: Initial and final graph of the COLOURED_CUMULATIVE constraint
5.76 COLOURED_CUMULATIVES

Description

Origin

Derived from CUMULATIVES and NVALUES.

Constraint

COLOURED_CUMULATIVES(TASKS, MACHINES)

Synonym

COLORED_CUMULATIVES.

Arguments

TASKS : collection(machine−dvar, origin−dvar, duration−dvar, end−dvar, colour−dvar)

MACHINES : collection(id−int, capacity−int)

Restrictions

required(TASKS,[machine,colour])
require_at_least(2,TASKS,[origin,duration,end])
TASKS.duration ≥ 0
TASKS.origin ≤ TASKS.end
required(MACHINES,[id,capacity])
distinct(MACHINES,id)
MACHINES.capacity ≥ 0

Purpose

Consider a set $\mathcal{T}$ of tasks described by the TASKS collection. The COLOURED_CUMULATIVES constraint forces for each machine $m$ of the MACHINES collection the following condition: at each point in time $p$, the numbers of distinct colours of the set of tasks that both overlap that point $p$ and are assigned to machine $m$ does not exceed the capacity of machine $m$. A task overlaps a point $i$ if and only if (1) its origin is less than or equal to $i$, and (2) its end is strictly greater than $i$. It also imposes for each task of $\mathcal{T}$ the constraint $\text{origin} + \text{duration} = \text{end}$.

Example

Consider a set $\mathcal{T}$ of tasks described by the TASKS collection. The COLOURED_CUMULATIVES constraint forces for each machine $m$ of the MACHINES collection the following condition: at each point in time $p$, the numbers of distinct colours of the set of tasks that both overlap that point $p$ and are assigned to machine $m$ does not exceed the capacity of machine $m$. A task overlaps a point $i$ if and only if (1) its origin is less than or equal to $i$, and (2) its end is strictly greater than $i$. It also imposes for each task of $\mathcal{T}$ the constraint $\text{origin} + \text{duration} = \text{end}$.

Figure 5.201 shows the solution associated with the example. Each rectangle of the figure corresponds to a task of the COLOURED_CUMULATIVES constraint. Tasks that have their colour attributes set to 1 and 2 are respectively coloured in blue and pink. The COLOURED_CUMULATIVES constraint holds since for machine 1 we have at most...
two distinct colours in parallel (which is the maximum capacity for machine 1), while for machine 2 we have no more than a single colour in parallel (which is actually the maximum capacity for machine 2).

Figure 5.201: The coloured cumulative solution to the Example slot with at most two distinct colours in parallel on machine 1 and at most one distinct colour in parallel on machine 2.
Symmetries

- Items of TASKS are permutable.
- Items of MACHINES are permutable.
- MACHINES.m_capacity can be increased.
- All occurrences of two distinct values in TASKS.machine or MACHINES.id can be swapped; all occurrences of a value in TASKS.machine or MACHINES.id can be renamed to any unused value.

Arg. properties

Contractible wrt. TASKS.

Usage

Useful for scheduling problems where several machines are available and where you have to assign each task to a specific machine. In addition each machine can only proceed in parallel a maximum number of tasks of distinct types.

Reformulation

The COLOURED_CUMULATIVES constraint can be expressed in term of a set of reified constraints and of |TASKS| NVALUE constraints:

1. For each pair of tasks TASKS[i], TASKS[j] (i, j ∈ [1, |TASKS|]) of the TASKS collection we create a variable C_{ij} which is set to the colour of task TASKS[j] if both tasks are assigned to the same machine and if task TASKS[j] overlaps the origin attribute of task TASKS[i], and to the colour of task TASKS[j] otherwise:
   - If i = j:
     - C_{ij} = TASKS[i].colour.
   - If i ≠ j:
     - C_{ij} = TASKS[i].colour ∨ C_{ij} = TASKS[j].colour.
     - ((TASKS[j].machine = TASKS[i].machine ∧ TASKS[j].origin ≤ TASKS[i].origin ∧ TASKS[j].end > TASKS[i].origin) ∨ (C_{ij} = TASKS[j].colour)) ∨
     - ((TASKS[j].machine ≠ TASKS[i].machine ∨ TASKS[j].origin > TASKS[i].origin ∨ TASKS[j].end ≤ TASKS[i].origin) ∧ (C_{ij} = TASKS[i].colour))

2. For each task TASKS[i] (i ∈ [1, |TASKS|]) we create a variable N_i, which gives the number of distinct colours associated with the tasks that both are assigned to the same machine as task TASKS[i] and overlap the origin of task TASKS[i] (TASKS[i] overlaps its own origin) and we impose N_i to not exceed the maximum number of distinct colours LIMIT allowed at each instant:
   - N_i ≥ 1 ∧ N_i ≤ LIMIT.
   - NVALUE(N_i, (C_{i1}, C_{i2}, ..., C_{|TASKS|})).

See also

&\text{variables} - \text{col} \left( \text{VARIABLES} - \text{collection}(\text{var} - \text{dvar}), \\
&\text{item}(\text{var} - \text{TASKS}.\text{colour}) \right) \end{align*} \)
Constraint(s) on sets | \( \text{NVALUES} (\text{variables}, \leq, \text{MACHINES}.\text{capacity}) \)

Graph model

Parts (A) and (B) of Figure 5.202 respectively shows the initial and final graph associated with machines 1 and 2 involved in the Example slot. On the one hand, each source vertex of the final graph can be interpreted as a time point \( p \) on a specific machine \( m \). On the other hand the successors of a source vertex correspond to those tasks that both overlap that time point \( p \) and are assigned to machine \( m \). The COLOURED_CUMULATIVES constraint holds since for each successor set \( S \) of the final graph the number of distinct colours in \( S \) does not exceed the capacity of the machine corresponding to the time point associated with \( S \).

Signature

Since TASKS is the maximum number of vertices of the final graph of the first graph constraint we can rewrite \( \text{NARC} = |\text{TASKS}| \) to \( \text{NARC} \geq |\text{TASKS}| \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).
Figure 5.202: Initial and final graph of the \texttt{COLOURED\_CUMULATIVES} constraint
5.77 COMMON

Description

Origin
N. Beldiceanu

Constraint

\[ \text{COMMON}(\text{NCOMMON1}, \text{NCOMMON2}, \text{VARIABLES1}, \text{VARIABLES2}) \]

Arguments

\begin{align*}
\text{NCOMMON1} & : \text{dvar} \\
\text{NCOMMON2} & : \text{dvar} \\
\text{VARIABLES1} & : \text{collection(var-dvar)} \\
\text{VARIABLES2} & : \text{collection(var-dvar)}
\end{align*}

Restrictions

\begin{align*}
\text{NCOMMON1} & \geq 0 \\
\text{NCOMMON1} & \leq |\text{VARIABLES1}| \\
\text{NCOMMON2} & \geq 0 \\
\text{NCOMMON2} & \leq |\text{VARIABLES2}| \\
\text{required}\!(\text{VARIABLES1}, \text{var}) \\
\text{required}\!(\text{VARIABLES2}, \text{var})
\end{align*}

Purpose

- \text{NCOMMON1} is the number of variables of the collection of variables \text{VARIABLES1} taking a value in \text{VARIABLES2}.
- \text{NCOMMON2} is the number of variables of the collection of variables \text{VARIABLES2} taking a value in \text{VARIABLES1}.

Example

\begin{align*}
(3, \langle 1, 9, 1, 5 \rangle, \langle 2, 1, 9, 9, 6, 9 \rangle)
\end{align*}

The \text{COMMON} constraint holds since:

- Its first argument \text{NCOMMON1} = 3 corresponds to the number of values of the collection \langle 1, 9, 1, 5 \rangle that occur within \langle 2, 1, 9, 9, 6, 9 \rangle.
- Its second argument \text{NCOMMON2} = 4 corresponds to the number of values of the collection \langle 2, 1, 9, 9, 6, 9 \rangle that occur within \langle 1, 9, 1, 5 \rangle.

All solutions

Figure 5.203 gives all solutions to the following non ground instance of the \text{COMMON} constraint:

\[ \text{NCOMMON1} \in [0, 1], \text{NCOMMON2} \in [2, 3], \text{U}_1 \in [1, 2], \text{U}_2 \in [1, 2], \text{U}_3 \in [0, 1], \text{U}_4 \in [5, 6], \text{V}_1 \in [5, 6], \text{V}_2 \in [1, 2], \text{V}_3 \in [0, 1], \text{COMMON}(\text{NCOMMON1}, \text{NCOMMON2}, \langle \text{U}_1, \text{U}_2, \text{U}_3, \text{U}_4 \rangle, \langle \text{V}_1, \text{V}_2, \text{V}_3 \rangle). \]

Typical

\begin{align*}
|\text{VARIABLES1}| & > 1 \\
\text{range}\!(\text{VARIABLES1}.\text{var}) & > 1 \\
|\text{VARIABLES2}| & > 1 \\
\text{range}\!(\text{VARIABLES2}.\text{var}) & > 1
\end{align*}
Figure 5.203: All solutions corresponding to the non ground example of the COMMON constraint of the All solutions slot

Symmetries

- Arguments are permutable w.r.t. permutation \((N\text{COMMON1}, N\text{COMMON2})\) \((\text{VARIABLES1, VARIABLES2})\).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Arg. properties

- Functional dependency: NCOMMON1 determined by VARIABLES1 and VARIABLES2.
- Functional dependency: NCOMMON2 determined by VARIABLES1 and VARIABLES2.

Remark

It was shown in [76] that, finding out whether the COMMON constraint has a solution or not is NP-hard. This was achieved by reduction from 3-SAT.

See also

- common keyword: ALLDIFFERENT_ON_INTERSECTION, NVALUE_ON_INTERSECTION, SAME_INTERSECTION (constraint on the intersection).
- generalisation: COMMON_INTERVAL (variable replaced by variable/constant), COMMON_MODULO (variable replaced by variable \(\mod\) constant), COMMON_PARTITION (variable replaced by variable \(\in\) partition).
- related: AMONG_VAR, ROOTS.
- root concept: AMONG.
- specialisation: USES \((N\text{COMMON2}=|\text{VARIABLES2}|)\).

Keywords

- complexity: 3-SAT.
- constraint arguments: constraint between two collections of variables, pure functional dependency.
- constraint type: constraint on the intersection.
- final graph structure: acyclic, bipartite, no loop.
Graph model

Parts (A) and (B) of Figure 5.204 respectively show the initial and final graph associated with the Example slot. Since we use the NSOURCE and NSINK graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since the final graph has only 3 sources and 4 sinks the variables NCOMMON1 and NCOMMON2 are respectively equal to 3 and 4. Note that all the vertices corresponding to the variables that take values 5, 2 or 6 were removed from the final graph since there is no arc for which the associated equality constraint holds.

Figure 5.204: Initial and final graph of the COMMON constraint
5.78 COMMON_INTERVAL

Origin
Derived from COMMON.

Constraint

\[
\text{COMMON\_INTERVAL (NCOMMON1, NCOMMON2, VARIABLES1, VARIABLES2, SIZE\_INTERVAL)}
\]

Arguments
- \(NCOMMON1\) : dvar
- \(NCOMMON2\) : dvar
- \(VARIABLES1\) : collection(var\−dvar)
- \(VARIABLES2\) : collection(var\−dvar)
- \(SIZE\_INTERVAL\) : int

Restrictions
- \(NCOMMON1 \geq 0\)
- \(NCOMMON1 \leq |VARIABLES1|\)
- \(NCOMMON2 \geq 0\)
- \(NCOMMON2 \leq |VARIABLES2|\)
- \(\text{required}(VARIABLES1, var)\)
- \(\text{required}(VARIABLES2, var)\)
- \(SIZE\_INTERVAL > 0\)

Purpose
\(NCOMMON1\) is the number of variables of the collection of variables \(VARIABLES1\) taking a value in one of the intervals derived from the values assigned to the variables of the collection \(VARIABLES2\): To each value \(v\) assigned to a variable of the collection \(VARIABLES2\) we associate the interval \([\text{SIZE\_INTERVAL} \cdot \lfloor v/\text{SIZE\_INTERVAL} \rfloor, \text{SIZE\_INTERVAL} \cdot \lfloor v/\text{SIZE\_INTERVAL} \rfloor + \text{SIZE\_INTERVAL} - 1]\).

\(NCOMMON2\) is the number of variables of the collection of variables \(VARIABLES2\) taking a value in one of the intervals derived from the values assigned to the variables of the collection \(VARIABLES1\): To each value \(v\) assigned to a variable of the collection \(VARIABLES1\) we associate the interval \([\text{SIZE\_INTERVAL} \cdot \lfloor v/\text{SIZE\_INTERVAL} \rfloor, \text{SIZE\_INTERVAL} \cdot \lfloor v/\text{SIZE\_INTERVAL} \rfloor + \text{SIZE\_INTERVAL} - 1]\).

Example
\((3, 2, \langle 8, 6, 6, 0 \rangle, \langle 7, 3, 3, 3, 3, 7 \rangle, 3)\)

In the example, the last argument \(\text{SIZE\_INTERVAL} = 3\) defines the following family of intervals \([3 \cdot k, 3 \cdot k + 2]\), where \(k\) is an integer. As a consequence the items of collection \((8, 6, 6, 0)\) respectively correspond to intervals \([6, 8]\), \([6, 8]\), \([6, 8]\) and \([0, 2]\). Similarly the items of collection \((7, 3, 3, 3, 3, 7)\) respectively correspond to intervals \([6, 8]\), \([3, 5]\), \([3, 5]\), \([3, 5]\), \([3, 5]\), \([6, 8]\). The COMMON\_INTERVAL constraint holds since:

- Its first argument \(NCOMMON1 = 3\) is the number of intervals associated with the items of collection \((8, 6, 6, 0)\) that also correspond to intervals associated with \((7, 3, 3, 3, 3, 7)\).
Its second argument $\text{NCOMMON2} = 2$ is the number of intervals associated with the items of collection $\langle 7, 3, 3, 3, 3, 7 \rangle$ that also correspond to intervals associated with $\langle 8, 6, 6, 0 \rangle$.

Typical

- $|\text{VARIABLES1}| > 1$
- $\text{range}(\text{VARIABLES1}.\text{var}) > 1$
- $|\text{VARIABLES2}| > 1$
- $\text{range}(\text{VARIABLES2}.\text{var}) > 1$
- $\text{SIZE_INTERVAL} > 1$
- $\text{SIZE_INTERVAL} < \text{range}(\text{VARIABLES1}.\text{var})$
- $\text{SIZE_INTERVAL} < \text{range}(\text{VARIABLES2}.\text{var})$

Symmetries

- Arguments are permutable w.r.t. permutation $(\text{NCOMMON1}, \text{NCOMMON2}) (\text{VARIABLES1}, \text{VARIABLES2}) (\text{SIZE_INTERVAL})$.
- Items of $\text{VARIABLES1}$ are permutable.
- Items of $\text{VARIABLES2}$ are permutable.
- An occurrence of a value of $\text{VARIABLES1}.\text{var}$ that belongs to the $k$-th interval, of size $\text{SIZE_INTERVAL}$, can be replaced by any other value of the same interval.
- An occurrence of a value of $\text{VARIABLES2}.\text{var}$ that belongs to the $k$-th interval, of size $\text{SIZE_INTERVAL}$, can be replaced by any other value of the same interval.

Arg. properties

- Functional dependency: $\text{NCOMMON1}$ determined by $\text{VARIABLES1}$, $\text{VARIABLES2}$ and $\text{SIZE_INTERVAL}$.
- Functional dependency: $\text{NCOMMON2}$ determined by $\text{VARIABLES1}$, $\text{VARIABLES2}$ and $\text{SIZE_INTERVAL}$.

See also

specialisation: $\text{COMMON}(\text{variable}/\text{constant replaced by variable})$.

Keywords

- constraint arguments: constraint between two collections of variables, pure functional dependency.

\end{align*} \)

Figure 5.205: Initial and final graph of the \text{COMMON}_\text{INTERVAL} constraint
5.79 COMMON_MODULO

Origin
Derived from COMMON.

Constraint
`COMMON_MODULO(NCOMMON1, NCOMMON2, VARIABLES1, VARIABLES2, M)`

Arguments
- `NCOMMON1` : `dvar`
- `NCOMMON2` : `dvar`
- `VARIABLES1` : `collection(var−dvar)`
- `VARIABLES2` : `collection(var−dvar)`
- `M` : `int`

Restrictions
- `NCOMMON1 ≥ 0`
- `NCOMMON1 ≤ |VARIABLES1|`
- `NCOMMON2 ≥ 0`
- `NCOMMON2 ≤ |VARIABLES2|`
- `required(VARIABLES1, var)`
- `required(VARIABLES2, var)`
- `M > 0`

Purpose
- `NCOMMON1` is the number of variables of the collection of variables `VARIABLES1` taking a value situated in an equivalence class (congruence modulo a fixed number `M`) derived from the values assigned to the variables of `VARIABLES2` and from `M`.
- `NCOMMON2` is the number of variables of the collection of variables `VARIABLES2` taking a value situated in an equivalence class (congruence modulo a fixed number `M`) derived from the values assigned to the variables of `VARIABLES1` and from `M`.

Example
`((3, 4, 0, 4, 0, 8), (7, 5, 4, 9, 2, 4), 5)`

In the example, the last argument `M = 5` defines the equivalence classes `a ≡ 0 (mod 5)`, `a ≡ 1 (mod 5)`, `a ≡ 2 (mod 5)`, `a ≡ 3 (mod 5)`, and `a ≡ 4 (mod 5)` where `a` is an integer. As a consequence the items of collection `(0, 4, 0, 8)` respectively correspond to the equivalence classes `a ≡ 0 (mod 5)`, `a ≡ 4 (mod 5)`, `a ≡ 0 (mod 5)`, and `a ≡ 3 (mod 5)`. Similarly the items of collection `(7, 5, 4, 9, 2, 4)` respectively correspond to the equivalence classes `a ≡ 2 (mod 5)`, `a ≡ 0 (mod 5)`, `a ≡ 4 (mod 5)`, `a ≡ 4 (mod 5)`, `a ≡ 2 (mod 5)`, and `a ≡ 4 (mod 5)`. The `COMMON_MODULO` constraint holds since:

- Its first argument `NCOMMON1 = 3` is the number of equivalence classes associated with the items of collection `(0, 4, 0, 8)` that also correspond to equivalence classes associated with `(7, 5, 4, 9, 2, 4)`.
- Its second argument `NCOMMON2 = 4` is the number of equivalence classes associated with the items of collection `(7, 5, 4, 9, 2, 4)` that also correspond to equivalence classes associated with `(0, 4, 0, 8)`.
Typical

| VARIABLES1 | > 1
| range(VARIABLES1.var) | > 1
| VARIABLES2 | > 1
| range(VARIABLES2.var) | > 1
| M | > 1
| M < maxval(VARIABLES1.var)
| M < maxval(VARIABLES2.var)

Symmetries

- Arguments are permutable w.r.t. permutation \((NCOMMON1, NCOMMON2) (VARIABLES1, VARIABLES2) (M)\).
- Items of VARIABLES1 are permutable.
- Items of VARIABLES2 are permutable.
- An occurrence of a value \(u\) of VARIABLES1.var can be replaced by any other value \(v\) such that \(v\) is congruent to \(u\) modulo \(M\).
- An occurrence of a value \(u\) of VARIABLES2.var can be replaced by any other value \(v\) such that \(v\) is congruent to \(u\) modulo \(M\).

Arg. properties

- Functional dependency: \(NCOMMON1\) determined by \(VARIABLES1, VARIABLES2\) and \(M\).
- Functional dependency: \(NCOMMON2\) determined by \(VARIABLES1, VARIABLES2\) and \(M\).

See also

specialisation: COMMON (variable mod constant replaced by variable).

Keywords

characteristic of a constraint: modulo.
constraint arguments: constraint between two collections of variables, pure functional dependency.
final graph structure: acyclic, bipartite, no loop.
modelling: functional dependency.
Graph model

Parts (A) and (B) of Figure 5.206 respectively show the initial and final graph associated with the Example slot. Since we use the NSOURCE and NSINK graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since the graph has only 3 sources and 4 sinks the variables NCOMMON1 and NCOMMON2 are respectively equal to 3 and 4. Note that the vertices corresponding to the variables that take values 8, 7 or 2 were removed from the final graph since there is no arc for which the associated arc constraint holds.

Figure 5.206: Initial and final graph of the COMMON_MODULO constraint
5.80 COMMON_PARTITION

Origin
Derived from COMMON.

Constraint
COMMON_PARTITION
\[
\begin{pmatrix}
NCOMMON1, \\
NCOMMON2, \\
VARIABLES1, \\
VARIABLES2, \\
PARTITIONS
\end{pmatrix}
\]

Type
VALUES : collection(val=int)

Arguments
NCOMMON1 : dvar
NCOMMON2 : dvar
VARIABLES1 : collection(var=dvar)
VARIABLES2 : collection(var=dvar)
PARTITIONS : collection(p VALUES)

Restrictions
\mid VALUES \mid \geq 1
required(VALUE, val)
distinct(VALUE, val)
NCOMMON1 \geq 0
NCOMMON1 \leq \mid VARIABLES1 \mid
NCOMMON2 \geq 0
NCOMMON2 \leq \mid VARIABLES2 \mid
required(VARIABLES1, var)
required(VARIABLES2, var)
required(PARTITIONS, p)
\mid PARTITIONS \mid \geq 2

Purpose
NCOMMON1 is the number of variables of the VARIABLES1 collection taking a value in a partition derived from the values assigned to the variables of VARIABLES2 and from PARTITIONS.

NCOMMON2 is the number of variables of the VARIABLES2 collection taking a value in a partition derived from the values assigned to the variables of VARIABLES1 and from PARTITIONS.

Example
\[
\begin{pmatrix}
3, 4, \langle 2, 3, 6, 0 \rangle, \\
0, 6, 3, 3, 7, 1, \\
\langle p \rightarrow (1, 3), p \rightarrow (4), p \rightarrow (2, 6) \rangle
\end{pmatrix}
\]

In the example, the last argument PARTITIONS defines the partitions \( p \rightarrow (1, 3), p \rightarrow (4) \) and \( p \rightarrow (2, 6) \). As a consequence the first three items of collection \( \langle 2, 3, 6, 0 \rangle \) respectively correspond to the partitions \( p \rightarrow (2, 6), p \rightarrow (1, 3), \) and \( p \rightarrow (2, 6) \). Similarly
the items of collection $\langle 0, 6, 3, 3, 7, 1 \rangle$ (from which we remove items 0 and 7 since they do not belong to any partition) respectively correspond to the partitions $p = \langle 2, 6 \rangle$, $p = \langle 1, 3 \rangle$, $p = \langle 1, 3 \rangle$, and $p = \langle 1, 3 \rangle$. The COMMON_PARTITION constraint holds since:

- Its first argument $NCOMMON_1 = 3$ is the number of partitions associated with the items of collection $\langle 2, 3, 6, 0 \rangle$ that also correspond to partitions associated with $\langle 0, 6, 3, 3, 7, 1 \rangle$.
- Its second argument $NCOMMON_2 = 4$ is the number of partitions associated with the items of collection $\langle 0, 6, 3, 3, 7, 1 \rangle$ that also correspond to partitions associated with $\langle 2, 3, 6, 0 \rangle$.

**Typical**

\[
\begin{align*}
|VARIBL\_E1| & > 1 \\
range(VARIBL\_E1.\ivar) & > 1 \\
|VARIBL\_E2| & > 1 \\
range(VARIBL\_E2.\ivar) & > 1 \\
|VARIBL\_E1| & > |PARTITIONS| \\
|VARIBL\_E2| & > |PARTITIONS|
\end{align*}
\]

**Symmetries**

- Arguments are permutable w.r.t. permutation $(NCOMMON_1, NCOMMON_2, (VARIBL\_E1, VARIBL\_E2, (PARTITIONS))$.
- Items of $VARIBL\_E1$ are permutable.
- Items of $VARIBL\_E2$ are permutable.
- Items of $PARTITIONS$ are permutable.
- Items of $PARTITIONS.p$ are permutable.
- An occurrence of a value of $VARIBL\_E1.\ivar$ can be replaced by any other value that also belongs to the same partition of $PARTITIONS$.
- An occurrence of a value of $VARIBL\_E2.\ivar$ can be replaced by any other value that also belongs to the same partition of $PARTITIONS$.

**Arg. properties**

- Functional dependency: $NCOMMON_1$ determined by $VARIBL\_E1$, $VARIBL\_E2$ and $PARTITIONS$.
- Functional dependency: $NCOMMON_2$ determined by $VARIBL\_E1$, $VARIBL\_E2$ and $PARTITIONS$.

**See also**

specialisation: COMMON($variable \in partition replaced by variable$).

used in graph description: IN\_SAME\_PARTITION.

**Keywords**

characteristic of a constraint: partition.

constraint arguments: constraint between two collections of variables, pure functional dependency.

final graph structure: acyclic, bipartite, no loop.

modelling: functional dependency.
Arc input(s) | VARIABLES1 VARIABLES2
---|---
Arc generator | PRODUCT ↦ collection(variables1,variables2)
Arc arity | 2
Arc constraint(s) | INSAME_PARTITION(variables1.var,variables2.var,PARTITIONS)
Graph property(ies) | • NSOURCE = NCOMMON1
• NSINK = NCOMMON2
Graph class | • ACYCLIC
• BIPARTITE
• NO LOOP

Graph model

Parts (A) and (B) of Figure 5.207 respectively show the initial and final graph associated with the Example slot. Since we use the NSOURCE and NSINK graph properties, the source and sink vertices of the final graph are stressed with a double circle. Since the graph has only 3 sources and 4 sinks the variables NCOMMON1 and NCOMMON2 are respectively equal to 3 and 4. Note that the vertices corresponding to the variables that take values 0 or 7 were removed from the final graph since there is no arc for which the associated INSAME_PARTITION constraint holds.

![Graph Model](image.png)

Figure 5.207: Initial and final graph of the COMMON_PARTITION constraint
5.81 COMPARE_AND_COUNT

**Origin** Generalise DISCREPANCY

**Constraint** COMPARE_AND_COUNT(VARIABLES1, VARIABLES2, COMPARE, COUNT, LIMIT)

**Arguments**
- VARIABLES1 : collection(var−dvar)
- VARIABLES2 : collection(var−dvar)
- COMPARE : atom
- COUNT : atom
- LIMIT : dvar

**Restrictions**
- \(|\text{VARIABLES1}| = |\text{VARIABLES2}|\)
- required(VARIABLES1, var)
- required(VARIABLES2, var)
- COMPARE ∈ [\(=, \neq, <, \geq, >, \leq\)]
- COUNT ∈ [\(=, \neq, <, \geq, >, \leq\)]
- LIMIT ≥ 0

**Purpose** Enforce the condition \(\left(\sum_{i=1}^{|\text{VARIABLES1}|} \text{VARIABLES1}[i].\text{var} \text{COMPARE} \text{VARIABLES2}[i].\text{var}\right) \text{COUNT} \text{LIMIT}.\)

**Example** \((\langle 4, 5, 4, 5 \rangle, \langle 4, 2, 5, 1, 5 \rangle, =, \leq, 3)\)

The COMPARE_AND_COUNT constraint holds since no more than \(\text{LIMIT} = 3\) pairs of variables are equal, i.e., the first, third and fifth pairs.

**Typical**
- \(|\text{VARIABLES1}| > 1\)
- range(VARIABLES1, var) > 1
- range(VARIABLES2, var) > 1
- COMPARE ∈ [\(=\)]
- COUNT ∈ [\(=, <, \geq, >, \leq\)]
- LIMIT > 0
- LIMIT < |VARIABLES1|

**Arg. properties**
- **Contractible** wrt. VARIABLES1 and VARIABLES2 (remove items from same position) when COUNT ∈ [\(<, \leq\)].
- **Extensible** wrt. VARIABLES1 and VARIABLES2 (add items at same position) when COUNT ∈ [\(\geq, >\)].

**See also** common keyword: COUNT (counting constraint).

**Keywords** constraint type: predefined constraint, counting constraint.
5.82  COND_LEX_COST

Origin
Inspired by [448].

Constraint
COND_LEX_COST(VECTOR, PREFERENCE_TABLE, COST)

Type
TUPLE_OF_VALS : \text{collection}(val\rightarrow\text{int})

Arguments
VECTOR : \text{collection}(var\rightarrow\text{dvar})
PREFERENCE_TABLE : \text{collection}(\text{tuple} \rightarrow \text{TUPLE_OF_VALS})
COST : \text{dvar}

Restrictions
\[|\text{TUPLE_OF_VALS}| \geq 1\]
\[\text{required}(\text{TUPLE_OF_VALS}, \text{val})\]
\[\text{required}(\text{VECTOR}, \text{var})\]
\[|\text{VECTOR}| = |\text{TUPLE_OF_VALS}|\]
\[\text{required}(\text{PREFERENCE_TABLE}, \text{tuple})\]
\[\text{same_size}(\text{PREFERENCE_TABLE}, \text{tuple})\]
\[\text{distinct}(\text{PREFERENCE_TABLE}, [])\]
\[\text{IN_RELATION}(\text{VECTOR}, \text{PREFERENCE_TABLE})\]
\[\text{COST} \geq 1\]
\[\text{COST} \leq |\text{PREFERENCE_TABLE}|\]

Purpose
VECTOR is assigned to the COST\textsuperscript{th} item of the collection PREFERENCE_TABLE.

Example
\[
\left\langle \langle 0,1 \rangle, \\
\langle \text{tuple} = (1,0), \\
\langle \text{tuple} = (0,1), \\
\langle \text{tuple} = (0,0), \\
\text{tuple} = (1,1) \rangle \right\rangle
\]

The COND_LEX_COST constraint holds since VECTOR is assigned to the second item of the collection PREFERENCE_TABLE.

Typical
\[|\text{TUPLE_OF_VALS}| > 1\]
\[|\text{VECTOR}| > 1\]
\[|\text{PREFERENCE_TABLE}| > 1\]

Symmetries
- Items of VECTOR and PREFERENCE_TABLE.tuple are permutable (same permutation used).
- All occurrences of two distinct tuples of values in VECTOR or PREFERENCE_TABLE.tuple can be swapped; all occurrences of a tuple of values in VECTOR or PREFERENCE_TABLE.tuple can be renamed to any unused tuple of values.
We consider an example taken from [448] were a customer has to decide among vacations. There are two seasons when he can travel (spring and summer) and two locations Naples and Helsinki. Furthermore assume that location is more important than season and the preferred period of the year depends on the selected location. The travel preferences of a customer are explicitly defined by stating the preferences ordering among the possible tuples of values \(<\text{Naples, spring}\rangle, \langle\text{Naples, summer}\rangle, \langle\text{Helsinki, spring}\rangle\) and \(<\text{Helsinki, summer}\rangle\). For instance we may state within the preference table PREFERENCE\_TABLE of the COND\_LEX\_COST constraint the preference ordering \(<\text{Naples, spring}\rangle \succ \langle\text{Helsinki, summer}\rangle \succ \langle\text{Helsinki, spring}\rangle \succ \langle\text{Naples, summer}\rangle\), which denotes the fact that our customer prefers Naples in the spring and Helsinki in the summer, and a vacation in spring is preferred over summer. Finally a solution minimising the cost variable COST will match the preferences stated by our customer.

5.83 COND_LEX_GREATER

**Description**

Inspired by [448].

**Constraint**

\[
\text{COND\_LEX\_GREATER}(\text{VECTOR1}, \text{VECTOR2}, \text{PREFERENCE\_TABLE})
\]

**Type**

\[
\text{TUPLE\_OF\_VALS} : \text{collection(val-int)}
\]

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>VECTOR1</td>
<td>\text{collection(var-dvar)}</td>
</tr>
<tr>
<td>VECTOR2</td>
<td>\text{collection(var-dvar)}</td>
</tr>
<tr>
<td>PREFERENCE_TABLE</td>
<td>\text{collection(tuple-TUPLE_OF_VALS)}</td>
</tr>
</tbody>
</table>

**Restrictions**

\[
\begin{align*}
|\text{TUPLE\_OF\_VALS}| & \geq 1 \\
\text{required}(\text{TUPLE\_OF\_VALS}, \text{val}) \\
\text{required}(\text{VECTOR1}, \text{var}) \\
\text{required}(\text{VECTOR2}, \text{var}) \\
|\text{VECTOR1}| & = |\text{VECTOR2}| \\
|\text{VECTOR1}| & = |\text{TUPLE\_OF\_VALS}| \\
\text{required}(\text{PREFERENCE\_TABLE}, \text{tuple}) \\
\text{same\_size}(\text{PREFERENCE\_TABLE}, \text{tuple}) \\
\text{distinct}(\text{PREFERENCE\_TABLE}, []) \\
\text{IN\_RELATION}(\text{VECTOR1}, \text{PREFERENCE\_TABLE}) \\
\text{IN\_RELATION}(\text{VECTOR2}, \text{PREFERENCE\_TABLE})
\end{align*}
\]

**Purpose**

\(\text{VECTOR1}\) and \(\text{VECTOR2}\) are both assigned to the \(I^{th}\) and \(J^ {th}\) items of the collection \(\text{PREFERENCE\_TABLE}\) such that \(I > J\).

**Example**

\[
\begin{pmatrix}
(0, 0), \\
(1, 0), \\
\text{tuple} \rightarrow (1, 0), \\
\text{tuple} \rightarrow (0, 1), \\
\text{tuple} \rightarrow (0, 0), \\
\text{tuple} \rightarrow (1, 1)
\end{pmatrix}
\]

The \text{COND\_LEX\_GREATER} constraint holds since \(\text{VECTOR1}\) and \(\text{VECTOR2}\) are respectively assigned to the third and first items of the collection \(\text{PREFERENCE\_TABLE}\).

**Typical**

\[
\begin{align*}
|\text{TUPLE\_OF\_VALS}| & > 1 \\
|\text{VECTOR1}| & > 1 \\
|\text{VECTOR2}| & > 1 \\
|\text{PREFERENCE\_TABLE}| & > 1
\end{align*}
\]
Symmetries

- Items of VECTOR1, VECTOR2 and PREFERENCE_TABLE.tuple are permutable (same permutation used).
- All occurrences of two distinct tuples of values in VECTOR1, VECTOR2 or PREFERENCE_TABLE.tuple can be swapped; all occurrences of a tuple of values in VECTOR1, VECTOR2 or PREFERENCE_TABLE.tuple can be renamed to any unused tuple of values.

Usage

### 5.84 COND_LEX_GREATEREQ

**Description**

Inspired by [448].

**Constraint**

`COND_LEX_GREATEREQ(VECTOR1, VECTOR2, PREFERENCE_TABLE)`

**Type**

| TUPLE_OF_VALS : collection(val–int) |

**Arguments**

- `VECTOR1` : `collection(var–dvar)`
- `VECTOR2` : `collection(var–dvar)`
- `PREFERENCE_TABLE` : `collection(tuple – TUPLE_OF_VALS)`

**Restrictions**

- `|TUPLE_OF_VALS| ≥ 1`
- `required(TUPLE_OF_VALS.val)`
- `required(VECTOR1.var)`
- `required(VECTOR2.var)`
- `|VECTOR1| = |VECTOR2|`
- `|VECTOR1| = |TUPLE_OF_VALS|`
- `required(PREFERENCE_TABLE.tuple)`
- `same_size(PREFERENCE_TABLE, tuple)`
- `distinct(PREFERENCE_TABLE, [])`
- `IN_RELATION(VECTOR1, PREFERENCE_TABLE)`
- `IN_RELATION(VECTOR2, PREFERENCE_TABLE)`

**Purpose**

`VECTOR1` and `VECTOR2` are both assigned to the $I^{th}$ and $J^{th}$ items of the collection `PREFERENCE_TABLE` such that $I ≥ J$.

**Example**

\[
\begin{pmatrix}
(0, 0), \\
(1, 0), \\
\text{tuple} = (1, 0), \\
\text{tuple} = (0, 1), \\
\text{tuple} = (0, 0), \\
\text{tuple} = (1, 1)
\end{pmatrix}
\]

The `COND_LEX_GREATEREQ` constraint holds since `VECTOR1` and `VECTOR2` are respectively assigned to the third and first items of the collection `PREFERENCE_TABLE`.

**Typical**

- `|TUPLE_OF_VALS| > 1`
- `|VECTOR1| > 1`
- `|VECTOR2| > 1`
- `|PREFERENCE_TABLE| > 1`
Symmetries

- Items of VECTOR1, VECTOR2 and PREFERENCE_TABLE.tuple are permutable (same permutation used).
- All occurrences of two distinct tuples of values in VECTOR1, VECTOR2 or PREFERENCE_TABLE.tuple can be swapped; all occurrences of a tuple of values in VECTOR1, VECTOR2 or PREFERENCE_TABLE.tuple can be renamed to any unused tuple of values.

See also

common keyword: COND.LEX_COST, COND.LEX_GREATER, COND.LEX_GREATEREQ, COND.LEX.LESSEQ (preferences), LEX.LESS (lexicographic order).

implies: COND.LEX.LESSEQ.

Keywords

characteristic of a constraint: vector, automaton.
constraint network structure: Berge-acyclic constraint network.
constraint type: order constraint.
filtering: arc-consistency.
modelling: preferences.
symmetry: lexicographic order.
Figure 5.214 depicts the automaton associated with the preference table of the $\text{COND}_\text{LEX}_\text{LESS}$ constraint given in the example. Let $\text{VAR}_1$ and $\text{VAR}_2$ respectively be the $\text{var}$ attributes of the $k^{th}$ items of the $\text{VECTOR}_1$ and the $\text{VECTOR}_2$ collections. Figure 5.215 depicts the reformulation of the $\text{COND}_\text{LEX}_\text{LESS}$ constraint. This reformulation uses:

- Two occurrences of the automaton depicted by Figure 5.214 for computing the positions $I$ and $J$ within the preference table corresponding to $\text{VECTOR}_1$ and $\text{VECTOR}_2$.
- The binary constraint $I < J$.

Figure 5.214: Automaton associated with the preference table of the $\text{COND}_\text{LEX}_\text{LESS}$ constraint given in the Example slot

Figure 5.215: Hypergraph of the reformulation corresponding to the $\text{COND}_\text{LEX}_\text{LESS}$ constraint: it uses two occurrences of the automaton of Figure 5.214 and the constraint $I < J$
5.86 COND_LEX_LESSEQ

Origin
Inspired by [448].

Constraint
COND_LEX_LESSEQ(VECTOR1, VECTOR2, PREFERENCE_TABLE)

Type
TUPLE_OF_VALS : collection(val=int)

Arguments
VECTOR1 : collection(var=dvar)
VECTOR2 : collection(var=dvar)
PREFERENCE_TABLE : collection(tuple=TUPLE_OF_VALS)

Restrictions
\[ |TUPLE_OF_VALS| \geq 1 \]
required(TUPLE_OF_VALS.val)
required(VECTOR1.var)
required(VECTOR2.var)
|VECTOR1| = |VECTOR2|
|VECTOR1| = |TUPLE_OF_VALS|
required(PREFERENCE_TABLE, tuple)
same_size(PREFERENCE_TABLE, tuple)
distinct(PREFERENCE_TABLE, [ ])
IN_RELATION(VECTOR1, PREFERENCE_TABLE)
IN_RELATION(VECTOR2, PREFERENCE_TABLE)

Purpose
VECTOR1 and VECTOR2 are both assigned to the Ith and Jth items of the collection PREFERENCE_TABLE such that I \leq J.

Example
\[
\left\{ \langle 1, 0 \rangle, \\
\langle 0, 0 \rangle, \\
\text{tuple - } \langle 1, 0 \rangle, \\
\text{tuple - } \langle 0, 1 \rangle, \\
\text{tuple - } \langle 0, 0 \rangle, \\
\text{tuple - } \langle 1, 1 \rangle \right\}
\]

The COND_LEX_LESSEQ constraint holds since VECTOR1 and VECTOR2 are respectively assigned to the first and third items of the collection PREFERENCE_TABLE.

Typical
\[ |TUPLE_OF_VALS| > 1 \]
|VECTOR1| > 1
|VECTOR2| > 1
|PREFERENCE_TABLE| > 1
Symmetries

- Items of VECTOR1, VECTOR2 and PREFERENCE_TABLE.tuple are permutable (same permutation used).
- All occurrences of two distinct tuples of values in VECTOR1, VECTOR2 or PREFERENCE_TABLE.tuple can be swapped; all occurrences of a tuple of values in VECTOR1, VECTOR2 or PREFERENCE_TABLE.tuple can be renamed to any unused tuple of values.

Usage

See COND.LEX.COST.

See also

common keyword: COND.LEX.COST, COND.LEX.GREATER, COND.LEX.GREATEREQ, COND.LEX.LESS (preferences), LEX.LESSEQ (lexicographic order).

symmetry: lexicographic order.
Automaton

Figure 5.216 depicts the automaton associated with the preference table of the CONDLEXLESSEQ constraint given in the example. Let VAR1k and VAR2k respectively be the var attributes of the kth items of the VECTOR1 and the VECTOR2 collections. Figure 5.217 depicts the reformulation of the CONDLEXLESSEQ constraint. This reformulation uses:

- Two occurrences of the automaton depicted by Figure 5.216 for computing the positions I and J within the preference table corresponding to VECTOR1 and VECTOR2.
- The binary constraint $I \leq J$.

5.87 CONNECT_POINTS

**Origin**  
N. Beldiceanu

**Constraint**  
CONNECT_POINTS(SIZE1, SIZE2, SIZE3, NGROUP, POINTS)

**Arguments**  
- SIZE1 : int
- SIZE2 : int
- SIZE3 : int
- NGROUP : dvar
- POINTS : collection(p-dvar)

**Restrictions**  
- SIZE1 > 0
- SIZE2 > 0
- SIZE3 > 0
- NGROUP ≥ 0
- NGROUP ≤ |POINTS|
- SIZE1 * SIZE2 * SIZE3 = |POINTS|
- required(POINTS, p)

**Purpose**  
On a 3-dimensional grid of variables, number of groups, where a group consists of a connected set of variables that all have a same value distinct from 0.
Figure 5.218 corresponds to the solution where we describe separately each layer of the grid. The CONNECT_POINTS constraint holds since we have two groups (NGROUP = 2): a first one for the variables of the POINTS collection assigned to value 1, and a second one for the variables assigned to value 2.

Figure 5.218: The two layers of the solution
**Typical**

- \( \text{SIZE1} > 1 \)
- \( \text{SIZE2} > 1 \)
- \( \text{NGROUP} > 0 \)
- \( \text{NGROUP} < |\text{POINTS}| \)
- \( |\text{POINTS}| > 3 \)

**Symmetry**

All occurrences of two distinct values of \( \text{POINTS} \) that are both different from 0 can be **swapped**; all occurrences of a value of \( \text{POINTS} \) that is different from 0 can be **renamed** to any unused value that is also different from 0.

**Arg. properties**

**Functional dependency:** \( \text{NGROUP} \) determined by \( \text{SIZE1}, \text{SIZE2}, \text{SIZE3} \) and \( \text{POINTS} \).

**Usage**

Wiring problems [393], [462].

**Algorithm**

Since the graph corresponding to the 3-dimensional grid is symmetric one could certainly use as a starting point the filtering algorithm associated with the **number of connected components** graph property described in [58] (see the paragraphs “Estimating NCC” and “Estimating NCC”). One may also try to take advantage of the fact that the considered initial graph is a grid in order to simplify the previous filtering algorithm.

**Keywords**

- **characteristic of a constraint:** joker value.
- **final graph structure:** strongly connected component, symmetric.
- **geometry:** geometrical constraint.
- **modelling:** functional dependency.
- **problems:** channel routing.
Connect_points

Arc input(s): POINTS
Arc generator: $GRID([\text{SIZE1}, \text{SIZE2}, \text{SIZE3}]) \rightarrow \text{collection}(\text{points1}, \text{points2})$
Arc arity: 2
Arc constraint(s):
  • points1.p \neq 0
  • points1.p = points2.p
Graph property(ies): NSCC = NGROUP
Graph class: SYMMETRIC

Graph model: Figure 5.219 gives the initial graph constructed by the $GRID$ arc generator associated with the Example slot.

Figure 5.219: Graph generated by $GRID ([8, 4, 2])$
5.88 CONNECTED

Description

Origin: [151]

Constraint: CONNECTED(NODES)

Argument: NODES : collection(index−int,succ−svar)

Restrictions: required(NODES,[index,succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES,index)
NODES.succ ≥ 1
NODES.succ ≤ |NODES|

Purpose

Consider a digraph $G$ described by the NODES collection. Select a subset of arcs of $G$ so that the corresponding graph is symmetric (i.e., if there is an arc from $i$ to $j$, there is also an arc from $j$ to $i$) and connected (i.e., there is a path between any pair of vertices of $G$).

Example

The CONNECTED constraint holds since the NODES collection depicts a symmetric graph involving a single connected component.

<table>
<thead>
<tr>
<th>Typical</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Symmetry</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Items of NODES are permutable.</td>
</tr>
</tbody>
</table>

Algorithm

A filtering algorithm for the CONNECTED constraint is sketched in [151, page 88]. Beside the pruning associated with the fact that the final graph is symmetric, it is based on the fact that all bridges and cut vertices on a path between two vertices that should for sure belong to the final graph should also belong to the final graph.

See also

- common keyword: SYMMETRIC (symmetric).
- implies: STRONGLY_CONNECTED.
- used in graph description: IN_SET.

Keywords

- constraint arguments: constraint involving set variables.
- constraint type: graph constraint.
- filtering: DFS-bottleneck.
- final graph structure: connected component, symmetric.
### Graph model

Part (A) of Figure 5.220 shows the initial graph from which we start. It is derived from the set associated with each vertex. Each set describes the potential values of the `succ` attribute of a given vertex. Part (B) of Figure 5.220 gives the final graph associated with the Example slot.

![Graph Diagram](image)

**Figure 5.220**: Initial and final graph of the CONNECTED set constraint
5.89 CONSECUTIVE_GROUPS_OF_ONES

DESCRIPTION

Origin
Derived from GROUP

Constraint
CONSECUTIVE_GROUPS_OF_ONES(GROUP_SIZES, VARIABLES)

Arguments
GROUP_SIZES : collection(nb=int)
VARIABLES : collection(var=dvar)

Restrictions
required(GROUP_SIZES, nb)
|GROUP_SIZES| ≥ 1
GROUP_SIZES.nb ≥ 1
GROUP_SIZES.nb ≤ |VARIABLES|
required(VARIABLES, var)
|VARIABLES| ≥ 2 * |GROUP_SIZES| − 1
|VARIABLES| ≥ sum(GROUP_SIZES.nb) + |GROUP_SIZES| − 1
VARIABLES.var ≥ 0
VARIABLES.var ≤ 1

Purpose
In order to define the meaning of the CONSECUTIVE_GROUPS_OF_ONES constraint, we first introduce the notions of stretch and span. Let n be the number of variables of the collection VARIABLES and let m be the number of items of the collection GROUP_SIZES. Let X_i, ..., X_j (1 ≤ i ≤ j ≤ n) be consecutive variables of the collection of variables VARIABLES such that the following conditions apply:

- All variables X_i, ..., X_j are assigned value 1,
- i = 1 or X_{i-1} ≠ 1,
- j = n or X_{j+1} ≠ 1.

We call such a set of variables a stretch. The span of the stretch is equal to j − i + 1. We now define the condition enforced by the CONSECUTIVE_GROUPS_OF_ONES constraint.

All variables of the VARIABLES collection should be assigned value 0 or 1. In addition there is |GROUP_SIZES| successive stretches of respective span GROUP_SIZES[1].nb, GROUP_SIZES[2].nb, ..., GROUP_SIZES[m].nb.

Example
\[(2, 1), (1, 1, 0, 0, 0, 1, 0)\]

The CONSECUTIVE_GROUPS_OF_ONES constraint holds since the sequence 1 1 0 0 0 1 0 contains a first stretch (i.e., a maximum sequence of 1) of span 2 and a second stretch of span 1.

Typical

|VARIABLES| > 1
range(VARIABLES.var) > 1
**Typical model**

\[ \text{sum}(\text{VARIABLES}.\text{var}) > 2 \]

**Symmetry**

Items of GROUP_SIZES and VARIABLES are simultaneously reversible.

**Usage**

The CONSECUTIVE_GROUPS_OF_ONES constraint can be used in order to model the logigraphe problem.

**See also**

root concept: GROUP.

**Keywords**

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint network structure: Berge-acyclic constraint network.

filtering: arc-consistency.

modelling exercises: logigraphe.

puzzles: logigraphe.
Automaton

Figure 5.221 depicts the automaton associated with the CONSECUTIVE_GROUPS_OF_ONES constraint. To each variable $\text{VAR}_i$ of the collection $\text{VARIABLES}$ corresponds a signature variable that is equal to $\text{VAR}_i$. There is no signature constraint.

CONSECUTIVE_GROUPS_OF_ONES

949
5.90 CONSECUTIVE_VALUES

Origin
Derived from ALLDIFFERENT_CONSECUTIVE_VALUES.

Constraint
CONSECUTIVE_VALUES(VARIABLES)

Argument
VARIABLES : collection(var−dvar)

Restriction
required(VARIABLES, var)

Purpose
Constraint the difference between the largest and the smallest values of the VARIABLES collection to be equal to the number of distinct values assigned to the variables of the VARIABLES collection minus one (i.e., there is no holes at all within the used values).

Example

\[(5, 4, 3, 5)\]

The CONSECUTIVE_VALUES constraint holds since all values between value 3 and value 5 are actually used.

Typical
\[
|VARIABLES| > 1
\]
\[
\text{range}(VARIABLES, var) > 1
\]

Typical model
\[
nval(VARIABLES, var) > 2
\]

Symmetries

- Items of VARIABLES are permutable.
- One and the same constant can be added to the var attribute of all items of VARIABLES.

Counting

## 5.91 CONTAINS_SBOXES

### Description
Geometry, derived from [349]

### Constraint
```plaintext
CONTAINS_SBOXES(K, DIMS, OBJECTS, SBOXES)
```

### Synonym
CONTAINS.

### Types
- **VARIABLES**: `collection(v−dvar)
- **INTEGERS**: `collection(v−int)
- **POSITIVES**: `collection(v−int)

### Arguments
- **K**: `int
- **DIMS**: `sint
- **OBJECTS**: `collection(oid−int, sid−dvar, x − VARIABLES)
- **SBOXES**: `collection(sid−int, t − INTEGERS, l − POSITIVES)

### Restrictions
```plaintext
[VARIABLES] ≥ 1
[INTEGERS] ≥ 1
[POSITIVES] ≥ 1
required(VARIABLES,v)
[VARIABLES] = K
required(INTEGERS,v)
[INTEGERS] = K
required(POSITIVES,v)
[POSITIVES] = K
POSITIVES.v > 0
K > 0
DIMS ≥ 0
DIMS < K
increasing_seq(OBJECTS,[oid])
required(OBJECTS,[oid,sid,x])
OBJECTS.oid ≥ 1
OBJECTS.oid ≤ |OBJECTS|
OBJECTS.sid ≥ 1
OBJECTS.sid ≤ |SBOXES|
[SBOXES] ≥ 1
required(SBOXES,[sid,t,l])
SBOXES.sid ≥ 1
SBOXES.sid ≤ |SBOXES|
do_not_overlap(SBOXES)
```
CONTAINS SBOXES

955

Holds if, for each pair of objects \((O_i, O_j), i < j\), \(O_i\) contains \(O_j\) with respect to a set of dimensions depicted by \(\text{DIMS}\). \(O_i\) and \(O_j\) are objects that take a shape among a set of shapes. Each \(\text{shape}\) is defined as a finite set of shifted boxes, where each shifted box is described by a box in a \(K\)-dimensional space at a given offset (from the origin of the shape) with given sizes.

More precisely, a \(\text{shifted box}\) is an entity defined by its \(\text{shape id} \, \text{sid}\), \(\text{shift offset} \, \text{t}\), and \(\text{sizes} \, \text{l}\). Then, a \(\text{shape}\) is defined as the union of shifted boxes sharing the same \(\text{shape id}\). An \(\text{object}\) is an entity defined by its unique \(\text{object identifier} \, \text{oid}\), \(\text{shape id} \, \text{sid}\), and \(\text{origin} \, \text{x}\).

An object \(O_i\) contains an object \(O_j\) with respect to a set of dimensions depicted by \(\text{DIMS}\) if and only if, for all shifted boxes \(s_j\) associated with \(O_j\), there exists a shifted box \(s_i\) of \(O_i\) such that \(s_i\) contains \(s_j\). A shifted box \(s_i\) contains a shifted box \(s_j\) if and only if, for all dimensions \(d \in \text{DIMS}\), (1) the start of \(s_i\) in dimension \(d\) is strictly less than the start of \(s_j\) in dimension \(d\) and (2) the end of \(s_j\) in dimension \(d\) is strictly less than the end of \(s_i\) in dimension \(d\).

**Example**

\[
\begin{align*}
\text{oid} - 1 & \quad \text{sid} - 1 & \quad x - \langle 1, 1 \rangle, \\
\text{oid} - 2 & \quad \text{sid} - 2 & \quad x - \langle 2, 2 \rangle, \\
\text{oid} - 3 & \quad \text{sid} - 3 & \quad x - \langle 3, 3 \rangle, \\
\text{sid} - 1 & \quad t - \langle 0, 0 \rangle & \quad l - \langle 5, 5 \rangle, \\
\text{sid} - 2 & \quad t - \langle 0, 0 \rangle & \quad l - \langle 3, 3 \rangle, \\
\text{sid} - 3 & \quad t - \langle 0, 0 \rangle & \quad l - \langle 1, 1 \rangle
\end{align*}
\]

Figure 5.223 shows the objects of the example. Since \(O_1\) contains both \(O_2\) and \(O_3\), and since \(O_2\) contains \(O_3\), the \text{CONTAINS_SBOXES} constraint holds.

**Typical**

\(|\text{OBJECTS}| > 1\)

**Symmetries**

- Items of \text{SBOXES} are \text{permutable}.
- Items of \text{OBJECTS.x, SBOXES.t} and \text{SBOXES.l} are \text{permutable (same permutation used)}.

**Arg. properties**

\text{Suffix-contractible wrt. OBJECTS}.

**Remark**

One of the eight relations of the \text{Region Connection Calculus} [349]. The constraint \text{CONTAINS_SBOXES} is a restriction of the original relation since it requires that each shifted box of an object is contained by one shifted box of the other object.

• $\text{all_contains}(\text{DIMENSIONS}, \text{OIDS})$
## 5.92 CORRESPONDENCE

**Origin**
Derived from `SORT_PERMUTATION` by removing the sorting condition.

**Constraint**

correspondence(FROM, PERMUTATION, TO)

**Arguments**

<table>
<thead>
<tr>
<th>Collection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FROM</td>
<td>collection(from=dvar)</td>
</tr>
<tr>
<td>PERMUTATION</td>
<td>collection(var=dvar)</td>
</tr>
<tr>
<td>TO</td>
<td>collection(tvar=dvar)</td>
</tr>
</tbody>
</table>

**Restrictions**

- |PERMUTATION| = |FROM|
- |PERMUTATION| = |TO|
- PERMUTATION.var ≥ 1
- PERMUTATION.var ≤ |PERMUTATION|
- ALLDIFFERENT(PERMUTATION)
- required(FROM,from)
- required(PERMUTATION, var)
- required(TO,tvar)

**Purpose**
The variables of collection FROM correspond to the variables of collection TO according to the permutation PERMUTATION (i.e., FROM[i].from = TO[PERMUTATION[i].var].tvar).

**Example**

\[(1, 9, 1, 5, 2, 1), (6, 1, 3, 5, 4, 2), (9, 1, 1, 2, 5, 1)\]

As illustrated by Figure 5.224, the CORRESPONDENCE constraint holds since:

- The first item FROM[1].from = 1 of collection FROM corresponds to the PERMUTATION[1].var = 6\textsuperscript{th} item of collection TO.
- The second item FROM[2].from = 9 of collection FROM corresponds to the PERMUTATION[2].var = 1\textsuperscript{st} item of collection TO.
- The third item FROM[3].from = 1 of collection FROM corresponds to the PERMUTATION[3].var = 3\textsuperscript{rd} item of collection TO.
- The fourth item FROM[4].from = 5 of collection FROM corresponds to the PERMUTATION[4].var = 5\textsuperscript{th} item of collection TO.
- The fifth item FROM[5].from = 2 of collection FROM corresponds to the PERMUTATION[5].var = 4\textsuperscript{th} item of collection TO.
- The sixth item FROM[6].from = 1 of collection FROM corresponds to the PERMUTATION[6].var = 2\textsuperscript{nd} item of collection TO.

**Typical**

<table>
<thead>
<tr>
<th>Collection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FROM</td>
<td></td>
</tr>
<tr>
<td>range</td>
<td>FROM.from</td>
</tr>
</tbody>
</table>
Figure 5.224: Illustration of the correspondence between the items of the FROM and the TO collections according to the permutation defined by the items of the PERMUTATION collection of the Example slot

Symmetry
All occurrences of two distinct values in FROM.from or TO.tvar can be swapped; all occurrences of a value in FROM.from or TO.tvar can be renamed to any unused value.

Remark
Similar to the SAME constraint except that we also provide the permutation that allows one to go from the items of collection FROM to the items of collection TO.

Algorithm
An arc-consistency filtering algorithm for the CORRESPONDENCE constraint is described in [138, 139]. The algorithm is based on the following ideas:

- First, one can map solutions to the CORRESPONDENCE constraint to perfect matchings in a bipartite graph derived from the domain of the variables of the constraint in the following way: to each variable of the FROM collection there is a from vertex; similarly, to each variable of the TO collection there is a to vertex; finally, there is an edge between the $i^{th}$ from vertex and the $j^{th}$ to vertex if and only if the corresponding domains intersect and if $j$ belongs to the domain of the $i^{th}$ permutation variable.
- Second, Dulmage-Mendelsohn decomposition [157] is used to characterise all edges that do not belong to any perfect matching, and therefore prune the corresponding variables.

See also
implied by: sort_permutation.
specialisation: SAME(PERMUTATION parameter removed).

Keywords
characteristic of a constraint: derived collection.
combinatorial object: permutation.
constraint arguments: constraint between three collections of variables.
filtering: bipartite matching.
final graph structure: acyclic, bipartite, no loop.
Derived Collection

\[
\text{arc} \left( \text{FROM\_PERMUTATION} \right) \rightarrow \text{collection} \left( \text{from\_dvar}, \text{var\_dvar} \right), \\
\text{item} \left( \text{from} \rightarrow \text{FROM\_from\_var} \rightarrow \text{PERMUTATION\_var} \right)
\]

Arc input(s)
FROM\_PERMUTATION TO

Arc generator
\( \text{PRODUCT} \rightarrow \text{collection} \left( \text{from\_permutation}, \text{to} \right) \)

Arc arity
2

Arc constraint(s)
• from\_permutation\_from = to\_tvar
• from\_permutation\_var = to\_key

Graph property(ies)
\( \text{NARC} = |\text{PERMUTATION}| \)

Graph class
• ACYCLIC
• BIPARTITE
• NO_LOOP

Graph model
Parts (A) and (B) of Figure 5.225 respectively show the initial and final graph associated with the Example slot. In both graphs the source vertices correspond to the derived collection FROM\_PERMUTATION, while the sink vertices correspond to the collection TO. Since the final graph contains exactly \(|\text{PERMUTATION}|\) arcs the CORRESPONDENCE constraint holds. As we use the NARC graph property, the arcs of the final graph are stressed in bold.

Signature
Because of the second condition from\_permutation\_var = to\_key of the arc constraint and since both, the var attributes of the collection FROM\_PERMUTATION and the key attributes of the collection TO are all-distinct, the final graph contains at most \(|\text{PERMUTATION}|\) arcs. Therefore we can rewrite the graph property \( \text{NARC} = |\text{PERMUTATION}| \) to \( \text{NARC} \geq |\text{PERMUTATION}| \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).
Figure 5.225: Initial and final graph of the CORRESPONDENCE constraint
5.93 COUNT

<p>| | | | | |</p>
<table>

<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DESCRIPTION</td>
<td>LINKS</td>
<td>GRAPH</td>
<td>AUTOMATON</td>
</tr>
</tbody>
</table>

**Origin**

[108]

**Constraint**

\[
\text{COUNT}(\text{VALUE, VARIABLES, RELOP, LIMIT})
\]

**Synonyms**

\[
\text{OCCURENCEMAX, OCCURENCEMIN, OCCURRENCE.}
\]

**Arguments**

\[
\begin{align*}
\text{VALUE} & : \text{int} \\
\text{VARIABLES} & : \text{collection(var-dvar)} \\
\text{RELOP} & : \text{atom} \\
\text{LIMIT} & : \text{dvar}
\end{align*}
\]

**Restrictions**

\[
\begin{align*}
\text{required(VARIABLES.var)} \\
\text{RELOP} & \in \{=, \neq, <, \geq, >, \leq\}
\end{align*}
\]

**Purpose**

Let \( N \) be the number of variables of the \text{VARIABLES} collection assigned to value \text{VALUE}; Enforce condition \( N \ \text{RELOP} \ \text{LIMIT} \) to hold.

**Example**

\[(5, \langle 4, 5, 5, 4, 5 \rangle, \geq, 2)\]

The COUNT constraint holds since value \text{VALUE} = 5 occurs 3 times within the items of the collection \text{VARIABLES} = \langle 4, 5, 5, 4, 5 \rangle, which is greater than or equal to (RELOP is set to \( \geq \)) \text{LIMIT} = 2.

**Typical**

\[
\begin{align*}
|\text{VARIABLES}| & > 1 \\
\text{range(VARIABLES.var)} & > 1 \\
\text{RELOP} & \in \{=, <, \geq, >, \leq\} \\
\text{LIMIT} & > 0 \\
\text{LIMIT} & < |\text{VARIABLES}|
\end{align*}
\]

**Symmetries**

- Items of \text{VARIABLES} are permutable.
- An occurrence of a value of \text{VARIABLES}.var that is different from \text{VALUE} can be replaced by any other value that is also different from \text{VALUE}.

**Arg. properties**

- **Contractible** wrt. \text{VARIABLES} when \text{RELOP} \in \{<, \leq\}.
- **Extensible** wrt. \text{VARIABLES} when \text{RELOP} \in \{\geq, >\}.
- **Aggregate:** \text{VALUE(id)}, \text{VARIABLES(union)}, \text{RELOP(id)}, \text{LIMIT(+) when RELOP} \in \{<, \leq, \geq, >\}.

**Remark**

Similar to the AMONG constraint. Both, in JaCoP (http://www.jacop.eu/) and in MiniZinc (http://www.minizinc.org/) \text{RELOP} is implicitly set to \( = \).
Reformulation

The \texttt{COUNT(VALUE,VARIABLES,RELOP,LIMIT)} constraint can be expressed in term of the conjunction \texttt{AMONG(N,VARIABLES,\langle VALUE\rangle) \land N \text{ RELOP} LIMIT}.

Systems

\texttt{OCCURRENCE} in \texttt{Choco}, \texttt{COUNT} in \texttt{Gecode}, \texttt{COUNT} in \texttt{JaCoP}, \texttt{COUNT\_EQ} in \texttt{MiniZinc}, \texttt{COUNT\_GEQ} in \texttt{MiniZinc}, \texttt{COUNT\_GT} in \texttt{MiniZinc}, \texttt{COUNT\_LEQ} in \texttt{MiniZinc}, \texttt{COUNT\_LT} in \texttt{MiniZinc}, \texttt{COUNT\_NEQ} in \texttt{MiniZinc}, \texttt{COUNT} in \texttt{SICStus}.

characteristic of a constraint: automaton, automaton with counters.

constraint network structure: alpha-acyclic constraint network(2).

constraint type: value constraint, counting constraint.

filtering: arc-consistency.
Arc input(s) | VARIABLES
---|---
Arc generator | SELF $\rightarrow$ collection(variables)
Arc arity | 1
Arc constraint(s) | variables.var = VALUE
Graph property(ies) | NARC RELOP LIMIT

**Graph model**

Parts (A) and (B) of Figure 5.226 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the loops of the final graph are stressed in bold.

![Graph Model](image)

Figure 5.226: Initial and final graph of the COUNT constraint
Automaton

Figure 5.227 depicts the automaton associated with the COUNT constraint. To each variable $\text{VAR}_i$ of the collection $\text{VARIABLES}$ corresponds a 0-1 signature variable $S_i$. The following signature constraint links $\text{VAR}_i$ and $S_i$: $\text{VAR}_i = \text{VALUE} \Leftrightarrow S_i$.

![Automaton Diagram]

Figure 5.227: Automaton of the COUNT constraint

Figure 5.228: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the COUNT constraint: since all states variables $Q_0, Q_1, \ldots, Q_n$ are fixed to the unique state $s$ of the automaton, the transitions constraints share only the counter variable $C$ and the constraint network is Berge-acyclic.
5.94 COUNTS

Origin
Derived from COUNT.

Constraint
COUNTS(VALUES, VARIABLES, RELOP, LIMIT)

Arguments
VALUES : collection(val–int)
VARIABLES : collection(var–dvar)
RELOP : atom
LIMIT : dvar

Restrictions
required(VALUES, val)
distinct(VALUES, val)
required(VARIABLES, var)
RELOP ∈ [%eq, %neq, %lt, %ge, %gt, %le]

Purpose
Let \( N \) be the number of variables of the VARIABLES collection assigned to a value of the VALUES collection. Enforce condition \( N \) RELOP LIMIT to hold.

Example
\( (\langle 1, 3, 4, 9 \rangle, \langle 4, 5, 5, 4, 1, 5 \rangle, =, 3) \)

Values 1, 3, 4 and 9 of the VALUES collection are assigned to 3 items of the VARIABLES = \( \langle 4, 5, 5, 4, 1, 5 \rangle \) collection. The COUNTS constraint holds since this number is in fact equal (RELOP is set to =) to the last argument of the COUNTS constraint.

Typical
\[
\begin{align*}
|VALUES| & > 1 \\
|VARIABLES| & > 1 \\
\text{range}(VARIABLES.var) & > 1 \\
|VARIABLES| & > |VALUES| \\
RELOP & \in [%lt, %le, %ge, %gt, %le] \\
LIMIT & > 0 \\
LIMIT & < |VARIABLES|
\end{align*}
\]

Symmetries
- Items of VALUES are permutable.
- Items of VARIABLES are permutable.
- An occurrence of a value of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

Arg. properties
- **Contractible** wrt. VARIABLES when RELOP ∈ [%lt, %le].
- **Extensible** wrt. VARIABLES when RELOP ∈ [%gt, %gt].
- **Aggregate**: VALUES(sunion), VARIABLES(union), RELOP(id), LIMIT(+) when RELOP ∈ [%lt, %le, %gt].
COUNTS

Usage
Used in the Constraint(s) on sets slot for defining some constraints like ASSIGN_AND_COUNTS.

Reformulation
The COUNT(VALUES, VARIABLES, RELOP, LIMIT) constraint can be expressed in term of the conjunction AMONG(N, VARIABLES, VALUES) \( \wedge \) N RELOP LIMIT.

Systems
COUNT in Gecode.

Used in
ASSIGN_AND_COUNTS.

See also
assignment dimension added: ASSIGN_AND_COUNTS (assignment dimension introduced).

common keyword: AMONG (value constraint, counting constraint).

specialisation: COUNT (variable \( \in \) VALUES replaced by variable=value).

Keywords
characteristic of a constraint: automaton, automaton with counters.

constraint network structure: alpha-acyclic constraint network(2).

constraint type: value constraint, counting constraint.

filtering: arc-consistency.

final graph structure: acyclic, bipartite, no loop.
Arc input(s) | VARIABLES VALUES
Arc generator | PRODUCT\rightarrow{\text{collection}}(\text{variables}, \text{values})
Arc arity | 2
Arc constraint(s) | variables.var = values.val
Graph property(ies) | NARC \text{ RELOP LIMIT}
Graph class | • ACYCLIC
• BIPARTITE
• NO LOOP

**Graph model**

Because of the arc constraint variables.var = values.val and since each domain variable can take at most one value, **NARC** is the number of variables taking a value in the VALUES collection.

Parts (A) and (B) of Figure 5.229 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

![Graph Model](image)

Figure 5.229: Initial and final graph of the **COUNTS** constraint
Automaton

Figure 5.230 depicts the automaton associated with the COUNTS constraint. To each variable \( \text{VAR}_i \) of the collection VARIABLES corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i \in \text{VALUES} \iff S_i \).

\[
\text{NOT NOTIN} (\text{VAR}_i, \text{VALUES}) \implies \{ C \leftarrow 0 \}
\]

\[
\text{IN} (\text{VAR}_i, \text{VALUES}), \{ C \leftarrow C + 1 \}
\]

\[\text{RELOP LIMIT}\]

Figure 5.230: Automaton of the COUNTS constraint

Figure 5.231: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the COUNTS constraint: since all states variables \( Q_0, Q_1, \ldots, Q_n \) are fixed to the unique state \( s \) of the automaton, the transitions constraints share only the counter variable \( C \) and the constraint network is Berge-acyclic.
5.95 COVEREDBY_SBOXES

**DESCRIPTION**

**Origin**
Geometry, derived from [349]

**Constraint**

```
COVEREDBY_SBOXES(K, DIMS, OBJECTS, SBOXES)
```

**Synonym**

```
COVEREDBY.
```

**Types**

```
VARIABLES : collection(v-dvar)
INTEGERS : collection(v-int)
POSITIVES : collection(v-int)
```

**Arguments**

```
K : int
DIMS : sint
OBJECTS : collection(oid-int, sid-dvar, x - VARIABLES)
SBOXES : collection(sid-int, t - INTEGERS, l - POSITIVES)
```

**Restrictions**

```
| VARIABLES | ≥ 1
| INTEGERS  | ≥ 1
| POSITIVES | ≥ 1

required(VARIABLES, v)
required(INTEGERS, v)
required(POSITIVES, v)
POSITIVES.v > 0
K > 0
DIMS ≥ 0
DIMS < K

increasing_seq(OBJECTS, [oid])
required(OBJECTS, [oid,sid,x])
OBJECTS.oid ≥ 1
OBJECTS.oid ≤ |OBJECTS|
OBJECTS.sid ≥ 1
OBJECTS.sid ≤ |SBOXES|
required(SBOXES, [sid,t,l])
|SBOXES| ≥ 1
SBOXES.sid ≥ 1
SBOXES.sid ≤ |SBOXES|
do_not_overlap(SBOXES)
```
**Purpose**

Holds if, for each pair of objects \((O_i, O_j), \ i < j\), \(O_i\) is covered by \(O_j\) with respect to a set of dimensions depicted by \(DIMS\). \(O_i\) and \(O_j\) are objects that take a shape among a set of shapes. Each *shape* is defined as a finite set of shifted boxes, where each shifted box is described by a box in a \(K\)-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a *shifted box* is an entity defined by its shape id \(sid\), shift offset \(t\), and sizes \(l\). Then, a shape is defined as the union of shifted boxes sharing the same shape id. An *object* is an entity defined by its unique object identifier \(oid\), shape id \(sid\) and origin \(x\).

An object \(O_i\) is covered by an object \(O_j\) with respect to a set of dimensions depicted by \(DIMS\) if and only if, for all shifted box \(s_i\) of \(O_i\), there exists a shifted box \(s_j\) of \(O_j\) such that:

- For all dimensions \(d \in DIMS\), (1) the start of \(s_j\) in dimension \(d\) is less than or equal to the start of \(s_i\) in dimension \(d\), and (2) the end of \(s_j\) in dimension \(d\) is less than or equal to the end of \(s_i\) in dimension \(d\).
- There exists a dimension \(d\) where, (1) the start of \(s_j\) in dimension \(d\) coincide with the start of \(s_i\) in dimension \(d\), or (2) the end of \(s_j\) in dimension \(d\) coincide with the end of \(s_i\) in dimension \(d\).

**Example**

```
2, \{0, 1\},
\begin{aligned}
oid \rightarrow 1 \hspace{1em} & sid \rightarrow 4 \hspace{1em} x \rightarrow \langle 2, 3 \rangle, \\
oid \rightarrow 2 \hspace{1em} & sid \rightarrow 2 \hspace{1em} x \rightarrow \langle 2, 2 \rangle, \\
oid \rightarrow 3 \hspace{1em} & sid \rightarrow 1 \hspace{1em} x \rightarrow \langle 1, 1 \rangle, \\
sid \rightarrow 1 \hspace{1em} & t \rightarrow \langle 0, 0 \rangle \hspace{1em} l \rightarrow \langle 3, 3 \rangle, \\
sid \rightarrow 1 \hspace{1em} & t \rightarrow \langle 3, 0 \rangle \hspace{1em} l \rightarrow \langle 2, 2 \rangle, \\
sid \rightarrow 2 \hspace{1em} & t \rightarrow \langle 0, 0 \rangle \hspace{1em} l \rightarrow \langle 2, 2 \rangle, \\
sid \rightarrow 2 \hspace{1em} & t \rightarrow \langle 2, 0 \rangle \hspace{1em} l \rightarrow \langle 1, 1 \rangle, \\
sid \rightarrow 3 \hspace{1em} & t \rightarrow \langle 0, 0 \rangle \hspace{1em} l \rightarrow \langle 2, 2 \rangle, \\
sid \rightarrow 3 \hspace{1em} & t \rightarrow \langle 2, 1 \rangle \hspace{1em} l \rightarrow \langle 1, 1 \rangle, \\
sid \rightarrow 4 \hspace{1em} & t \rightarrow \langle 0, 0 \rangle \hspace{1em} l \rightarrow \langle 1, 1 \rangle
\end{aligned}
```

Figure 5.232 shows the objects of the example. Since \(O_1\) is covered by both \(O_2\) and \(O_3\), and since \(O_2\) is covered by \(O_3\), the \textsc{coveredby} \textsc{boxes} constraint holds.

**Typical**

\[|\text{OBJECTS}| > 1\]

**Symmetries**

- Items of \textsc{boxes} are permutable.
- Items of \textsc{objects}.\(x\), \textsc{boxes}.\(t\) and \textsc{boxes}.\(l\) are permutable (same permutation used).

**Remark**

One of the eight relations of the Region Connection Calculus [349]. The constraint \textsc{coveredby} \textsc{boxes} is a restriction of the original relation since it requires that each shifted box of an object is covered by one shifted box of the other object.

**See also**

5.96 COVERS_SBOXES

Description

Origin
Geometry, derived from [349]

Constraint

\texttt{COVERS\_SBOXES(K, DIMS, OBJECTS, SBOXES)}

Synonym

\texttt{COVERS}.

Types

\begin{align*}
\text{VARIABLES} & : \text{collection}(v \rightarrow \text{dvar}) \\
\text{INTEGERS} & : \text{collection}(v \rightarrow \text{int}) \\
\text{POSITIVES} & : \text{collection}(v \rightarrow \text{int})
\end{align*}

Arguments

\begin{align*}
K & : \text{int} \\
\text{DIMS} & : \text{ sint} \\
\text{OBJECTS} & : \text{collection}(\text{oid} \rightarrow \text{int}, \text{sid} \rightarrow \text{dvar}, x \rightarrow \text{VARIABLES}) \\
\text{SBOXES} & : \text{collection}(\text{sid} \rightarrow \text{int}, t \rightarrow \text{INTEGERS}, l \rightarrow \text{POSITIVES})
\end{align*}

Restrictions

\begin{align*}
[M & \text{VARIABLES}] \geq 1 \\
[M & \text{INTEGERS}] \geq 1 \\
[M & \text{POSITIVES}] \geq 1 \\
\text{required}(\text{VARIABLES}, v) \\
\text{required}(\text{INTEGERS}, v) \\
\text{required}(\text{POSITIVES}, v) \\
\text{POSITIVES}.v & > 0 \\
K & > 0 \\
\text{DIMS} & \geq 0 \\
\text{DIMS} & < K \\
\text{increasing\_seq}(\text{OBJECTS}, [\text{oid}]) \\
\text{required}(\text{OBJECTS}, [\text{oid}, \text{sid}, x]) \\
\text{OBJECTS}.\text{oid} & \geq 1 \\
\text{OBJECTS}.\text{oid} & \leq |\text{OBJECTS}| \\
\text{OBJECTS}.\text{sid} & \geq 1 \\
\text{OBJECTS}.\text{sid} & \leq |\text{SBOXES}| \\
|\text{SBOXES}| & \geq 1 \\
\text{required}(\text{SBOXES}, [\text{sid}, t, l]) \\
\text{SBOXES}.\text{sid} & \geq 1 \\
\text{SBOXES}.\text{sid} & \leq |\text{SBOXES}| \\
\text{do\_not\_overlap}(\text{SBOXES})
\end{align*}
Purpose

Holds if, for each pair of objects \((O_i, O_j), \ i < j\), \(O_i\) covers \(O_j\) with respect to a set of dimensions depicted by \(\text{DIMS}\). \(O_i\) and \(O_j\) are objects that take a shape among a set of shapes. Each shape is defined as a finite set of shifted boxes, where each shifted box is described by a box in a \(k\)-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a shifted box is an entity defined by its shape id \(\text{sid}\), shift offset \(\text{t}\), and sizes \(l\). Then, a shape is defined as the union of shifted boxes sharing the same shape id. An object is an entity defined by its unique object identifier \(\text{oid}\), shape id \(\text{sid}\) and origin \(x\).

An object \(O_i\) covers an object \(O_j\) with respect to a set of dimensions depicted by \(\text{DIMS}\) if and only if, for all shifted box \(s_j\) of \(O_j\), there exists a shifted box \(s_i\) of \(O_i\) such that:

- For all dimensions \(d \in \text{DIMS}\), (1) the start of \(s_i\) in dimension \(d\) is less than or equal to the start of \(s_j\) in dimension \(d\), and (2) the end of \(s_j\) in dimension \(d\) is less than or equal to the end of \(s_i\) in dimension \(d\).
- There exists a dimension \(d\) where, (1) the start of \(s_i\) in dimension \(d\) coincide with the start of \(s_j\) in dimension \(d\), or (2) the end of \(s_i\) in dimension \(d\) coincide with the end of \(s_j\) in dimension \(d\).

Example

\[
\begin{align*}
2, \{0,1\}, \\
\langle \text{oid} = 1, \text{sid} = 1, x = \langle 1,1 \rangle \rangle, \\
\langle \text{oid} = 2, \text{sid} = 2, x = \langle 2,2 \rangle \rangle, \\
\langle \text{oid} = 3, \text{sid} = 4, x = \langle 2,3 \rangle \rangle, \\
\langle \text{sid} = 1, \text{t} = \langle 0,0 \rangle, \text{l} = \langle 3,3 \rangle \rangle, \\
\langle \text{sid} = 1, \text{t} = \langle 3,0 \rangle, \text{l} = \langle 2,2 \rangle \rangle, \\
\langle \text{sid} = 2, \text{t} = \langle 0,0 \rangle, \text{l} = \langle 2,2 \rangle \rangle, \\
\langle \text{sid} = 2, \text{t} = \langle 2,0 \rangle, \text{l} = \langle 1,1 \rangle \rangle, \\
\langle \text{sid} = 3, \text{t} = \langle 0,0 \rangle, \text{l} = \langle 2,2 \rangle \rangle, \\
\langle \text{sid} = 3, \text{t} = \langle 2,1 \rangle, \text{l} = \langle 1,1 \rangle \rangle, \\
\langle \text{sid} = 4, \text{t} = \langle 0,0 \rangle, \text{l} = \langle 1,1 \rangle \rangle
\end{align*}
\]

Figure 5.233 shows the objects of the example. Since \(O_1\) covers both \(O_2\) and \(O_3\), and since \(O_2\) covers \(O_3\), the \text{COVERS_SBOXES} constraint holds.

Typical

\[|\text{OBJECTS}| > 1\]

Symmetries

- Items of \text{SBOXES} are permutable.
- Items of \text{OBJECTS.x}, \text{SBOXES.t} and \text{SBOXES.l} are permutable (same permutation used).

Arg. properties

Suffix-contractible wrt. \text{OBJECTS}.

Remark

One of the eight relations of the Region Connection Calculus [349]. The constraint \text{COVER_SBOXES} is a relaxation of the original relation since it requires that each shifted box of an object is covered by one shifted box of the other object.

See also

common keyword: \text{CONTAINS_SBOXES, COVEREDBY_SBOXES, DISJOINT_SBOXES, EQUAL_SBOXES, INSIDE_SBOXES, MEET_SBOXES(rcc8), NON_OVERLAP_SBOXES (geometrical constraint,logic), OVERLAP_SBOXES (rcc8)}.

- \text{all_covers}(\text{DIMENSIONS},\text{OIDS})
5.97 CROSSING

**Origin**
Inspired by [131].

**Constraint**
\[ \text{CROSSING}(\text{NCROSS}, \text{SEGMENTS}) \]

**Arguments**
- \( \text{NCROSS} : \text{dvar} \)
- \( \text{SEGMENTS} : \text{collection}(\text{ox} - \text{dvar}, \text{oy} - \text{dvar}, \text{ex} - \text{dvar}, \text{ey} - \text{dvar}) \)

**Restrictions**
- \( \text{NCROSS} \geq 0 \)
- \( \text{NCROSS} \leq (|\text{SEGMENTS}| * |\text{SEGMENTS}| - |\text{SEGMENTS}|) / 2 \)
- \( \text{required}(\text{SEGMENTS}, [\text{ox}, \text{oy}, \text{ex}, \text{ey}]) \)

**Purpose**
\( \text{NCROSS} \) is the number of line segments intersections between the line segments defined by the \( \text{SEGMENTS} \) collection. Each line segment is defined by the coordinates \( (\text{ox}, \text{oy}) \) and \( (\text{ex}, \text{ey}) \) of its two extremities.

**Example**
\[
\begin{pmatrix}
3, & \text{ox} - 1 & \text{oy} - 4 & \text{ex} - 9 & \text{ey} - 2, \\
3, & \text{ox} - 1 & \text{oy} - 1 & \text{ex} - 3 & \text{ey} - 5, \\
3, & \text{ox} - 3 & \text{oy} - 2 & \text{ex} - 7 & \text{ey} - 4, \\
3, & \text{ox} - 9 & \text{oy} - 1 & \text{ex} - 9 & \text{ey} - 4
\end{pmatrix}
\]

Figure 5.234 provides a picture of the example with the corresponding four line segments of the \( \text{SEGMENTS} \) collection. The CROSSING constraint holds since its first argument \( \text{NCROSS} \) is set to 3, which is actually the number of line segments intersections.

**Typical**
\( |\text{SEGMENTS}| > 1 \)
Symmetries

- Items of SEGMENTS are permutable.
- Attributes of SEGMENTS are permutable w.r.t. permutation \((ox, oy) \leftrightarrow (ex, ey)\) (permutation applied to all items).
- One and the same constant can be added to the \(ox\) and \(ex\) attributes of all items of SEGMENTS.
- One and the same constant can be added to the \(oy\) and \(ey\) attributes of all items of SEGMENTS.

Arg. properties

Functional dependency: \(n\)-CROSS determined by SEGMENTS.

See also

common keyword: GRAPH.CROSSING, TWO.LAYER.EDGE.CROSSING (line segments intersection).

Keywords

constraint arguments: pure functional dependency.
final graph structure: acyclic, no loop.
geometry: geometrical constraint, line segments intersection.

(s_2.\text{ox} - s_1.\text{ex}) \cdot (s_1.\text{ey} - s_1.\text{oy}) - (s_1.\text{ex} - s_1.\text{ox}) \cdot (s_2.\text{oy} - s_1.\text{ey})
\end{array} \right) \neq \text{sign} \left( \begin{array}{c}
(s_2.\text{ex} - s_1.\text{ex}) \cdot (s_2.\text{oy} - s_1.\text{oy}) - (s_2.\text{ox} - s_1.\text{ox}) \cdot (s_2.\text{ey} - s_1.\text{ey})
\end{array} \right) 
\right) \)

Graph property(ies)  NARC = NCROSS
Graph class
- ACYCLIC
- NO_LOOP

Graph model  Each line segment is described by the x and y coordinates of its two extremities. In the arc generator we use the restriction \( \prec \) in order to generate a single arc for each pair of segments. This is required, since otherwise we would count more than once a given line segments intersection.

Parts (A) and (B) of Figure 5.235 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold. An arc constraint expresses the fact the two line segments intersect. It is taken from [131, page 889]. Each arc of the final graph corresponds to a line segments intersection.
Figure 5.235: Initial and final graph of the CROSSING constraint
5.98 CUMULATIVE

Origin [1]

Constraint CUMULATIVE(TASKS, LIMIT)

Synonym CUMULATIVE_MAX.

Arguments 

| TASKS | collection
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>(origin-dvar, duration-dvar, end-dvar, height-dvar)</td>
</tr>
<tr>
<td>LIMIT</td>
<td>int</td>
</tr>
</tbody>
</table>

Restrictions

require_at_least(2, TASKS, [origin, duration, end]) 
required(TASKS, height) 
TASKS.duration ≥ 0 
TASKS.origin ≤ TASKS.end 
TASKS.height ≥ 0 
LIMIT ≥ 0

Purpose Cumulative scheduling constraint or scheduling under resource constraints. Consider a set T of tasks described by the TASKS collection. The CUMULATIVE constraint enforces that at each point in time, the cumulated height of the set of tasks that overlap that point, does not exceed a given limit. A task overlaps a point i if and only if (1) its origin is less than or equal to i, and (2) its end is strictly greater than i. It also imposes for each task of T the constraint origin + duration = end.

Example

\[
\begin{pmatrix}
\text{origin} - 1 & \text{duration} - 3 & \text{end} - 4 & \text{height} - 1, \\
\text{origin} - 2 & \text{duration} - 9 & \text{end} - 11 & \text{height} - 2, \\
\text{origin} - 3 & \text{duration} - 10 & \text{end} - 13 & \text{height} - 1, \\
\text{origin} - 6 & \text{duration} - 6 & \text{end} - 12 & \text{height} - 1, \\
\text{origin} - 7 & \text{duration} - 2 & \text{end} - 9 & \text{height} - 3
\end{pmatrix}
\]

Figure 5.236 shows the cumulated profile associated with the example. To each task of the CUMULATIVE constraint, i.e. each line of the example, corresponds a set of rectangles coloured with the same colour: the sum of the lengths of the rectangles corresponds to the duration of the task, while the height of the rectangles (i.e., all the rectangles associated with a task have the same height) corresponds to the resource consumption of the task. The CUMULATIVE constraint holds since at each point in time we do not have a cumulated resource consumption strictly greater than the upper limit 8 enforced by the last argument of the CUMULATIVE constraint.
Figure 5.236: Resource consumption profile corresponding to the five tasks of the Example slot (note that the vertical position of a task does not really matter but is only used for displaying the contribution of a task to the resource consumption profile)

All solutions Figure 5.237 gives all solutions to the following non ground instance of the CUMULATIVE constraint:

\begin{align*}
O_1 &\in [1, 5], D_1 \in [4, 4], E_1 \in [1, 9], H_1 \in [2, 6], \\
O_2 &\in [2, 7], D_2 \in [6, 6], E_2 \in [1, 9], H_2 \in [3, 3], \\
O_3 &\in [3, 6], D_3 \in [3, 6], E_3 \in [1, 9], H_3 \in [1, 2], \\
O_4 &\in [1, 8], D_4 \in [2, 3], E_4 \in [1, 9], H_4 \in [3, 4], \\
\text{CUMULATIVE}(O_1 D_1 E_1 H_1 1, O_2 D_2 E_2 H_2 2, O_3 D_3 E_3 H_3 3, O_4 D_4 E_4 H_4 4, 5).
\end{align*}

Typical

\begin{align*}
|\text{TASKS}| &> 1 \\
\text{range}(\text{TASKS.origin}) &> 1 \\
\text{range}(\text{TASKS.duration}) &> 1 \\
\text{range}(\text{TASKS.end}) &> 1 \\
\text{range}(\text{TASKS.height}) &> 1 \\
\text{TASKS.duration} &> 0 \\
\text{TASKS.height} &> 0 \\
\text{LIMIT} &< \text{sum}(\text{TASKS.height})
\end{align*}
Figure 5.237: All solutions corresponding to the non ground example of the CUMULATIVE constraint of the All solutions slot

**Symmetries**
- Items of TASKS are **permutable**.
- TASKS.duration can be **decreased** to any value $\geq 0$.
- TASKS.height can be **decreased** to any value $\geq 0$.
- One and the same constant can be **added** to the origin and end attributes of all items of TASKS.
- LIMIT can be **increased**.

**Arg. properties**
**Contractible** wrt. TASKS.

**Usage**
The CUMULATIVE constraint occurs in most resource scheduling problems where one has to deal with renewable and/or non-renewable resources:
- **Renewable resources** typically correspond to machines or persons, and tasks require such resources during all their executions (i.e., a resource starts to be used at the beginning of the task and is released at the end of the task). This means that, once a task has finished its work, the resource it was using is available for other tasks. Tasks are defined by their origins, durations, ends and resource consumptions and can not be interrupted. When the duration and resource consumption are not fixed tasks can be defined by their loads, i.e., the product of their durations and resource consumptions. To express the dependency between a non-fixed duration/resource consumption of a task with another decision variable (e.g., to state that the duration of a task depends on its start) one can use the ELEMENT constraint where the decision variable corresponds to the index argument of the ELEMENT constraint.

- **Non-renewable resources** typically correspond to stock or money, i.e., resources that do not come back when a task finishes to use them. In this context the CUMULATIVE constraint is used for modelling producer-consumer problems, i.e., problems where a first set of tasks produces a non-renewable resource, while a second set of tasks consumes this resource so that a limit on the minimum or the maximum stock at each instant is imposed.

The CUMULATIVE constraint is also used as a necessary condition for non-overlapping rectangles (see the DIFFN constraint).

**Remark**

In the original CUMULATIVE constraint of CHIP the LIMIT parameter was a domain variable corresponding to the maximum peak of the resource consumption profile. Given a fixed time frame, this variable could be used as a cost in order to directly minimise the maximum resource consumption peak. Fixing this variable is potentially dangerous since it imposes the maximum peak to be equal to a given target value.

Some systems like Ilog CP Optimizer also assume that a zero-duration task overlaps a point \( i \) if and only if (1) its origin is less than or equal to \( i \), and (2) its end is greater than or equal to \( i \). Under this definition, the height of a zero-duration task is also taken into account in the resource consumption profile.

Note that the concept of cumulative is different from the concept of rectangles non-overlapping even though, most of the time, each task of a ground solution to a CUMULATIVE constraint is simply drawn as a single rectangle. As illustrated by Figure 5.291, this is in fact not always possible (i.e., some rectangles may need to be broken apart). In fact the CUMULATIVE constraint is only a necessary condition for rectangles non-overlapping (see Figure 5.290 and the corresponding explanation in the Algorithm slot of the DIFFN constraint).

In MiniZinc (http://www.minizinc.org/) the tasks of a CUMULATIVE constraint have no end attribute.

**Algorithm**

The first filtering algorithms were related to the notion of compulsory part of a task [261]. They compute a cumulated resource profile of all the compulsory parts of the tasks and prune the origins of the tasks with respect to this profile in order to not exceed the resource capacity. These methods are sometimes called time tabling. Even though these methods are quite local, i.e., a task has a non-empty compulsory part only when the difference between its latest start and its earliest start is strictly less than its duration, it scales well and is therefore widely used. Later on, more global algorithms based on the resource consumption of

---

Even though these more global algorithms usually can prune more early in the search tree, these algorithms do not catch all deductions derived from the cumulated resource profile of compulsory parts.
the tasks on specific intervals were introduced [163, 112, 276]. A popular variant, called edge finding, considers only specific intervals [294]. An efficient implementation of edge finding in $O(kn \log n)$, where $k$ is the number of distinct task heights and $n$ is the number of tasks, based on a specific data structure, so called a cumulative $\Phi$-tree [446], is provided in [445]. When the number of distinct task heights $k$ is not small, a usually almost faster implementation in $O(n^2)$ is described in [241]. A $O(n^{2} \log n)$ filtering algorithm based on tasks that can not be the earliest (or not be the latest) is described in [386].

Within the context of linear programming, the reference [227] provides a relaxation of the CUMULATIVE constraint.

A necessary condition for the CUMULATIVE constraint is obtained by stating a DISJUNCTIVE constraint on a subset of tasks $T$ such that, for each pair of tasks of $T$, the sum of the two corresponding minimum heights is strictly greater than LIMIT. This can be done by applying the following procedure:

- Let $h$ be the smallest minimum height strictly greater than $\lfloor \frac{\text{LIMIT}}{2} \rfloor$ of the tasks of the CUMULATIVE constraint. If no such task exists then the procedure is stopped without stating any DISJUNCTIVE constraint.
- Let $T_h$ denote the set of tasks of the CUMULATIVE constraint for which the minimum height is greater than or equal to $h$. By construction, the tasks of $T_h$ cannot overlap. But we can possibly add one more task as shown by the next step.
- When it exists, we can add one task that does not belong to $T_h$ and such that its minimum height is strictly greater than $\text{LIMIT} - h$. Again, by construction, this task cannot overlap all the tasks of $T_h$.

When the tasks are involved in several CUMULATIVE constraints more sophisticated methods are available for extracting DISJUNCTIVE constraints [18, 17].

In the context where, both the duration and height of all the tasks are fixed, [41] provides two kinds of additional filtering algorithms that are especially useful when the slack $\sigma$ (i.e., the difference between the available space and the sum of the surfaces of the tasks) is very small:

- The first one introduces bounds for the so called cumulative longest hole problem. Given an integer $\epsilon$ that does not exceed the resource limit, and a subset of tasks $T'$ for which the resource consumption is a most $\epsilon$, the cumulative longest hole problem is to find the largest integer $l_{\text{max}}(T')$ such that there is a cumulative placement of maximum height $\epsilon$ involving a subset of tasks of $T'$ where, on one interval $[i, i + l_{\text{max}}(T') - 1]$ of the cumulative profile, the area of the empty space does not exceed $\sigma$.
- The second one used dynamic programming for filtering so called balancing knapsack constraints. When the slack is 0, such constraints express that the total height of tasks ending at instant $i$ must equal the total height of tasks starting at instant $i$. Such constraints can be generalised to non-zero slack.

Bound-consistency algorithms are available for the following relaxations of the CUMULATIVE constraint:

- When the durations and the resource consumptions are all equal to 1, one can use the bound-consistency filtering algorithm of the GLOBAL_CARDINALITY_LOW_UP constraint.
• When the durations are all equal, one can use the bound-consistency filtering algorithm of the `MULTI_INTER_DISTANCE` constraint.

**Systems**

- `CUMULATIVE_MAX` in Choco
- `CUMULATIVE` in Gecode
- `CUMULATIVE` in JaCoP
- `CUMULATIVE` in MiniZinc
- `CUMULATIVE` in SICStus

**See also**

- **assignment dimension added**: `COLOURED_CUMULATIVES` (sum of task heights replaced by number of distinct colours), `CUMULATIVES` (negative heights allowed and assignment dimension added).

**common keyword:**

- `CALENDAR` (scheduling constraint)
- `COLOURED_CUMULATIVE` (resource constraint, sum of task heights replaced by number of distinct values)
- `CUMULATIVE_CONVEX` (resource constraint, task defined by a set of points)
- `CUMULATIVE_PRODUCT` (resource constraint, sum of task heights replaced by product of task heights)
- `CUMULATIVE_WITH_LEVEL_OF_PRIORITY` (resource constraint, a CUMULATIVE constraint for each set of tasks having a priority less than or equal to a given threshold)

**generalisation:** `CUMULATIVE_TWO_D` (task replaced by rectangle with a height).

**implied by:** `DIFFN` (CUMULATIVE is a necessary condition for each dimension of the DIFFN constraint).

**related:**

- `LEX_CHAIN_LESS`, `LEX_CHAIN_LESEQ` (lexicographic ordering on the origins of tasks, rectangles, ...), `ORDERED_GLOBAL_CARDINALITY` (controlling the shape of the cumulative profile for breaking symmetry).

**soft variant:** `SOFT_CUMULATIVE`.

**specialisation:**

- `ATMOST` (task replaced by variable), `BIN_PACKING` (all tasks have a duration of 1 and a fixed height), `DISJUNCTIVE` (all tasks have a height of 1), `GLOBAL_CARDINALITY_LOW_UP` (all tasks have the same duration and height of 1), `MULTI_INTER_DISTANCE` (all tasks have the same duration equal to DIST and the same height of 1).

**used in graph description:** `SUM_CTR`.

**Keywords**

- **characteristic of a constraint**: core, automaton, automaton with array of counters.
- **complexity**: sequencing with release times and deadlines.
- **constraint type**: scheduling constraint, resource constraint, temporal constraint.
- **filtering**: linear programming, dynamic programming, compulsory part, cumulative longest hole problems, Phi-tree, minimum task duration.
- **modelling**: zero-duration task.
- **problems**: producer-consumer.
- **puzzles**: squared squares.

**Cond. implications**

- `CUMULATIVE(TASKS, LIMIT)` with `TASKS.height > 0` implies `COLOURED_CUMULATIVE(TASKS : TASKS, LIMIT : LIMIT)`.

### Constraint(s) on sets

- \( \text{SUM}_{\text{CTR}}(\text{variables}, \leq, \text{LIMIT}) \)

### Graph model

The first graph constraint forces for each task the link between its origin, its duration and its end. The second graph constraint makes sure, for each time point \( t \) corresponding to the start of a task, that the cumulated heights of the tasks that overlap \( t \) does not exceed the limit of the resource.

Parts (A) and (B) of Figure 5.238 respectively show the initial and final graph associated with the second graph constraint of the Example slot. On the one hand, each source vertex of the final graph can be interpreted as a time point. On the other hand the successors of a source vertex correspond to those tasks that overlap that time point. The CUMULATIVE constraint holds since for each successor set \( \mathcal{S} \) of the final graph the sum of the heights of the tasks in \( \mathcal{S} \) does not exceed the limit \( \text{LIMIT} = 8 \).

### Signature

Since \( \text{TASKS} \) is the maximum number of vertices of the final graph of the first graph constraint we can rewrite \( \text{NARC} = |\text{TASKS}| \) to \( \text{NARC} \geq |\text{TASKS}| \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).
Figure 5.238: Initial and final graph of the CUMULATIVE constraint
Automaton

Figure ?? depicts the automaton associated with the CUMULATIVE constraint. To each item of the collection TASKS corresponds a signature variable $S_i$ that is equal to 1.

$$\{C[\_] \leftarrow 0\} \rightarrow s \rightarrow \{\}
\quad \begin{cases} C[\text{ORL}_i] \leftarrow C[\text{ORL}_i] + \text{HEIGHT}_i, \\ C[\text{END}_i] \leftarrow C[\text{END}_i] - \text{HEIGHT}_i \end{cases}
\rightarrow \text{ARITH\_SLIDING}(C; \leq; \text{LIMIT})$$

Quiz

EXERCISE 1 (checking whether a ground instance holds or not)∗

A. Does the constraint CUMULATIVE((1 2 3 3, 2 2 4 2, 4 1 5 1), 4) hold?

B. Does the constraint CUMULATIVE((1 2 3 1, 4 1 5 2), 1) hold?

C. Does the constraint CUMULATIVE((1 2 3 0, 1 2 3 4, 4 1 6 1), 4) hold?

∗Hint: go back to the definition of CUMULATIVE.

EXERCISE 2 (finding all solutions)∗

Give all the solutions to the constraint:

$$\begin{cases} O_1 \in [1, 9], & O_2 \in [1, 9], & O_3 \in [1, 9], & O_4 \in [1, 9], \\ E_1 \in [1, 8], & E_2 \in [1, 8], & E_3 \in [1, 8], & E_4 \in [1, 8], \\ \text{CUMULATIVE}((O_1 \ 1 \ E_1 \ 1, O_2 \ 2 \ E_2 \ 2, O_3 \ 3 \ E_3 \ 5, O_4 \ 4 \ E_4 \ 7), 7). \end{cases}$$

∗Hint: reason first on the two highest tasks and then on the other tasks.
EXERCISE 3 (switching time and resource and breaking symmetry)

Consider a set of 20 tasks for which the duration is given by Table 1, as well as five machines. Each task has to be assigned to one of the five machines in such a way that:

- preemption is not allowed,
- two tasks assigned to a same machine should not overlap.

The goal is to find a schedule that minimises the latest completion time of the tasks.

<td>920</td>
</tr>
</tbody>
</table>

Table 1: Durations of the tasks

A. Model the problem with a single CUMULATIVE constraint and show how to use an extra dummy task to handle the fact that the optimal makespan is initially unknown. Make sure to model the machine to which a task is assigned.

B. Provide a search heuristic that takes into account the durations of the tasks.

C. Show how to modify the previous search heuristic in order to break the symmetry related to the fact that all machines are equivalent.

D. Rather than handling symmetry breaking inside the search heuristic use a symmetry-breaking constraint.

E. Use your favourite solver to find the minimal makespan.

SOLUTION TO EXERCISE 1

A. No, since the first and second tasks overlap at time point 2 and use up to $3 + 2$ resource units which exceeds the resource capacity 4.

B. No, since the second task uses 2 resource units, while the resource capacity is 1.

C. No, since for the third task the origin plus the duration is different from the end ($4 + 1 \neq 6$).
SOLUTION TO EXERCISE 2
(nested disjunctions)

1. Since we have a resource limit of 7 the third task (of height 5) cannot overlap the fourth task (of height 7). Since there is no slack on the time axis (i.e., the difference between the latest end of the third and fourth tasks and their earliest starts is equal to the sum of their durations, \(8 - 1 = 3 + 4\)), this leads to the two configurations shown on the right.

2. Since there is no available space on top of the fourth task, the first and second tasks have to be put on top of the third task. Since on top of the third task we only have a capacity of 2 the first and second tasks cannot overlap. Since there is no remaining slack on the time axis this leads to the two configurations shown on the right.

3. Combining the two previous observations together leads to the four solutions shown below.
SOLUTION TO EXERCISE 3

A. Since there are no temporal constraints, the problem is modelled as a bin-packing problem where each bin represents a machine.

(a) Consider a task to schedule and its counterpart within the CUMULATIVE constraint that models the problem. The origin, the height and the duration of a task in the CUMULATIVE constraint respectively correspond to the machine where the task will be assigned, to its duration and to 1. We set the limit argument of the CUMULATIVE constraint to an upper bound on the makespan, e.g., the sum $\ell$ of the durations of the tasks to schedule.

(b) Finally, to link the makespan to the machines where the tasks are assigned, we create a dummy task of variable height $h$ over all the five bins, i.e., starting at 1 and ending at 6. Note that the need for creating this dummy task explains why we use a CUMULATIVE constraint rather than a BIN_PACKING constraint, for which the maximum capacity is usually fixed.

This leads to the following CUMULATIVE constraint, where w.l.o.g. we omit the end attribute of each task:

$$\forall i \in [1, 20] : m_i \in [1, 5],$$

$$\ell = 44 + 670 + \cdots + 920,$$

$$h \in [0, \ell], \text{makespan} \in [0, \ell], \text{makespan} = \ell - h + 1,$$

CUMULATIVE((m_1 1 44, m_2 1 670, \ldots, m_{20} 1 920, 1 5 h), \ell).

B. To reduce the search space, order the variables $m_1, m_2, \ldots, m_{20}$ by decreasing task durations before fixing them by trying successively all values 1, 2, \ldots, 5. Let $m_{d_1}, m_{d_2}, \ldots, m_{d_{20}}$ denote the corresponding ordered variables.

C. Rather than trying all values 1, 2, \ldots, 5 when fixing a variable $m_{d_i}$, first try all values that are already assigned to the previously fixed variables, and then try only one of the not yet used values, i.e. the smallest one. This amounts to, for example, fixing the first variable $m_{d_1}$ to the first machine, and upon backtracking not trying all other values, between 2 and 5.

D. We use the constraint

$$\text{INT\_VALUE\_PRECEDE\_CHAIN}((1, 2, \ldots, 5), \langle m_{d_1}, m_{d_2}, \ldots, m_{d_{20}} \rangle)$$

to state that the first occurrence of value $i$ within the sequence of variables $m_{d_1}, m_{d_2}, \ldots, m_{d_{20}}$ is located before the first occurrence of value $i + 1$ in the same sequence (with $i \in [1, 4]$).

E. By using the previous model together with the symmetry-breaking constraint we find a minimal value of 2274 shown below. In other words the resource consumption peak is equal to 2273.

```
   |   |   |   |   | 2273
---+---+---+---+---+---------
bin 5 | 5 | 18 | 13 | 7 |
bin 4 | 20 | 2 | 16 | 9 |
bin 3 | 12 | 14 | 10 | 8 |
bin 2 | 4 | 3 | 11 |
bin 1 | 17 | 15 | 6 |
```

An optimal solution where the numbers in the rectangles denote the task identifiers.
### 5.99 CUMULATIVE_CONVEX

**Origin**
Derived from CUMULATIVE

**Constraint**
CUMULATIVE_CONVEX(TASKS, LIMIT)

**Type**
POINTS : collection(var − dvar)

**Arguments**
TASKS : collection(points − POINTS, height − dvar)
LIMIT : int

**Restrictions**
required(POINTS, var)
|POINTS| > 0

required(TASKS, [points, height])
TASKS.height ≥ 0
LIMIT ≥ 0

Cumulative scheduling constraint or scheduling under resource constraints. Consider a set \( \mathcal{T} \) of tasks described by the TASKS collection where each task is defined by:

- A set of distinct points depicting the time interval where the task is actually running: the smallest and largest coordinates of these points respectively give the first and last instant of that time interval.
- A height that depicts the resource consumption used by the task from its first instant to its last instant.

The CUMULATIVE_CONVEX constraint enforces that, at each point in time, the cumulated height of the set of tasks that overlap that point, does not exceed a given limit. A task overlaps a point \( i \) if and only if (1) its origin is less than or equal to \( i \), and (2) its end is strictly greater than \( i \).

**Example**

\[
\left\{ \begin{array}{c} \text{points} = (2, 1, 5) \quad \text{height} = 1, \\
\text{points} = (4, 5, 7) \quad \text{height} = 2, \\
\text{points} = (14, 13, 9, 11, 10) \quad \text{height} = 2 \end{array} \right. , 3 \right. 
\]

Figure 5.240 shows the cumulated profile associated with the example. To each set of points defining a task corresponds a rectangle. The height of each rectangle represents the resource consumption of the associated task. The CUMULATIVE_CONVEX constraint holds since at each point in time we do not have a cumulated resource consumption strictly greater than the upper limit 3 enforced by the last argument of the CUMULATIVE_CONVEX constraint.

**Typical**

|TASKS| > 1

TASKS.height > 0

LIMIT < sum(TASKS.height)
Symmetries

- Items of \text{TASKS} are permutable.
- Items of \text{TASKS}.\text{points} are permutable.
- \text{TASKS}.\text{height} can be decreased to any value $\geq 0$.
- \text{LIMIT} can be increased.

Arg. properties

\text{Contractible} wrt. \text{TASKS}.

Usage

A natural use of the \text{CUMULATIVE}\_\text{CONVEX} constraint corresponds to problems where a task is defined as the convex hull of a set of distinct points $P_1, \ldots, P_n$ that are not initially fixed. Note that, by explicitly introducing a start $S$ and an end $E$ variables, and by using a $\text{MINIMUM}(S, \langle \text{var} - P_1, \ldots, \text{var} - P_n \rangle)$ and a $\text{MAXIMUM}(E, \langle \text{var} - P_1, \ldots, \text{var} - P_n \rangle)$ constraints, one could replace the \text{CUMULATIVE}\_\text{CONVEX} constraint by a \text{CUMULATIVE} constraint. However this hinders propagation.

As a concrete example of use of the \text{CUMULATIVE}\_\text{CONVEX} constraint we present a constraint model for a well-known pattern-sequencing problem \cite{177} (also known to be equivalent to the graph path-width \cite{274} problem) that is based on a single \text{CUMULATIVE}\_\text{CONVEX} constraint. The pattern sequencing problem can be described as follows: Given a 0-1 matrix in which each column $j$ ($1 \leq j \leq p$) corresponds to a product required by the customers and each row $i$ ($1 \leq i \leq c$) corresponds to the order of a particular customer (The entry $c_{ij}$ is equal to 1 if and only if customer $i$ has ordered some quantity of product $j$), the objective is to find a permutation of the products such that the maximum number of open orders at any point in the sequence is minimised. Order $i$ is open at point $k$ in the production sequence if there is a product required in order $i$ that appears at or before position $k$ in the sequence and also a product that appears at or after position $k$ in the sequence.

Before giving the constraint model, let us first provide an instance of the pattern-sequencing problem. Consider the matrix $M_1$ depicted by part (A1) of Fig. 5.241. Part (A2) gives its corresponding cumulated matrix $M_2$ obtained by setting to 1 each 0 of $M_1$ that is both preceded and followed by a 1. Part (A3) depicts the corresponding solution in term of

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig5.240.png}
\caption{Points defining the three tasks of the \textbf{Example} slot and corresponding resource consumption profile (note that the vertical position of a task does not really matter but is only used for displaying the contribution of a task to the resource consumption profile)}
\end{figure}
Figure 5.241: An input matrix for the pattern sequencing problem (A1), its corresponding cumulated matrix (A2), a view in term of tasks (A3) and the corresponding cumulative profile (A4); a second matrix (B1) where column 4 of (A1) is put at the rightmost position.

The idea of the model is to associate to each row (i.e., customer) \( i \) of the cumulated matrix a *stack task* that starts at the first 1 on row \( i \) and ends at the last 1 of row \( i \) (i.e., the task corresponds to the convex hull of the different 1 located on row \( i \)). Then the cost of a solution is simply the maximum height on the corresponding cumulated profile.

For each column \( j \) of the 0-1 matrix initially given there is a variable \( V_j \) ranging from 1
to the number of columns $p$. The value of $V_j$ gives the position of column $j$ in a solution. We put all the stack tasks in a CUMULATIVE_CONVEX constraint, telling that each stack task uses one unit of the resource during all its execution. Since we want to have the same model for different limits on the maximum number of open stacks, and since all variables $V_1, V_2, \ldots, V_p$ have to be distinct, we have an extra dummy task characterised as the convex hull of $V_1, V_2, \ldots, V_p$. This extra dummy task has a height $H$ that has to be maximised. For the matrix depicted by (A1) of Fig. 5.241 we pass to the CUMULATIVE_CONVEX constraint the following collection of tasks:

$$
\begin{align*}
\text{points} &= (P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8) & \text{height} &= 1, \\
\text{points} &= (P_2, P_5) & \text{height} &= 1, \\
\text{points} &= (P_4, P_5, P_6) & \text{height} &= 1, \\
\text{points} &= (P_1, P_2, P_3, P_4, P_5, P_6, P_7, P_8) & \text{height} &= 0
\end{align*}
$$

**Algorithm**

A first natural way to handle the CUMULATIVE_CONVEX constraint is to accumulate the compulsory part [261] of the different tasks in a profile and to prune according to this profile. We give the main ideas for computing the compulsory part of a task and for pruning a task according to the profile of compulsory parts.

**Compulsory part of a task** Given a task $T$ characterised as the convex hull of a set of distinct points $P_1, P_2, \ldots, P_k$, the compulsory part of $T$ corresponds to the, possibly empty, interval $[s_T, e_T]$ where:

- $s_T$ is the largest value $v$ such that, when all variables $P_1, P_2, \ldots, P_k$ are greater than or equal to $v$, all variables $P_1, P_2, \ldots, P_k$ can still take distinct values.
- $e_T$ is the smallest value $v$ such that, when all variables $P_1, P_2, \ldots, P_k$ are less than or equal to $v$, all variables $P_1, P_2, \ldots, P_k$ can still take distinct values.

**Pruning according to the profile of compulsory parts** Given two instants $i$ and $j$ ($i < j$) and a task $T$ characterised as the convex hull of a set of distinct points $P_1, P_2, \ldots, P_k$, assume that $T$ cannot overlap $i$ and $j$ since this would lead exceeding LIMIT, the second argument of the CUMULATIVE_CONVEX constraint. Furthermore assume that, when all variables $P_1, P_2, \ldots, P_k$ are both greater than $i$ and less than $j$, all variables $P_1, P_2, \ldots, P_k$ cannot take distinct values. Then all values of $[i + 1, j - 1]$ can be removed from variables $P_1, P_2, \ldots, P_k$.

The first graph constraint forces for each task that the set of points defining its time interval are all distinct. The second graph constraint makes sure for each time point \( t \), that the cumulated heights of the tasks that overlap \( t \) does not exceed the limit of the resource.

Parts (A) and (B) of Figure 5.242 respectively show the initial and final graph associated with the second graph constraint of the Example slot. On the one hand, each source vertex of the final graph can be interpreted as a time point corresponding to a point used in the definitions of the different tasks. On the other hand, the successors of a source vertex correspond to those tasks that overlap a given time point. The \textsc{cumulative,convex} constraint holds since, for each successor set \( S \) of the final graph, the sum of the heights of the tasks in \( S \) does not exceed the limit \( \text{LIMIT} = 3 \).

</tbody>
</table>

**Purpose**

Consider a set $\mathcal{T}$ of tasks described by the TASKS collection. The CUMULATIVE_PRODUCT constraint forces that at each point in time, the product of the heights of the set of tasks that overlap that point, does not exceed a given limit. A task overlaps a point $i$ if and only if (1) its origin is less than or equal to $i$, and (2) its end is strictly greater than $i$. It also imposes for each task of $\mathcal{T}$ the constraint $\text{origin} + \text{duration} = \text{end}$.

**Example**

$$\begin{pmatrix}
\text{origin} - 1 & \text{duration} - 3 & \text{end} - 4 & \text{height} - 1, \\
\text{origin} - 2 & \text{duration} - 9 & \text{end} - 11 & \text{height} - 2, \\
\text{origin} - 3 & \text{duration} - 10 & \text{end} - 13 & \text{height} - 1, \\
\text{origin} - 6 & \text{duration} - 6 & \text{end} - 12 & \text{height} - 1, \\
\text{origin} - 7 & \text{duration} - 2 & \text{end} - 9 & \text{height} - 3
\end{pmatrix}$$

Figure 5.243 shows the solution associated with the example. To each task of the CUMULATIVE_PRODUCT constraint corresponds a set of rectangles coloured with the same colour: the sum of the lengths of the rectangles corresponds to the duration of the task, while the height of the rectangles (i.e., all the rectangles associated with a task have the same height) corresponds to the height of the task. The profile corresponding to the product of the heights of the tasks that overlap a given point is depicted by a thick red line. The CUMULATIVE_PRODUCT constraint holds since at each point in time the product of the heights of the tasks that overlap that point is not strictly greater than the upper limit 6 enforced by the last argument of the CUMULATIVE_PRODUCT constraint.
Figure 5.243: Resource consumption profile in red corresponding to the product of the heights of the five tasks of the Example slot
Symmetries

- Items of TASKS are permutable.
- TASKS.height can be decreased to any value ≥ 0.
- One and the same constant can be added to the origin and end attributes of all items of TASKS.
- LIMIT can be increased.

Arg. properties

Contractible wrt. TASKS.

Reformulation

The CUMULATIVE_PRODUCT constraint can be expressed in term of a set of reified constraints and of |TASKS| constraints of the form \(h_1 \cdot h_2 \cdots \cdot h_{|\text{TASKS}|} \leq l\):

1. For each pair of tasks TASKS\([i]\), TASKS\([j]\) \((i, j \in [1, |\text{TASKS}|])\) of the TASKS collection we create a variable \(H_{ij}\) which is set to the height of task TASKS\([j]\) if task TASKS\([j]\) overlaps the origin attribute of task TASKS\([i]\), and to 1 otherwise:
   - If \(i = j\):
     - \(H_{ij} = \text{TASKS}[i].\text{height}\).
   - If \(i \neq j\):
     - \(H_{ij} = \text{TASKS}[j].\text{height} \lor H_{ij} = 1\).
     - \((\text{TASKS}[j].\text{origin} \leq \text{TASKS}[i].\text{origin} \land \text{TASKS}[j].\text{end} > \text{TASKS}[i].\text{origin}) \land (H_{ij} = \text{TASKS}[j].\text{height})\) \lor
     - \((\text{TASKS}[j].\text{origin} > \text{TASKS}[i].\text{origin} \lor \text{TASKS}[j].\text{end} \leq \text{TASKS}[i].\text{origin}) \land (H_{ij} = 1))\)

2. For each task TASKS\([i]\) \((i \in [1, |\text{TASKS}|])\) we impose a constraint of the form \(H_{i1} \cdot H_{i2} \cdots \cdot H_{i|\text{TASKS}|} \leq \text{LIMIT}\).

\text{item}(\text{var} - \text{ITEMS}.\text{height})
\end{cases}\)

Constraint(s) on sets \(PRODUCT\_CTR(\text{variables}, \leq, \text{LIMIT})\)

Graph model Parts (A) and (B) of Figure 5.244 respectively show the initial and final graph associated with the second graph constraint of the Example slot. On the one hand, each source vertex of the final graph can be interpreted as a time point. On the other hand the successors of a source vertex correspond to those tasks that overlap that time point. The CUMULATIVE\_PRODUCT constraint holds since for each successor set \(S\) of the final graph the product of the heights of the tasks in \(S\) does not exceed the limit \(\text{LIMIT} = 6\).

Signature Since \(\text{TASKS}\) is the maximum number of vertices of the final graph of the first graph constraint we can rewrite \(\text{NARC} = |\text{TASKS}|\) to \(\text{NARC} \geq |\text{TASKS}|\). This leads to simplify \(\text{NARC}\) to \(\text{NARC}\).
Figure 5.244: Initial and final graph of the CUMULATIVE_PRODUCT constraint
5.101 CUMULATIVE_TWO_D

DESCRIPTION

Origin
Inspired by CUMULATIVE and DIFFN.

Constraint
CUMULATIVE_TWO_D(RECTANGLES, LIMIT)

Arguments
RECTANGLES : collection

(start1−dvar,
size1−dvar,
last1−dvar,
start2−dvar,
size2−dvar,
last2−dvar,
height−dvar)

LIMIT : int

Restrictions
require_at_least(2, RECTANGLES, [start1, size1, last1])
require_at_least(2, RECTANGLES, [start2, size2, last2])
required(RECTANGLES, height)
RECTANGLES.size1 ≥ 0
RECTANGLES.size2 ≥ 0
RECTANGLES.height ≥ 0
LIMIT ≥ 0

Purpose
Consider a set \( \mathcal{R} \) of rectangles described by the RECTANGLES collection. Enforces that at each point of the plane, the cumulated height of the set of rectangles that overlap that point, does not exceed a given limit.

Example

Part (A) of Figure 5.245 shows the 4 parallelepipeds of height 4, 2, 3 and 1 associated with the items of the RECTANGLES collection (parallelepipeds since each rectangle also has a height). Part (B) gives the corresponding cumulated 2-dimensional profile, where each number is the cumulated height of all the rectangles that contain the corresponding region. The CUMULATIVE_TWO_D constraint holds since the highest peak of the cumulated 2-dimensional profile does not exceed the upper limit 4 imposed by the last argument of the CUMULATIVE_TWO_D constraint.
Figure 5.245: Two representations of a 2-dimensional cumulative profile of the Example slot (where the profile provides for each point of coordinates \((c_x, c_y)\) the corresponding sum of the heights of the items intersecting that point): (A) a three dimensional representation and (B) a two dimensional representation from above with the height of the profile in red; as for the CUMULATIVE constraint the position of an item on the \(z\) axis does not matter, i.e. only its height matters.

### Typical

- \(|\text{RECTANGLES}| > 1\)
- \(\text{RECTANGLES}.\text{size1} > 0\)
- \(\text{RECTANGLES}.\text{size2} > 0\)
- \(\text{RECTANGLES}.\text{height} > 0\)
- \(\text{LIMIT} < \text{sum}(\text{RECTANGLES}.\text{height})\)

### Symmetries

- Items of \(\text{RECTANGLES}\) are permutable.
- Attributes of \(\text{RECTANGLES}\) are permutable w.r.t. permutation \((\text{start1}, \text{start2})\) \((\text{size1}, \text{size2})\) \((\text{last1}, \text{last2})\) \((\text{height})\) \(\text{(permutation applied to all items)}\).
- \(\text{RECTANGLES}.\text{height}\) can be decreased to any value \(\geq 0\).
- One and the same constant can be added to the \(\text{start1}\) and \(\text{last1}\) attributes of all items of \(\text{RECTANGLES}\).
- One and the same constant can be added to the \(\text{start2}\) and \(\text{last2}\) attributes of all items of \(\text{RECTANGLES}\).
- \(\text{LIMIT}\) can be increased.

### Arg. properties

Contractible wrt. \(\text{RECTANGLES}\).

### Usage

The \text{CUMULATIVE\_TWO\_D} constraint is a necessary condition for the \text{DIFFN} constraint in 3 dimensions (i.e., the placement of parallelepipeds in such a way that they do not pairwise overlap and that each parallelepiped has his sides parallel to the sides of the placement space).

### Algorithm

A first natural way to handle this constraint would be to accumulate the compulsory part [261] of the different rectangles in a quadtree [378]. To each leave of the quadtree we associate the cumulated height of the rectangles containing the corresponding region.

### Systems

\text{GEOST} in \text{Choco}. 

related: DIFFN (CUMULATIVE\_TWO\_D is a necessary condition for DIFFN: forget one dimension when the number of dimensions is equal to 3).

specialisation: BIN\_PACKING (square of size 1 with a height replaced by task of duration 1), CUMULATIVE (rectangle with a height replaced by task with same height).

Keywords characteristic of a constraint: derived collection.
constraint type: predefined constraint.
filtering: quadtree, compulsory part.
geometry: geometrical constraint.
5.102  CUMULATIVE_WITH_LEVEL_OF_PRIORITY

Origin  H. Simonis

Constraint  CUMULATIVE_WITH_LEVEL_OF_PRIORITY(TASKS, PRIORITIES)

Arguments

\[\text{TASKS} : \text{collection} (\text{priority} - \text{int}, \text{origin} - \text{dvar}, \text{duration} - \text{dvar}, \text{end} - \text{dvar}, \text{height} - \text{dvar})\]

\[\text{PRIORITIES} : \text{collection} (\text{id} - \text{int}, \text{capacity} - \text{int})\]

Restrictions

\[\text{required}(\text{TASKS}, [\text{priority}, \text{height}])\]

\[\text{require.at.least}(2, \text{TASKS}, [\text{origin}, \text{duration}, \text{end}])\]

\[\text{TASKS.priority} \geq 1\]

\[\text{TASKS.priority} \leq |\text{PRIORITIES}|\]

\[\text{TASKS.duration} \geq 0\]

\[\text{TASKS.origin} \leq \text{TASKS.end}\]

\[\text{TASKS.height} \geq 0\]

\[\text{required}(\text{PRIORITIES}, [\text{id}, \text{capacity}])\]

\[\text{PRIORITIES.id} \geq 1\]

\[\text{PRIORITIES.id} \leq |\text{PRIORITIES}|\]

\[\text{increasing.seq}(\text{PRIORITIES}, \text{id})\]

\[\text{increasing.seq}(\text{PRIORITIES}, \text{capacity})\]

Purpose

Consider a set \( \mathcal{T} \) of tasks described by the \text{TASKS} collection where each task has a given priority chosen in the range \([1, \text{PRIORITIES}]\). Let \( \mathcal{T}_i \) denote the subset of tasks of \( \mathcal{T} \) that all have a priority less than or equal to \( i \). For each set \( \mathcal{T}_i \), the CUMULATIVE_WITH_LEVEL_OF_PRIORITY constraint forces that at each point in time, the cumulated height of the set of tasks that overlap that point, does not exceed a given limit. A task overlaps a point \( i \) if and only if (1) its origin is less than or equal to \( i \), and (2) its end is strictly greater than \( i \). Finally, it also imposes for each task of \( \mathcal{T} \) the constraint \( \text{origin} + \text{duration} = \text{end} \).

Example

\[
\begin{pmatrix}
  p - 1 & \text{origin} - 1 & \text{dur} - 2 & \text{end} - 3 & \text{height} - 1,
  p - 1 & \text{origin} - 2 & \text{dur} - 3 & \text{end} - 5 & \text{height} - 1,
  p - 1 & \text{origin} - 5 & \text{dur} - 2 & \text{end} - 7 & \text{height} - 2,
  p - 2 & \text{origin} - 3 & \text{dur} - 2 & \text{end} - 5 & \text{height} - 2,
  p - 2 & \text{origin} - 6 & \text{dur} - 3 & \text{end} - 9 & \text{height} - 1
\end{pmatrix}
\]

\((p \text{ for priority, dur for duration})\)

Figure 5.246 shows the cumulated profile associated with both levels of priority.
To each task of the CUMULATIVE WITH LEVEL OF PRIORITY constraint corresponds a set of rectangles containing the same number (i.e., the position of the task within the TASKS collection): the sum of the lengths of the rectangles corresponds to the duration of the task, while the height of the rectangles (i.e., all the rectangles associated with a task have the same height) corresponds to the resource consumption of the task. Tasks that have a priority of 1 are coloured in pink, while tasks that have a priority of 2 are coloured in blue. The CUMULATIVE WITH LEVEL OF PRIORITY constraint holds since:

- At each point in time the cumulated resource consumption profile of the tasks of priority 1 does not exceed the upper capacity 2 enforced by the first item of the PRIORITIES collection.
- At each point in time the cumulated resource consumption profile of the tasks of priority 1 and 2 does not exceed the upper capacity 3 enforced by the second item of the PRIORITIES collection.

**Typical**

<table>
<thead>
<tr>
<th>TASKS</th>
<th>&gt; 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>range(TASKS.priority)</td>
<td>&gt; 1</td>
</tr>
<tr>

<td>&gt; 0</td>
</tr>
<tr>
<td>PRIORITIES.capacity &lt; sum(TASKS.height)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>TASKS</td>
</tr>
</tbody>
</table>

**Symmetries**

- Items of TASKS are permutable.
- TASKS.priority can be increased to any value \( \leq |PRIORITIES| \).
- TASKS.height can be decreased to any value \( \geq 0 \).
- One and the same constant can be added to the origin and end attributes of all items of TASKS.
- PRIORITIES.capacity can be increased.

**Arg. properties**

Contractible wrt. TASKS.

**Usage**

The CUMULATIVE WITH LEVEL OF PRIORITY constraint was suggested by problems from the telecommunication area where one has to ensure different levels of quality of service. For this purpose the capacity of a transmission link is split so that a given percentage is reserved to each level. In addition we have that, if the capacities allocated to levels 1, 2, . . . , i is not completely used, then level \( i + 1 \) can use the corresponding spare capacity.

**Remark**

The CUMULATIVE WITH LEVEL OF PRIORITY constraint can be modelled by a conjunction of CUMULATIVE constraints. As shown by the next example, the consistency for all variables of the CUMULATIVE constraints does not implies consistency for the corresponding CUMULATIVE WITH LEVEL OF PRIORITY constraint. The following CUMULATIVE WITH LEVEL OF PRIORITY constraint
Figure 5.246: Resource consumption profiles according to both levels of priority for the tasks of the Example slot

\[
\begin{pmatrix}
\text{priority} - \text{1} & \text{origin} - o_1 & \text{duration} - 2 & \text{height} - 2, \\
\text{priority} - \text{1} & \text{origin} - o_2 & \text{duration} - 2 & \text{height} - 1, \\
\text{priority} - \text{2} & \text{origin} - o_3 & \text{duration} - 1 & \text{height} - 3 \\
id - \text{1} & \text{capacity} - 2, \\
id - \text{2} & \text{capacity} - 3
\end{pmatrix}
\]

where the domains of \( o_1, o_2 \) and \( o_3 \) are respectively equal to \( \{1, 2, 3\} \), \( \{1, 2, 3\} \) and \( \{1, 2, 3, 4\} \) corresponds to the following conjunction of CUMULATIVE constraints

\[
\text{cumulative}\left(\begin{pmatrix}
\text{origin} - o_1 & \text{duration} - 2 & \text{height} - 2, \\
\text{origin} - o_2 & \text{duration} - 2 & \text{height} - 1
\end{pmatrix}, 2\right)
\]
Even if the CUMULATIVE constraint could achieve arc-consistency, the previous conjunction of CUMULATIVE constraints would not detect the fact that there is no solution.

See also  
common keyword: CUMULATIVE (resource constraint).
used in graph description: SUM_CTR.

Keywords  
characteristic of a constraint: derived collection.
constraint type: scheduling constraint, resource constraint, temporal constraint.
modelling: zero-duration task.
Within the context of the second graph constraint, part (A) of Figure 5.247 shows the initial graphs associated with priorities 1 and 2 of the Example slot. Part (B) of Figure 5.247 shows the corresponding final graphs associated with priorities 1 and 2. On the one hand, each source vertex of the final graph can be interpreted as a time point \( p \). On the other hand the successors of a source vertex correspond to those tasks that both overlap that time point \( p \) and have a priority less than or equal to a given level. The CUMULATIVE_WITH_LEVEL_OF_PRIORITY constraint holds since for each successor set \( S \) of the final graph the sum of the height of the tasks in \( S \) is less than or equal to the
capacity associated with a given level of priority.

Figure 5.247: Initial and final graph of the CUMULATIVE_WITH_LEVEL_OF_PRIORITY constraint

**Signature**

Since TASKS is the maximum number of vertices of the final graph of the first graph constraint we can rewrite NARC = |TASKS| to NARC ≥ |TASKS|. This leads to simplify NARC to NARC.
5.103 CUMULATIVES

**Origin** [35]

**Constraint**

CUMULATIVES(TASKS, MACHINES, CTR)

**Arguments**

- TASKS : collection
  - machine - dvar,
  - origin - dvar,
  - duration - dvar,
  - end - dvar,
  - height - dvar
- MACHINES : collection(id - int, capacity - int)
- CTR : atom

**Restrictions**

- required(TASKS, [machine, height])
- require_at_least(2, TASKS, [origin, duration, end])
- in_attr(TASKS, machine, MACHINES, id)
- TASKS.duration ≥ 0
- TASKS.origin ≤ TASKS.end
- |MACHINES| > 0
- required(MACHINES, [id, capacity])
- distinct(MACHINES, id)
- CTR ∈ [≤, ≥]

**Purpose**

Consider a set $T$ of tasks described by the TASKS collection. When CTR is equal to ≤ (respectively ≥), the CUMULATIVES constraint forces the following condition for each machine $m$: At each point in time, where at least one task assigned on machine $m$ is present, the cumulated height of the set of tasks that both overlap that point and are assigned to machine $m$ should be less than or equal to (respectively greater than or equal to) the capacity associated with machine $m$. A task overlaps a point $i$ if and only if (1) its origin is less than or equal to $i$, and (2) its end is strictly greater than $i$. It also imposes for each task of $T$ the constraint $\text{origin} + \text{duration} = \text{end}$.

**Example**

( $m$ for machine, $dur$ for duration )

\[
\begin{array}{cccc}
  m - 1 & \text{origin} - 2 & \text{dur} - 2 & \text{end} - 4 & \text{height} - 2, \\
  m - 1 & \text{origin} - 1 & \text{dur} - 4 & \text{end} - 5 & \text{height} - 1, \\
  m - 1 & \text{origin} - 4 & \text{dur} - 2 & \text{end} - 6 & \text{height} - 1, \\
  m - 1 & \text{origin} - 2 & \text{dur} - 3 & \text{end} - 5 & \text{height} - 2, \\
  m - 1 & \text{origin} - 5 & \text{dur} - 2 & \text{end} - 7 & \text{height} - 2, \\
  m - 2 & \text{origin} - 3 & \text{dur} - 2 & \text{end} - 5 & \text{height} - 1, \\
  m - 2 & \text{origin} - 1 & \text{dur} - 4 & \text{end} - 5 & \text{height} - 1, \\
\end{array}
\]

\[
\langle \text{id} - 1 \text{ capacity} - 0, \text{id} - 2 \text{ capacity} - 0, \rangle, \geq
\]

( $m$ for machine, $dur$ for duration )
Figure 5.248 shows with a thick line the cumulated profile on the two machines described by the MACHINES collection. Within this profile a task with a positive (respectively negative) height is represented by a pink (respectively blue) rectangle, where the length of the rectangle corresponds to the duration of the task. The CUMULATIVES constraint holds since, both on machines 1 and 2, we have that at each point in time the cumulated resource consumption is greater than or equal to the limit 0 enforced by the last argument (i.e., the attribute capacity of the items of the MACHINES collection) of the CUMULATIVES constraint (i.e., we have a limit of 0 both on machines 1 and 2).

Figure 5.248: Resource consumption profiles on the different machines for the tasks of the Example slot

(A) tasks on machine 1

(B) tasks on machine 2
Typical

|TASKS| > 1
range(TASKS.machine) > 1
range(TASKS.origin) > 1
range(TASKS.duration) > 1
range(TASKS.end) > 1
range(TASKS.height) > 1
TASKS.duration > 0
TASKS.height ≠ 0
|MACHINES| > 1
MACHINES.capacity < \(|\text{sum}(\text{TASKS.height})|
|TASKS| > |MACHINES|

Symmetries

- Items of TASKS are **permutable**.
- Items of MACHINES are **permutable**.
- All occurrences of two distinct values in TASKS.machine or MACHINES.id can be **swapped**; all occurrences of a value in TASKS.machine or MACHINES.id can be **renamed** to any unused value.

Arg. properties

Contractible wrt. TASKS when REL\(\text{OP} \in [\leq]\) and minval(TASKS.height) ≥ 0.

Usage

As shown in the **Example** slot, the CUMULATIVES constraint is useful for covering problems where different demand profiles have to be covered by a set of tasks. This is modelled in the following way:

- To each demand profile is associated a given machine \(m\) and a set of tasks for which all attributes (machine, origin, duration, end, height) are fixed; moreover the machine attribute is fixed to \(m\) and the height attribute is strictly negative. For each machine \(m\) the cumulated profile of all the previous tasks constitutes the demand profile to cover.

- To each task that can be used to cover the demand is associated a task for which the height attribute is a positive integer; the height attribute describes the amount of demand that can be covered by the task at each instant during its execution (between its origin and its end) on the demand profile associated with the machine attribute.

- In order to express the fact that each demand profile should completely be covered, we set the capacity attribute of each machine to 0. We can also relax the constraint by setting the capacity attribute to a negative number that specifies the maximum allowed uncovered demand at each instant.

The demand profiles might also not be completely fixed in advance.

When all the heights of the tasks are non-negative, one other possible use of the CUMULATIVES constraint is to enforce to reach a minimum level of resource consumption. This is imposed on those time points that are overlapped by at least one task.

By introducing a dummy task of height 0, of origin the minimum origin of all the tasks and of end the maximum end of all the tasks, this can also be imposed between the first and the last utilisation of the resource.

Finally the CUMULATIVES constraint is also useful for scheduling problems where several **cumulative** machines are available and where you have to assign each task on a specific machine.
Three filtering algorithms for this constraint are described in [35].

Systems

CUMULATIVES in Gecode, CUMULATIVES in SICStus.

Constraint(s) on sets  
SUM CTR(variables, CTR, MACHINES.capacity)

Graph model  
Within the context of the second graph constraint, part (A) of Figure 5.249 shows the initial graphs associated with machines 1 and 2 of the Example slot. Part (B) of Figure 5.249 shows the corresponding final graphs associated with machines 1 and 2. On the one hand, each source vertex of the final graph can be interpreted as a time point \( p \) on a specific machine \( m \). On the other hand the successors of a source vertex correspond to those tasks that both overlap that time point \( p \) and are assigned to machine \( m \). Since they do not have any successors we have eliminated those vertices corresponding to the end of the last three tasks of the TASKS collection. The CUMULATIVES constraint holds since for each successor
set $S$ of the final graph the sum of the height of the tasks in $S$ is greater than or equal to the capacity of the machine corresponding to the time point associated with $S$.

Figure 5.249: Initial and final graph of the CUMULATIVES constraint

**Signature**

Since $NARC$ is the maximum number of vertices of the final graph of the first graph constraint we can rewrite $NARC = |TASKS|$ to $NARC \geq |TASKS|$. This leads to simplify $NARC$ to $NARC$. 
5.104  CUTSET

Origin  [165]

Constraint  CUTSET(SIZE_CUTSET, NODES)

Arguments
- SIZE_CUTSET : dvar
- NODES : collection(index−int, succ−sint, bool−dvar)

Restrictions
- SIZE_CUTSET ≥ 0
- SIZE_CUTSET ≤ |NODES|
- required(NODES,[index,succ, bool])
- NODES.index ≥ 1
- NODES.index ≤ |NODES|
- distinct(NODES,index)
- NODES.bool ≥ 0
- NODES.bool ≤ 1

Purpose  Consider a digraph $G$ with $n$ vertices described by the NODES collection. Enforces that the subset of kept vertices of cardinality $n - SIZE_CUTSET$ and their corresponding arcs form a graph without circuit.

Example

The CUTSET constraint holds since the vertices of the NODES collection for which the bool attribute is set to 1 correspond to a graph without circuit and since exactly one (SIZE_CUTSET = 1) vertex has its bool attribute set to 0.

Typical
- SIZE_CUTSET > 0
- SIZE_CUTSET ≤ |NODES|
- |NODES| > 1

Symmetry  Items of NODES are permutable.

Usage  The article [165] introducing the CUTSET constraint mentions applications from various areas such that deadlock breaking or program verification.

Remark  The undirected version of the CUTSET constraint corresponds to the minimum feedback vertex set problem.

Algorithm  The filtering algorithm presented in [165] uses graph reduction techniques inspired from Levy and Low [271] as well as from Lloyd, Soffa and Wang [275].
Keywords

application area: deadlock breaking, program verification.
constraint type: graph constraint.
final graph structure: circuit, directed acyclic graph, acyclic, no loop.
problems: minimum feedback vertex set.
Arc input(s) NODES
Arc generator
CLIQUE→collection(nodes1,nodes2)
Arc arity 2
Arc constraint(s)
• IN_SET(nodes2.index,nodes1.succ)
• nodes1.bool = 1
• nodes2.bool = 1
Graph property(ies)
• MAX_NSCC ≤ 1
• NVERTEX = |NODES| − SIZE_CUTSET
Graph class
• ACYCLIC
• NO_LOOP

Graph model
We use a set of integers for representing the successors of each vertex. Because of the arc constraint, all arcs such that the bool attribute of one extremity is equal to 0 are eliminated; therefore all vertices for which the bool attribute is equal to 0 are also eliminated (since they will correspond to isolated vertices). The graph property MAX_NSCC ≤ 1 enforces the size of the largest strongly connected component to not exceed 1; therefore, the final graph cannot contain any circuit.

Part (A) of Figure 5.250 shows the initial graph from which we have chosen to start. It is derived from the set associated with each vertex. Each set describes the potential values of the succ attribute of a given vertex. Part (B) of Figure 5.250 gives the final graph associated with the Example slot. Since we use the NVERTEX graph property, the vertices of the final graph are stressed in bold. The CUTSET constraint holds since the final graph does not contain any circuit and since the number of removed vertices SIZE_CUTSET is equal to 1.

Figure 5.250: Initial and final graph of the CUTSET set constraint
5.105 CYCLE

Origin [47]

Constraint CYCLE(NCYCLE, NODES)

Arguments NCYCLE : dvar
NODES : collection(index=int, succ=dvar)

Restrictions NCYCLE ≥ 1
NCYCLE ≤ |NODES|
required(NODES,[index, succ])
NODES.index ≥ 1
NODES.index ≤ |NODES|
distinct(NODES,index)
NODES.succ ≥ 1
NODES.succ ≤ |NODES|

Purpose Consider a digraph G described by the NODES collection. NCYCLE is equal to the number of circuits for covering G in such a way that each vertex of G belongs to a single circuit. NCYCLE can also be interpreted as the number of cycles of the permutation associated with the successor variables of the NODES collection.

Example

Consider a digraph G described by the NODES collection. NCYCLE is equal to the number of circuits for covering G in such a way that each vertex of G belongs to a single circuit. NCYCLE can also be interpreted as the number of cycles of the permutation associated with the successor variables of the NODES collection.

```
Example

(2, { index - 1 succ - 2,  
   index - 2 succ - 1,  
   index - 3 succ - 5,  
   index - 4 succ - 3,  
   index - 5 succ - 4 }  
1, { index - 3 succ - 1,  
   index - 4 succ - 3,  
   index - 5 succ - 4 }  
5, { index - 3 succ - 3,  
   index - 4 succ - 4,  
   index - 5 succ - 5 }  
```
In the first example we have the following 2 (NCYCLE = 2) cycles: 1 → 2 \rightarrow 1 and 3 → 5 \rightarrow 4 \rightarrow 3. Consequently, the corresponding CYCLE constraint holds.

In the second example we have 1 (NCYCLE = 1) cycle: 1 → 2 \rightarrow 4 \rightarrow 3 \rightarrow 1.

In the third example we have the following 5 (NCYCLE = 5) cycles: 1 → 1, 2 → 2, 3 → 3, 4 → 4 and 5 → 5.

Figure 5.251 gives all solutions to the following non ground instance of the CYCLE constraint: \( N \in [1, 2], V_1 \in [2, 4], V_2 \in [2, 3], V_3 \in [1, 6], V_4 \in [2, 5], V_5 \in [2, 3], V_6 \in [1, 6], \) CYCLE(\( N, \{1 \_1, \ 2 \_2, \ 3 \_3, \ 4 \_4, \ 5 \_5, \ 6 \_6\}\)).

**All solutions**

1. (1, \langle 1 4 2 3 3 6 4 5 5 2 6 1\rangle)
2. (2, \langle 1 4 2 3 3 6 4 5 5 3 6 1\rangle)
3. (2, \langle 1 4 2 3 3 1 4 5 5 2 6 6\rangle)

Figure 5.251: All solutions corresponding to the non ground example of the CYCLE constraint of the **All solutions** slot

**Typical**

\( NCYCLE < \left| NODES \right| \)
\( \left| NODES \right| > 2 \)

**Symmetries**

- Items of NODES are *permutable*.
- Attributes of NODES are *permutable* w.r.t. permutation (\( index, succ \)) (permutable applied to all items).
**Arg. properties**

Functional dependency: 

\( \text{NCYCLE determined by NODES.} \)

**Usage**

The PhD thesis of Éric Bourreau [93] mentions the following applications of extensions of the CYCLE constraint:

- The balanced Euler knight problem where one tries to cover a rectangular chessboard of size \( N \cdot M \) by \( C \) knights that all have to visit between \( 2 \cdot \lfloor \lfloor (N \cdot M)/C \rfloor /2 \) and \( 2 \cdot \lceil \lceil (N \cdot M)/C \rceil /2 \) distinct locations. For some values of \( N, M \) and \( C \) there does not exist any solution to the previous problem. This is the case, for example, when \( N = M = C = 6 \). Figure 5.252 depicts the graph associated with the \( 6 \times 6 \) chessboard as well as examples of balanced solutions with respectively 1, 2, 3, 4 and 5 knights.

- Some pick-up delivery problems where a fleet of vehicles has to transport a set of orders. Each order is characterised by its initial location, its final destination and its weight. In addition one also has to take into account the capacity of the different vehicles.

**Remark**

In the original CYCLE constraint of CHIP the index attribute was not explicitly present. It was implicitly defined as the position of a variable in a list.

In an early version of the CHIP there was a constraint named CIRCUIT that, from a declarative point of view, was equivalent to cycle(1, NODES). In ALICE [267] the CIRCUIT constraint was also present.

Given a complete digraph of \( n \) vertices as well as an unrestricted number of circuits \( \text{NCYCLE} \), the total number of solutions to the corresponding CYCLE constraint corresponds to the sequence A000142 of the On-Line Encyclopedia of Integer Sequences [403]. Given a complete digraph of \( n \) vertices as well as a fixed number of circuits \( \text{NCYCLE} \) between 1 and \( n \), the total number of solutions to the corresponding CYCLE constraint corresponds to the so called Stirling number of first kind.

**Algorithm**

Since all succ variables have to take distinct values one can reuse the algorithms associated with the ALLDIFFERENT constraint. A second necessary condition is to have no more than \( \text{NCYCLE} \) strongly connected components. Pruning for enforcing this condition, as soon as we have \( \text{NCYCLE} \) strongly connected components, can be done by forcing all strong bridges to belong to the final solution, since otherwise we would have more than \( \text{NCYCLE} \) strongly connected components. Since all the vertices of a circuit belong to the same strongly connected component an arc going from one strongly connected component to another strongly connected component has to be removed.
Reformulation

Let $n$ and $s_1, s_2, \ldots, s_n$ respectively denote the number of vertices (i.e., NODES) and the successor variables associated with vertices $1, 2, \ldots, n$. The CYCLE constraint can be reformulated as a conjunction of one ALLDIFFERENT constraint, $n \cdot (n - 1)$ ELEMENT constraints, $n$ MINIMUM constraints, and one NVALUE constraint.

- First, we state an ALLDIFFERENT constraint for enforcing distinct values to be assigned to the successor variables.
- Second, the key idea is to extract for each vertex $i$ (with $i \in [1, n]$) all the vertices that belong to the same cycle. This is done by stating a conjunction of $n - 1$ ELEMENT constraints of the form:
  \[
  \text{ELEMENT}(i, \{s_1, s_2, \ldots, s_n\}, s_i, 1), \\
  \text{ELEMENT}(s_i, 1, \{s_1, s_2, \ldots, s_n\}, s_i, 2), \\
  \text{ELEMENT}(s_i, n-2, \{s_1, s_2, \ldots, s_n\}, s_i, n-1).
  \]
  Then, using a MINIMUM constraint, we get a unique representative for the cycle containing vertex $i$.
- Third, using a NVALUE constraint, we get the number of distinct cycles.

Cond. implications

- \( \text{CYCLE}(\text{NCYCLE}, \text{NODES}) \)
  with \( \text{NCYCLE} = 1 \)
  implies \( \text{BALANCE}_\text{CYCLE}(\text{BALANCE}, \text{NODES}) \)
  when \( \text{BALANCE} = 0 \).

- \( \text{CYCLE}(\text{NCYCLE}, \text{NODES}) \)
  implies \( \text{PERMUTATION}(\text{VARIABLES} : \text{NODES}) \).
Figure 5.252: Graph of potential moves of a $6 \times 6$ chessboard, corresponding balanced knight’s tours with 1 up to 5 knights, and collection of nodes passed to the CYCLE constraint corresponding to the solution with 5 knights; note that there is no balanced knight’s tour on a $6 \times 6$ chessboard where each knight exactly performs 6 moves.
From the restrictions and from the arc constraint, we deduce that we have a bijection from the successor variables to the values of interval $[1, |\text{NODES}|]$. With no explicit restrictions it would have been impossible to derive this property.

In order to express the binary constraint that links two vertices one has to make explicit the identifier of the vertices. This is why the CYCLE constraint considers objects that have two attributes:

- One fixed attribute `index` that is the identifier of the vertex,
- One variable attribute `succ` that is the successor of the vertex.

The graph property $\text{NTREE} = 0$ is used in order to avoid having vertices that both do not belong to a circuit and have at least one successor located on a circuit. This concretely means that all vertices of the final graph should belong to a circuit.

Parts (A) and (B) of Figure 5.253 respectively show the initial and final graph associated with the first example of the Example slot. Since we use the NCC graph property, we show the two connected components of the final graph. The constraint holds since all the vertices belong to a circuit (i.e., $\text{NTREE} = 0$) and since $\text{NCYCLE} = \text{NCC} = 2$.

Figure 5.253: Initial and final graph of the CYCLE constraint
EXERCISE 1 (checking whether a ground instance holds or not)\(^a\)

A. Does the constraint \(\text{CYCLE}(1, (1 \ 2 \ 1 \ 3 \ 2))\) hold?

B. Does the constraint \(\text{CYCLE}(2, (1 \ 3 \ 2 \ 3 \ 1))\) hold?

C. Does the constraint \(\text{CYCLE}(3, (1 \ 1 \ 2 \ 2 \ 3))\) hold?

D. Does the constraint \(\text{CYCLE}(2, (1 \ 5 \ 2 \ 4 \ 3 \ 4 \ 2 \ 5 \ 1))\) hold?

\(^a\)Hint: go back to the definition of \(\text{CYCLE}\).

EXERCISE 2 (finding all solutions)\(^b\)

Give all the solutions to the constraint:

\[
\begin{align*}
N &\in \{2, 4\}, \\
V_1 &\in \{1, 3, 4, 5\}, & V_2 &\in \{3, 4\}, & V_3 &\in \{2, 3, 5, 6\}, \\
V_4 &\in \{1, 4, 6\}, & V_5 &\in \{2, 6\}, & V_6 &\in \{3, 4, 6\}, \\
\text{CYCLE}(N, (1 \ V_1, 2 \ V_2, 3 \ V_3, 4 \ V_4, 5 \ V_5, 6 \ V_6)).
\end{align*}
\]

\(^b\)Hint: follow the order induced by the functional dependency between the arguments of \(\text{CYCLE}\), start with variables that have the smallest domain.

EXERCISE 3 (identifying infeasible values)\(^c\)

A. Describe the following digraph \(\mathcal{G}\) in terms of successor variables and their corresponding domains. Give the implicit assumption behind this description.

B. Model with a single \(\text{CYCLE}\) constraint the problem of finding a Hamiltonian cycle in the graph \(\mathcal{G}\).

C. Identify variable-value pairs that do not belong to any solution to the \(\text{CYCLE}\) constraint stated in the previous question.

\(^c\)Hint: make a link between the successor variables and the arcs of the graph, identify the basic constraint on the successor variables, make a what-if reasoning with respect to the arcs and the strongly connected components.

\(^c\)Given a digraph \(\mathcal{G}\) with \(p\) vertices, a **Hamiltonian cycle** of \(\mathcal{G}\) is a succession of arcs \(v_1 \mapsto v_2, v_2 \mapsto v_3, \ldots, v_{p-1} \mapsto v_p, v_p \mapsto v_1\) of \(\mathcal{G}\) such that the vertices \(v_1, v_2, \ldots, v_p\) are all distinct.
EXERCISE 4 (variable-based degree of violation)

A. Compute the variable-based degree of violation\(^4\) of the following constraints:

(a) \(\text{CYCLE}(4, \langle 1, 2, 3, 4, 1, 4 \rangle)\).
(b) \(\text{CYCLE}(1, \langle 1, 3, 2, 4, 3, 4 \rangle)\).
(c) \(\text{CYCLE}(6, \langle 1, 2, 2, 3, 4, 4, 5, 6, 6 \rangle)\).

B. Give a formula for evaluating the variable-based degree of violation of any ground instance of the \(\text{CYCLE}\) constraint.

\(^4\)Hint: focus first on the basic constraint on the successor variables, then on the first argument of \(\text{CYCLE}\).

Given a constraint for which all variables are fixed, the variable-based degree of violation is the minimum number of variables to assign differently in order to satisfy the constraint.

EXERCISE 5 (De Bruijn sequence)

Give an alphabet \(A = \{0, 1, \ldots, n - 1\}\) and an integer \(m > 0\) the corresponding De Bruijn digraph \(G_n^m = (V, E)\) of order \(m\) is defined as follows:

- The set of vertices \(V\) consist of every potential word of length \(m\) over the alphabet \(A\).
- The set \(E\) contains all arcs \(w_1 \rightarrow w_2\) where \(w_1\) and \(w_2\) are words of length \(m\) over the alphabet \(A\) such that the last \(m - 1\) letters of \(w_1\) coincide with the first \(m - 1\) first letters of \(w_2\).

Given an alphabet \(A = \{0, 1, \ldots, n - 1\}\) and an integer \(m > 0\) a De Bruijn sequence \(s_n^m\) of order \(m\) is a word over the alphabet \(A\) such that every word of length \(m\) over the alphabet \(A\) occurs\(^5\) exactly once in \(s\).

A. Given an alphabet \(A = \{0, 1, \ldots, n - 1\}\) define a De Bruijn sequence of order \(m\) wrt the De Bruijn digraph \(G_n^m\) of order \(m\) defined on the same alphabet \(A\). Illustrate this link on the De Bruijn sequence \(0 1 0 1 1 0 0\) when \(n = 2, m = 3\) and \(A = \{0, 1\}\).

B. Based on the previous correspondence give a compact model for De Bruijn sequences of order \(m\) that uses a single \(\text{CYCLE}\) constraint.

\(^5\)Hint: define the vertices of the De Bruijn digraph \(G_n^m\), define the arcs of \(G_n^m\), search a pattern on \(G_n^m\) corresponding to a De Bruijn sequence.

\(^6\)A word \(w = w_0 w_1 \ldots w_{m-1}\) occurs in a sequence \(s = s_0 s_1 \ldots s_{p-1}\) \((p \geq m)\) if there exists a position \(i\) \((0 \leq i < p)\) such that \(w_0 = s_i, w_1 = s_{(i+1) \mod p}, \ldots, w_{m-1} = s_{(i+m-1) \mod p}\).
SOLUTION TO EXERCISE 1

A. No, since the successor attributes 2, 1, 2 are not all different.
B. Yes, since we have two cycles namely 1 \rightarrow 3 \rightarrow 1 and 2 \rightarrow 2.
C. Yes, since we have three cycles namely 1 \rightarrow 1, 2 \rightarrow 2 and 3 \rightarrow 3.
D. No, since we have three cycles namely 1 \rightarrow 5 \rightarrow 1, 2 \rightarrow 4 \rightarrow 2 and 3 \rightarrow 3, rather than two cycles as stated by the first argument of the CYCLE constraint.

SOLUTION TO EXERCISE 2

(variables of a same cycle are coloured with the same colour)

</tbody>
</table>
SOLUTION TO EXERCISE 3

A. To each vertex $v$ of $G$ we associate a successor variable $S_v$ whose initial domain is set to the labels of the successors of $v$. Thus we have:

$$\begin{align*}
S_1 &\in \{2, 6\}, & S_2 &\in \{1, 2, 3, 4\}, & S_3 &\in \{1, 3\}, \\
S_4 &\in \{2, 3\}, & S_5 &\in \{2, 5, 6\}, & S_6 &\in \{2, 5\}.
\end{align*}$$

The implicit hypothesis is that, in solutions to the modelled problem, each vertex of the corresponding induced subgraph of $G$ has exactly one successor.

B. Since we were asked to have a single cycle we set the first argument of CYCLE to 1 and obtain CYCLE(1, (1 $S_1$, 2 $S_2$, 3 $S_3$, 4 $S_4$, 5 $S_5$, 6 $S_6$)).

C. Since there is a single cycle, $S_i \neq i$ (with $i \in [1, 6]$).

A necessary condition for the CYCLE constraint is that all its successor variables are assigned distinct values, i.e. each vertex has exactly one predecessor in a ground solution. Consequently, infeasible variable-value pairs for ALLDIFFERENT are also infeasible for CYCLE. Any edge that does not belong to a matching of cardinality 6 in the corresponding variable-value graph $G_{val}$ given on the right can not be part of a solution. As a result $G'$ is shown below on the right.

We now deal with the fact that we should have a single cycle. A necessary condition is that the graph $G'$ consists of a single strongly connected component. We identify the arcs $u \rightarrow v$ of $G'$ such that, if they were removed, the number of strongly connected components of $G'$ would be greater than one. For such arcs $u \rightarrow v$ we remove all arcs $w \rightarrow v$ (with $w \neq u$).

- If we remove 1 $\rightarrow$ 6 from $G'$ we obtain $G'_{1\rightarrow6}$ which has the two strongly connected components depicted by the two blue rectangles. Consequently the arc 5 $\rightarrow$ 6 is forbidden.

- If we remove 5 $\rightarrow$ 2 from $G'$ we obtain $G'_{5\rightarrow2}$ which has the two strongly connected components depicted by the two blue rectangles. Consequently the arc 1 $\rightarrow$ 2 is forbidden.

As a consequence we have a unique solution $S_1 = 6$, $S_2 = 4$, $S_3 = 1$, $S_4 = 3$, $S_5 = 2$, $S_6 = 5$ corresponding to the Hamiltonian cycle $1 \leftrightarrow 6 \leftrightarrow 5 \leftrightarrow 2 \leftrightarrow 4 \leftrightarrow 3 \leftrightarrow 1$. 
SOLUTION TO EXERCISE 4

A.  (a) The variable-based degree of violation is equal to 1 since the 
ALLDIFFERENT constraint holds and since we just have to correct the 
number of cycles (we have the two cycles $1 \rightarrow 2 \rightarrow 3 \rightarrow 1$ and $4 \rightarrow 4$ 
rather than one cycle). Therefore we only need to set the first argument 
of the CYCLE constraint to 2.

   CYCLE(2, (1, 2, 3, 3, 1, 4, 4))

   (b) Since we have two occurrences of 3 and two occurrences of 4 in the 
successor variables the variable-based degree of violation is at least 
equal to 2. Since, as shown below, it is possible the building of a single 
cycle $1 \rightarrow 3 \rightarrow 2 \rightarrow 4 \rightarrow 1$ by just changing the assignment of two 
variables, the variable-based degree of violation is equal to 2.

   CYCLE(1, (1, 3, 2, 4, 3, 3, 4, 4))

   (c) Since we have two occurrences of 2 and two occurrences of 4 in the 
successor variables the variable-based degree of violation is at least 
equal to 2. Since just changing the values of two successor variables 
does not allow the building of 6 cycles the variable-based degree of 
vViolation is at least equal to 3. It is equal to 3 as shown by the 
following assignment that corresponds to the three cycles $1 \rightarrow 2 \rightarrow 1$, 
$3 \rightarrow 4 \rightarrow 3$, $5 \rightarrow 6 \rightarrow 5$.

   CYCLE(6, (1, 2, 2, 3, 4, 4, 5, 6, 5))

B.  Within the graph associated with the CYCLE constraint let nCycle, nMap and 
source respectively denote the number of connected components 
corresponding to a single cycle, the number of connected components with at 
least one source, and the number of sources.

   Given N the first argument of the CYCLE constraint the variable-based degree 
of violation is equal to nSource + δ where δ is equal to 0 if 
N ∈ [nCycle + (nMap > 0), nCycle + nMap] and 1 otherwise. The idea is 
that we have to change at least nSource successor variables to fulfil the 
ALLDIFFERENT constraint, and possibly the first argument N if we can not 
reach N cycles by just changing nSource successor variables. The figures 
below illustrate the formula for the three examples of the previous question:

   (a) We have $0 + 4 \not\in [2 + (0 > 0), 2 + 0] = 1$,

   (b) We have $2 + 1 \not\in [0 + (2 > 0), 0 + 2] = 2$,

   (c) We have $2 + 6 \not\in [1 + (2 > 0), 1 + 2] = 3$. 

\[\begin{align*}
\text{ncycle} &= 2 \\
\text{nmap} &= 0 \\
\text{source} &= 0 \\
\text{(a)} &
\end{align*}\]
SOLUTION TO EXERCISE 5

A. A De Bruijn sequence of order \( m \) over an alphabet \( A = \{0, 1, \ldots, n - 1\} \) can be seen as a Hamiltonian cycle\(^a\) on the De Bruijn digraph of order \( m \) defined over the same alphabet \( A \), where the sequence of letters corresponds to the sequence of last letters of the words associated with the successive vertices of the cycle. Visiting once each vertex of the digraph allows the corresponding cyclic sequence to contain exactly once each word of length \( m \) of the alphabet \( A \).

![De Bruijn digraph of order 3 over \( A = \{0, 1\} \)](image)

A De Bruijn sequence of order 3 over \( A = \{0, 1\} \)

B. Each vertex of the De Bruijn graph associated with a word \( w \) is labelled by the decimal number plus one\(^b\) corresponding to \( w \). Then to each vertex of the De Bruijn graph corresponds a successor variable whose initial domain is set to the labels of the successors of \( v \). Finally a CYCLE constraint with one cycle is posted.

\[
\begin{align*}
S_1 & \in \{1, 2\}, \quad S_2 \in \{3, 4\}, \quad S_3 \in \{5, 6\}, \quad S_4 \in \{7, 8\}, \\
S_5 & \in \{1, 2\}, \quad S_6 \in \{3, 4\}, \quad S_7 \in \{5, 6\}, \quad S_8 \in \{7, 8\}, \\
\text{CYCLE} & (1, (1S_1, 2S_2, 3S_3, 4S_4, 5S_5, 6S_6, 7S_7, 8S_8)).
\end{align*}
\]

A solution corresponds to the sequence \((S_1 - 1) \mod n, (S_2 - 1) \mod n, \ldots, (S_8 - 1) \mod n\).

\(^a\)Given a digraph \( G \) with \( p \) vertices, a Hamiltonian cycle of \( G \) is a succession of arcs \( v_1 \rightarrow v_2, v_2 \rightarrow v_3, \ldots, v_{p-1} \rightarrow v_p, v_p \rightarrow v_1 \) of \( G \) such that the vertices \( v_1, v_2, \ldots, v_p \) are all distinct.

\(^b\)1 since, within the CYCLE constraint, vertices are labelled from 1 up to the total number of vertices.
## 5.106 CYCLE_CARD_ON_PATH

**CHIP**

**Constraint**

\[
\text{NCYCLE} : \text{dvar} \\
\text{NODES} : \text{collection}([\text{index} - \text{int}, \text{succ} - \text{dvar}, \text{colour} - \text{dvar}]) \\
\text{ATLEAST} : \text{int} \\
\text{ATMOST} : \text{int} \\
\text{PATH\_LEN} : \text{int} \\
\text{VALUES} : \text{collection}([\text{val} - \text{int}])
\]

**Arguments**

- \(\text{NCYCLE} \geq 1\)
- \(\text{NCYCLE} \leq |\text{NODES}|\)
- \(\text{required}(\text{NODES}, [\text{index}, \text{succ}, \text{colour}])\)
- \(\text{NODES}.\text{index} \geq 1\)
- \(\text{NODES}.\text{index} \leq |\text{NODES}|\)
- \(\text{distinct}(\text{NODES}, \text{index})\)
- \(\text{NODES}.\text{succ} \geq 1\)
- \(\text{NODES}.\text{succ} \leq |\text{NODES}|\)
- \(\text{ATLEAST} \geq 0\)
- \(\text{ATLEAST} \leq \text{PATH\_LEN}\)
- \(\text{ATMOST} \geq \text{ATLEAST}\)
- \(\text{PATH\_LEN} \geq 0\)
- \(|\text{VALUES}| \geq 1\)
- \(\text{required}(\text{VALUES}, \text{val})\)
- \(\text{distinct}(\text{VALUES}, \text{val})\)

**Purpose**

Consider a digraph \(G\) described by the \text{NODES} collection. \text{NCYCLE} is the number of circuits for covering \(G\) in such a way that each vertex belongs to a single circuit. In addition the following constraint must also hold: on each set of \text{PATH\_LEN} consecutive distinct vertices of each final circuit, the number of vertices for which the attribute colour takes his value in the collection of values \text{VALUES} should be located within the range \([\text{ATLEAST}, \text{ATMOST}]\).

**Example**

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} - 7 & \text{colour} - 2, \\
\text{index} - 2 & \text{succ} - 4 & \text{colour} - 3, \\
\text{index} - 3 & \text{succ} - 8 & \text{colour} - 2, \\
\text{index} - 4 & \text{succ} - 9 & \text{colour} - 1, \\
2, & \text{index} - 5 & \text{succ} - 1 & \text{colour} - 2, \\
\text{index} - 6 & \text{succ} - 2 & \text{colour} - 1, \\
\text{index} - 7 & \text{succ} - 5 & \text{colour} - 1, \\
\text{index} - 8 & \text{succ} - 6 & \text{colour} - 1, \\
\text{index} - 9 & \text{succ} - 3 & \text{colour} - 1
\end{pmatrix}
\]

\(\langle 1 \rangle\)
Figure 5.254 illustrates the example with its corresponding circuits and all their sliding sequences of three consecutive vertices. The constraint `CYCLE_CARD_ON_PATH` holds since the vertices of the `NODES` collection correspond to a set of disjoint circuits and since, for each set of 3 (i.e., `PATH_LEN = 3`) consecutive vertices, colour 1 (i.e., the value provided by the `VALUES` collection) occurs at least once (i.e., `ATLEAST = 1`) and at most twice (i.e., `ATMOST = 2`).

![Diagram of circuits and sliding sequences](https://via.placeholder.com/150)

**Figure 5.254:** The two circuits (bottom) and all the corresponding sliding sequences of three consecutive vertices, where an occurrence of colour 1 is represented by a tiny circle (top) of the `Example` slot

Parts (A) and (B) of Figure 5.255 respectively show the initial and final graph associated with the Example slot. Since we use the NCC graph property, we show the two connected components of the final graph. The constraint CYCLE_CARD_ON_PATH holds since all the vertices belong to a circuit (i.e., NTREE = 0) and since for each set of three consecutive vertices, colour 1 occurs at least once and at most twice (i.e., the AMONG_LOW_UP constraint holds).

5.107 CYCLE_OR_ACCESSIBILITY

<table>
<thead>
<tr>
<th>DESCRIPTION</th>
<th>LINKS</th>
<th>GRAPH</th>
</tr>
</thead>
</table>

Origin
Inspired by [255].

Constraint
CYCLE_OR_ACCESSIBILITY(MAXDIST, NCYCLE, NODES)

Arguments
- MAXDIST : int
- NCYCLE : dvar
- NODES : collection(index-int, succ-dvar, x-int, y-int)

Restrictions
- MAXDIST ≥ 0
- NCYCLE ≥ 1
- NCYCLE ≤ |NODES|
- required(NODES,[index,succ,x,y])
- NODES.index ≥ 1
- NODES.index ≤ |NODES|
- distinct(NODES,index)
- NODES.succ ≥ 0
- NODES.succ ≤ |NODES|
- NODES.x ≥ 0
- NODES.y ≥ 0

Purpose
Consider a digraph $G$ described by the NODES collection. Cover a subset of the vertices of $G$ by a set of vertex-disjoint circuits in such a way that the following property holds: for each uncovered vertex $v_1$ of $G$ there exists at least one covered vertex $v_2$ of $G$ such that the Manhattan distance between $v_1$ and $v_2$ is less than or equal to MAXDIST.

Example

<tr>
<td>index - 7</td>
</tr>
</tbody>
</table>

Figure 5.256 represents the solution associated with the example. The covered vertices are coloured in blue, while the links starting from the uncovered vertices are dashed. The CYCLE_OR_ACCESSIBILITY constraint holds since:
- In the solution we have NCYCLE = 2 disjoint circuits.
- All the 3 uncovered nodes are located at a distance that does not exceed MAXDIST = 3 from at least one covered node.

Typical
- MAXDIST > 0
- NCYCLE < |NODES|
- |NODES| > 2
Figure 5.256: Final graph associated with the facilities location problem

Symmetries
- Items of NODES are permutable.
- Attributes of NODES are permutable w.r.t. permutation (index) (\textit{succ}) \( (x, y) \) (permutation applied to all items).
- One and the same constant can be added to the \( x \) attribute of all items of NODES.
- One and the same constant can be added to the \( y \) attribute of all items of NODES.

Arg. properties
Functional dependency: \( NCYCLE \) determined by NODES.

Remark
This kind of facilities location problem is described in [255, pages 187–189] pages. In addition to our example they also mention the cost problem that is usually a trade-off between the vertices that are directly covered by circuits and the others.

\]
Constraint(s) on sets NVALUES_EXCEPT_0(variables,=,1)

Graph model
For each vertex \( v \) we have introduced the following attributes:

- index: the label associated with \( v \),
- succ: if \( v \) is not covered by a circuit then 0; If \( v \) is covered by a circuit then index of the successor of \( v \).
- x: the x-coordinate of \( v \),
- y: the y-coordinate of \( v \).

The first graph constraint forces all vertices, which have a non-zero successor, to form a set of NCYCLE vertex-disjoint circuits.

The final graph associated with the second graph constraint contains two types of arcs:

- The arcs belonging to one circuit (i.e., nodes1.succ = nodes2.index),
- The arcs between one vertex \( v_1 \) that does not belong to any circuit (i.e., nodes1.succ = 0) and one vertex \( v_2 \) located on a circuit (i.e., nodes2.succ \( \neq 0 \)) such that the Manhattan distance between \( v_1 \) and \( v_2 \) is less than or equal to MAXDIST.

In order to specify the fact that each vertex is involved in at least one arc we use the graph property NVERTEX = |NODES|. Finally the dynamic constraint NVALUES_EXCEPT_0(variables,=,1) expresses the fact that, for each vertex \( v \), there is exactly one predecessor of \( v \) that belongs to a circuit.
Parts (A) and (B) of Figure 5.257 respectively show the initial and final graph associated with the second graph constraint of the Example slot.

Figure 5.257: Initial and final graph of the CYCLE_OR_ACCESSIBILITY constraint

**Signature**

Since $|\text{NODES}|$ is the maximum number of vertices of the final graph associated with the second graph constraint we can rewrite $\text{NVERTEX} = |\text{NODES}|$ to $\text{NVERTEX} \geq |\text{NODES}|$. This leads to simplify $\text{NVERTEX}$ to $\text{NVERTEX}$. 
5.108 CYCLE_RESOURCE

Origin
CHIP

Constraint
CYCLE_RESOURCE(RESOURCE, TASK)

Arguments
RESOURCE : collection(id=int, first_task=dvar, nb_task=dvar)
TASK : collection(id=int, next_task=dvar, resource=dvar)

Restrictions
required(RESOURCE, [id, first_task, nb_task])
RESOURCE.id ≥ 1
RESOURCE.id ≤ |RESOURCE|
distinct(RESOURCE, id)
RESOURCE.first_task ≥ 1
RESOURCE.first_task ≤ |RESOURCE| + |TASK|
RESOURCE.nb_task ≥ 0
RESOURCE.nb_task ≤ |TASK|
required(TASK, [id, next_task, resource])
TASK.id > |RESOURCE|
TASK.id ≤ |RESOURCE| + |TASK|
distinct(TASK, id)
TASK.next_task ≥ 1
TASK.next_task ≤ |RESOURCE| + |TASK|
TASK.resource ≥ 1
TASK.resource ≤ |RESOURCE|

Purpose
Consider a digraph $G$ defined as follows:

- To each item of the RESOURCE and TASK collections corresponds one vertex of $G$. A vertex that was generated from an item of the RESOURCE (respectively TASK) collection is called a resource vertex (respectively task vertex).
- There is an arc from a resource vertex $r$ to a task vertex $t$ if $t \in$ RESOURCE[$r$].first_task.
- There is an arc from a task vertex $t$ to a resource vertex $r$ if $r \in$ TASK[$t$].next_task.
- There is an arc from a task vertex $t_1$ to a task vertex $t_2$ if $t_2 \in$ TASK[$t_1$].next_task.
- There is no arc between two resource vertices.

Enforce to cover $G$ in such a way that each vertex belongs to a single circuit. Each circuit is made up from a single resource vertex and zero, one or more task vertices. For each resource-vertex a domain variable indicates how many task-vertices belong to the corresponding circuit. For each task a domain variable provides the identifier of the resource that can effectively handle that task.
Example

The `CYCLE RESOURCE` constraint holds since the graph corresponding to the vertices described by its arguments consists of the following 3 disjoint circuits:

- The first circuit involves the `resource` vertex 1 as well as the `task` vertices 5, 4 and 7.
- The second circuit is limited to the `resource` vertex 2.
- Finally the third circuit is made up from the remaining vertices, namely the `resource` vertex 3 and the `task` vertices 8 and 6.

Typical

| RESOURCE | > 1 |
| TASK | > 1 |
| TASK | > | RESOURCE |

Symmetries

- Items of `RESOURCE` are permutable.
- Items of `TASK` are permutable.
- All occurrences of two distinct values in `RESOURCE.id` or `TASK.resource` can be swapped.

Usage

This constraint is useful for some vehicles routing problem where the number of locations to visit depends of the vehicle type that is actually used. The resource attribute allows expressing various constraints such as:

- The compatibility or incompatibility between tasks and vehicles,
- The fact that certain tasks should be performed by the same vehicle,
- The pre-assignment of certain tasks to a given vehicle.

Remark

This constraint could be expressed with the `CYCLE` constraint of `CHIP` by using the following optional parameters:

- The `resource node` parameter [93, page 97],
- The `circuit weight` parameter [93, page 101],
- The `name` parameter [93, page 104].

See also

- \( \text{resource_task1.name} = \text{RESOURCE.id} \)

#### Graph property(ies)
- \( \text{NVERTEX} = \text{RESOURCE.nb_task} + 1 \)

#### Graph model
The graph model of the CYCLERESOURCE constraint illustrates the following points:

- How to differentiate the constraint on the length of a circuit according to a resource that is assigned to a circuit? This is achieved by introducing a collection of resources and by asking a different graph property for each item of that collection.

- How to introduce the concept of name that corresponds to the resource that handles a given task? This is done by adding to the arc constraint associated with the CYCLE constraint the condition that the name variables of two consecutive vertices should be equal.

Part (A) of Figure 5.258 shows the initial graphs (of the second graph constraint) associated with resources 1, 2 and 3 of the Example slot. Part (B) of Figure 5.258 shows the corresponding final graphs (of the second graph constraint) associated with resources 1, 2 and 3.
Since we use the \texttt{NVERTEX} graph property, the vertices of the final graphs are stressed in bold. To each resource corresponds a circuit of respectively 3, 0 and 2 task-vertices.

Figure 5.258: Initial and final graph of the \texttt{CYCLE\_RESOURCE} constraint

\textbf{Signature}

Since the initial graph of the first graph constraint contains $|\text{RESOURCE}| + |\text{TASK}|$ vertices, the corresponding final graph cannot have more than $|\text{RESOURCE}| + |\text{TASK}|$ vertices. Therefore we can rewrite the graph property $\text{NVERTEX} = |\text{RESOURCE}| + |\text{TASK}|$ to $\text{NVERTEX} \geq |\text{RESOURCE}| + |\text{TASK}|$ and simplify $\text{NVERTEX}$ to $\text{NVERTEX}$. 
5.109  CYCLIC_CHANGE

<table>
<thead>
<tr>
<th>DESCRIPTION</th>
<th>LINKS</th>
<th>GRAPH</th>
<th>AUTOMATON</th>
</tr>
</thead>
<tbody>
<tr>
<td>Origin</td>
<td>Derived from CHANGE.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Constraint</td>
<td>CYCLIC_CHANGE(NCHANGE, CYCLE_LENGTH, VARIABLES, CTR)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Arguments   | NCHANGE : dvar  
CYCLE_LENGTH : int  
VARIABLES : collection(var−dvar)  
CTR : atom |
| Restrictions| NCHANGE ≥ 0  
NCHANGE < |VARIABLES|  
CYCLE_LENGTH > 0  
required(VARIABLES, var)  
VARIABLES.var ≥ 0  
VARIABLES.var < CYCLE_LENGTH  
CTR ∈ [=, ≠, <, ≥, >, ≤] |
| Purpose     | NCHANGE is the number of times that constraint \((X + 1) \mod CYCLE_LENGTH\) CTR \(Y\) holds; \(X\) and \(Y\) correspond to consecutive variables of the collection VARIABLES. |
| Example     | \((2, 4, \langle 3, 0, 2, 3, 1 \rangle, ≠)\) |
|             | Since CTR is set to ≠ and since CYCLE_LENGTH is set to 4, a change between two consecutive items \(X\) and \(Y\) of the VARIABLES collection corresponds to the fact that the condition \((X + 1) \mod 4\) ≠ \(Y\) holds. Consequently, the CYCLIC_CHANGE constraint holds since we have the two following changes (i.e., NCHANGE = 2) within \(\langle 3, 0, 2, 3, 1 \rangle\): |
|             | • A first change between the consecutive values 0 and 2,  
|             | • A second change between the consecutive values 3 and 1. |
|             | However, the sequence 3 0 does not correspond to a change since \((3 + 1) \mod 4\) is equal to 0. |
| Typical     | NCHANGE > 0  
|             | \(|VARIABLES| > 1\)  
|             | \(range(VARIABLES.var) > 1\)  
|             | CTR ∈ [≠] |
| Symmetry    | Items of VARIABLES can be shifted. |
| Arg. properties | Functional dependency: NCHANGE determined by CYCLE_LENGTH, VARIABLES and CTR. |
This constraint may be used for personnel cyclic timetabling problems where each person has to work according to cycles. In this context each variable of the VARIABLES collection corresponds to the type of work a person performs on a specific day. Because of some perturbation (e.g., illness, unavailability, variation of the workload) it is in practice not reasonable to ask for perfect cyclic solutions. One alternative is to use the CYCLIC_CHANGE constraint and to ask for solutions where one tries to minimise the number of cycle breaks (i.e., the variable NCHANGE).

• BIPARTITE
• NO LOOP

Graph model

Parts (A) and (B) of Figure 5.259 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold.

Figure 5.259: Initial and final graph of the CYCLIC_CHANGE constraint
Figure 5.260 depicts the automaton associated with the CYCLIC_CHANGE constraint. To each pair of consecutive variables (VAR_i, VAR_{i+1}) of the collection VARIABLES corresponds a 0-1 signature variable S_i. The following signature constraint links VAR_i, VAR_{i+1} and S_i:

\[
((VAR_i + 1) \mod CYCLE\_LENGTH) \quad \text{CTR VAR}_{i+1} \iff S_i.
\]

\[
\{C \leftarrow 0\} \quad \quad ((VAR_i + 1) \mod CYCLE\_LENGTH) \quad \text{CTR VAR}_{i+1}, \quad \{C \leftarrow C + 1\}
\]

NCHANGE = C

Figure 5.260: Automaton of the CYCLIC_CHANGE constraint

Figure 5.261: Hypergraph of the reformulation corresponding to the automaton of the CYCLIC_CHANGE constraint
5.110 CYCLIC_CHANGE_JOKER

Origin
Derived from CYCLIC_CHANGE.

Constraint
CYCLIC_CHANGE_JOKER(NCHANGE, CYCLE_LENGTH, VARIABLES, CTR)

Arguments
- NCHANGE : dvar
- CYCLE_LENGTH : int
- VARIABLES : collection(var−dvar)
- CTR : atom

Restrictions
- NCHANGE ≥ 0
- NCHANGE < |VARIABLES|
- CYCLE_LENGTH > 0
- required(VARIABLES, var)
- VARIABLES.var ≥ 0
- CTR ∈ [=, ≠, <, ≥, >, ≤]

Purpose
NCHANGE is the number of times that the following constraint holds:

\[ ((X + 1) \mod CYCLE_LENGTH) \land Y < CYCLE_LENGTH \land Y < CYCLE_LENGTH \]

X and Y correspond to consecutive variables of the collection VARIABLES.

Example
\((2, 4, \langle 3, 0, 2, 4, 4, 3, 1, 4 \rangle, \neq)\)

Since CTR is set to ≠ and since CYCLE_LENGTH is set to 4, a change between two consecutive items X and Y of the VARIABLES collection corresponds to the fact that the condition \(((X + 1) \mod 4) \neq Y \land X < 4 \land Y < 4\) holds. Consequently, the CYCLIC_CHANGE_JOKER constraint holds since we have the two following changes (i.e., NCHANGE = 2) within \(\langle 3, 0, 2, 4, 4, 3, 1, 4 \rangle\):

- A first change between 0 and 2,
- A second change between 3 and 1.

But when the joker value 4 is involved, there is no change. This is why no change is counted between values 2 and 4, between 4 and 4 and between 1 and 4.

Typical
- NCHANGE > 0
- CYCLE_LENGTH > 1
- |VARIABLES| > 1
- range(VARIABLES.var) > 1
- maxval(VARIABLES.var) ≥ CYCLE_LENGTH
- CTR ∈ [≠]
**Typical model**

| **ATLEAST(2, VARIABLES, 0)** |

**Symmetry**

Items of VARIABLES can be shifted.

**Arg. properties**

Functional dependency: \( NCHANGE \) determined by CYCLE_LENGTH, VARIABLES and CTR.

**Usage**

The CYCLIC_CHANGE_JOKER constraint can be used in the same context as the CYCLIC_CHANGE constraint with the additional feature: in our example codes 0 to 3 correspond to different type of activities (i.e., working the morning, the afternoon or the night) and code 4 represents a holiday. We want to express the fact that we do not count any change for two consecutive days \( d_1, d_2 \) such that \( d_1 \) or \( d_2 \) is a holiday.

**See also**

- common keyword: CHANGE, CYCLIC_CHANGE (number of changes).

- constraint arguments: pure functional dependency.
- constraint network structure: sliding cyclic(1) constraint network(2).
- constraint type: timetabling constraint.
- final graph structure: acyclic, bipartite, no loop.
- modelling: number of changes, functional dependency.
Arc input(s) | VARIABLES
---|---
Arc generator | \( PATH \rightarrow \text{collection}(\text{variables1, variables2}) \)
Arc arity | 2
Arc constraint(s) | • \((\text{variables1}.\text{var} + 1) \mod \text{CYCLE_LENGTH} \) \text{CTR} \text{variables2}.\text{var}
• \text{variables1}.\text{var} < \text{CYCLE_LENGTH}
• \text{variables2}.\text{var} < \text{CYCLE_LENGTH}
Graph property(ies) | \text{NARC} = \text{NCHANGE}
Graph class | • \text{ACYCLIC}
• \text{BIPARTITE}
• \text{NO_LOOP}

Graph model

The \textit{joker values} are those values that are greater than or equal to \text{CYCLE_LENGTH}. We do not count any change for those arc constraints involving at least one variable taking a joker value.

Parts (A) and (B) of Figure 5.262 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the \textbf{NARC} graph property, the arcs of the final graph are stressed in bold.

![Initial and final graph of the CYCLIC\_CHANGE\_JOKER constraint](image)

Figure 5.262: Initial and final graph of the \textit{CYCLIC\_CHANGE\_JOKER} constraint
Automaton

Figure 5.263 depicts the automaton associated with the CYCLIC_CHANGE_JOKER constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection VARIABLES corresponds a 0-1 signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i\), \(\text{VAR}_{i+1}\) and \(S_i\):

\[
((\text{VAR}_i + 1) \mod \text{CYCLE\_LENGTH}) \land \text{CTR} \land \text{VAR}_{i+1} \land (\text{VAR}_i < \text{CYCLE\_LENGTH}) \land (\text{VAR}_{i+1} < \text{CYCLE\_LENGTH}) \Leftrightarrow S_i.
\]

\begin{align*}
((\text{VAR}_i + 1) \mod \text{CYCLE\_LENGTH}) &\not\land \text{CTR} \land \text{VAR}_{i+1} \lor \\
\text{VAR}_i &\geq \text{CYCLE\_LENGTH} \lor \text{VAR}_{i+1} \geq \text{CYCLE\_LENGTH}
\end{align*}

\(\{C \leftarrow 0\} \quad \text{NCHANGE} = C \quad \{C \leftarrow C + 1\}

Figure 5.264: Hypergraph of the reformulation corresponding to the automaton of the CYCLIC_CHANGE_JOKER constraint
## 5.111 DAG

### Origin

[151]

### Constraint

DAG(NODES)

### Argument

\[
\text{NODES} : \text{collection}(\text{index} - \text{int}, \text{succ} - \text{svar})
\]

### Restrictions

\[
\begin{align*}
\text{required} & (\text{NODES}, [\text{index}, \text{succ}]) \\
\text{NODES}.\text{index} & \geq 1 \\
\text{NODES}.\text{index} & \leq |\text{NODES}| \\
\text{distinct} & (\text{NODES}, \text{index}) \\
\text{NODES}.\text{succ} & \geq 1 \\
\text{NODES}.\text{succ} & \leq |\text{NODES}|
\end{align*}
\]

### Purpose

Consider a digraph \( G \) described by the NODES collection. Select a subset of arcs of \( G \) so that the corresponding graph does not contain any circuit.

### Example

\[
\begin{cases}
\text{index} - 1 \quad \text{succ} - \{2, 4\}, \\
\text{index} - 2 \quad \text{succ} - \{3, 4\}, \\
\text{index} - 3 \quad \text{succ} - 0, \\
\text{index} - 4 \quad \text{succ} - 0, \\
\text{index} - 5 \quad \text{succ} - \{6\}, \\
\text{index} - 6 \quad \text{succ} - 0
\end{cases}
\]

The DAG constraint holds since the NODES collection depicts a graph without circuit.

### Typical

\(|\text{NODES}| > 2|

### Symmetry

Items of NODES are permutable.

### Algorithm

A filtering algorithm for the DAG constraint is given in [151, page 90]. It removes potential arcs that would create a circuit of mandatory arcs.

### See also

used in graph description: IN_SET.

### Keywords

constraint arguments: constraint involving set variables.

constraint type: graph constraint.
Arc input(s) NODES
Arc generator $SELF \mapsto \text{collection}(\text{nodes})$
Arc arity 1
Arc constraint(s) $\text{IN\_SET}(\text{nodes}.\text{key}, \text{nodes}.\text{succ})$
Graph property(ies) $\text{NARC} = 0$

Arc input(s) NODES
Arc generator $\text{CLIQUE} \mapsto \text{collection}(\text{nodes1}, \text{nodes2})$
Arc arity 2
Arc constraint(s) $\text{IN\_SET}(\text{nodes2}.\text{index}, \text{nodes1}.\text{succ})$
Graph property(ies) $\text{MAX\_NSCC} \leq 1$

Graph model

The first graph constraint removes the loop of each vertex. The second graph constraint forbids the creation of circuits involving more than one vertex.

Part (A) of Figure 5.265 shows the initial graph associated with the second graph constraint of the Example slot. This initial graph from which we start is derived from the set associated with each vertex. Each set describes the potential values of the $\text{succ}$ attribute of a given vertex. Part (B) of Figure 5.265 gives the final graph associated with the Example slot.

Figure 5.265: Initial and final graph of the DAG set constraint
5.12 DECREASING

Origin
Inspired by INCREASING.

Constraint
DECREASING(VARIABLES)

Argument
VARIABLES : collection(var–dvar)

Restriction
required(VARIABLES, var)

Purpose
The variables of the collection VARIABLES are decreasing.

Example
\( ((8, 4, 1, 1)) \)

The DECREASING constraint holds since \( 8 \geq 4 \geq 1 \geq 1 \).

Typical
\(|\text{VARIABLES}| > 2\)
\(\text{range(}\text{VARIABLES.var}\text{)} > 1\)

Typical model
\(\text{nval(}\text{VARIABLES.var}\text{)} > 2\)

Symmetry
One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties
Contractible wrt. VARIABLES.

### 5.113 DECREASING\_PEAK

**Origin**
Derived from PEAK and DECREASING.

**Constraint**
DECREASING\_PEAK(VARIABLES)

**Argument**
VARIABLES : collection(var−dvar)

**Restrictions**
|VARIABLES| > 0
required(VARIABLES, var)

A variable $V_k (1 < k < m)$ of the sequence of variables $V_1, \ldots, V_m$ is a peak if and only if there exists an $i (1 < i \leq k)$ such that $V_{i-1} < V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k > V_{k+1}$.

**Purpose**
When considering all the peaks of the sequence $VARIABLES$ from left to right enforce all peaks to be decreasing, i.e. the altitude of each peak is less than or equal to the altitude of its preceding peak when it exists.

**Example**

$((1, 7, 7, 4, 3, 7, 2, 2, 5, 4))$

The DECREASING\_PEAK constraint holds since the sequence $1 \ 7 \ 7 \ 4 \ 3 \ 7 \ 2 \ 2 \ 5 \ 4$ contains three peaks, in bold, that are decreasing.

![Figure 5.269: Illustration of the Example slot: a sequence of ten variables $V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10}$ respectively fixed to values 1, 7, 7, 4, 3, 7, 2, 2, 5, 4 and its corresponding three peaks, in red, respectively located at altitudes 7, 7 and 5](image-url)
Typical

| VARIABLES | ≥ 7  

range(VARIABLES.var) > 1

PEAK(VARIABLES.var) ≥ 3

Typical model

nval(VARIABLES.var) > 2

Symmetry

One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties

- Prefix-contractible wrt. VARIABLES.
- Suffix-contractible wrt. VARIABLES.

5.115 DEEPEST_VALLEY

**Origin**
Derived from VALLEY.

**Constraint**
DEEPEST_VALLEY(DEPTH, VARIABLES)

**Arguments**
- DEPTH : dvar
- VARIABLES : collection(var–dvar)

**Restriction**
required(VARIABLES, var)

**Purpose**
A variable $V_k$ ($1 < k < m$) of the sequence of variables VARIABLES = $V_1, \ldots, V_m$ is a valley if and only if there exists an $i$ ($1 < i \leq k$) such that $V_{i-1} > V_i$ and $V_i = V_{i+1} = \cdots = V_k$ and $V_k < V_{k+1}$. DEPTH is the minimum value of the valley variables. If no such variable exists DEPTH is equal to the default value MAXINT.

**Example**
(2, (5, 3, 4, 8, 8, 2, 7, 1))
(7, (1, 3, 4, 8, 8, 7, 8))

The first DEEPEST_VALLEY constraint holds since 2 is the deepest valley of the sequence 5 3 4 8 8 2 7 1.

Figure 5.275: Illustration of the first example of the Example slot: a sequence of eight variables $V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8$ respectively fixed to values 5, 3, 4, 8, 8, 2, 7, 1 and its corresponding deepest valley of depth 2

**Typical**
- $|\text{VARIABLES}| > 2$
- range(VARIABLES.var) > 2
- VALLEY(VARIABLES.var) > 0
Typical model \( nval(VARIABLES\cdot var) > 2 \)

Symmetry Items of VARIABLES can be reversed.

Arg. properties Functional dependency: DEPTH determined by VARIABLES.

Counting

Solution count for DEEPEST_VALLEY: domains 0..n
Solution density for DEEPEST_VALLEY

Parameter value as fraction of length

Observed density

Solution density for DEEPEST_VALLEY

Parameter value as fraction of length

Observed density

See also common keyword: HIGHEST_PEAK, VALLEY (sequence).
implies: BETWEEN_MIN_MAX.
Keywords

characteristic of a constraint: maxint, automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

c constraint arguments: reverse of a constraint, pure functional dependency.

c constraint network structure: sliding cyclic(1) constraint network(2).

filtering: glue matrix.

modelling: functional dependency.
Automaton

Figure 5.276 depicts the automaton associated with the DEEPEST_VALLEY constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection VARIABLES corresponds a signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i, \text{VAR}_{i+1}\) and \(S_i\):

\[
\text{VAR}_i < \text{VAR}_{i+1} \iff S_i = 0 \land \text{VAR}_i = \text{VAR}_{i+1} \iff S_i = 1 \land \text{VAR}_i > \text{VAR}_{i+1} \iff S_i = 2.
\]

**STATE SEMANTICS**

- \(s\) : stationary/increasing mode \(\{< | =\}^*\)
- \(u\) : decreasing mode \(\{> | =\}^*\)

Glue matrix where \(\vec{C}\) and \(\vec{C}\) resp. represent the counters values \(C\) at the end of a prefix and at the end of the corresponding reverse suffix that partitions the sequence VARIABLES; \(X\) denotes the last variable of the prefix.

\[
\begin{array}{c|c|c}
\text{s} & \text{C} & \text{u} \\
\text{VAR}_i = \text{VAR}_{i+1} & \{C \leftarrow \text{maxint}\} & \text{VAR}_i < \text{VAR}_{i+1} \\
\text{VAR}_i > \text{VAR}_{i+1} & \{C \leftarrow \min(C, \text{VAR}_i)\} & \text{VAR}_i = \text{VAR}_{i+1} \\
\text{VAR}_i = \text{VAR}_{i+1} & \{C \leftarrow \min(C, \text{VAR}_i)\} & \text{VAR}_i > \text{VAR}_{i+1}
\end{array}
\]

Figure 5.276: Automaton of the DEEPEST_VALLEY constraint and its glue matrix (state \(s\) means that we are in increasing or stationary mode, state \(u\) means that we are in decreasing mode, a new valley is detected each time we switch from decreasing to increasing mode and the counter \(C\) is updated accordingly); maxint is the largest integer that can be represented on a machine.

Figure 5.277: Hypergraph of the reformulation corresponding to the automaton of the DEEPEST_VALLEY constraint (\(C_0\) is set to maxint the largest integer that can be represented on a machine)
### 5.116 DERANGEMENT

**Origin**

Derived from `CYCLE`.

**Constraint**

`DERANGEMENT(NODES)`

**Argument**

`NODES : collection(index=int, succ=dvar)`

**Restrictions**

- `|NODES| > 1`
- `required(NODES,[index, succ])`
- `NODES.index ≥ 1`
- `NODES.index ≤ |NODES|`
- `distinct(NODES,index)`
- `NODES.succ ≥ 1`
- `NODES.succ ≤ |NODES|`

**Purpose**

Enforce to have a permutation with no cycle of length one. The permutation is depicted by the `succ` attribute of the `NODES` collection.

**Example**

\[
\begin{pmatrix}
  \text{index} - 1 & \text{succ} - 2, \\
  \text{index} - 2 & \text{succ} - 1, \\
  \text{index} - 3 & \text{succ} - 5, \\
  \text{index} - 4 & \text{succ} - 3, \\
  \text{index} - 5 & \text{succ} - 4
\end{pmatrix}
\]

In the permutation of the example we have the following 2 cycles: \(1 \rightarrow 2 \rightarrow 1\) and \(3 \rightarrow 5 \rightarrow 4 \rightarrow 3\). Since these cycles have both a length strictly greater than one the corresponding DERANGEMENT constraint holds.

**All solutions**

Figure 5.278 gives all solutions to the following non ground instance of the DERANGEMENT constraint: \(S_1 \in [2, 4], S_2 \in [1, 2], S_3 \in [1, 4], S_4 \in [2, 4],\) `DERANGEMENT((1 \ S_1, 2 \ S_2, 3 \ S_3, 4 \ S_4))`.

Figure 5.278: All solutions corresponding to the non ground example of the DERANGEMENT constraint of the All solutions slot; in the left-hand side the `index` attributes are displayed as indices of the `succ` attribute, while in the right-hand side they are directly displayed within each node.
DERANGEMENT

Typical

$|\text{NODES}| > 2$

Symmetries

- Items of NODES are permutable.
- Attributes of NODES are permutable w.r.t. permutation $(\text{index, succ})$ (permutation applied to all items).

Remark

A special case of the CYCLE [47] constraint.

Solution density for DERANGEMENT

See also

- common keyword: ALLDIFFERENT, CYCLE (permutation).
- implied by: SYMMETRIC_ALLDIFFERENT.
- implies: TWIN.
- implies (items to collection): K_ALLDIFFERENT, LEX_ALLDIFFERENT.

Keywords

- characteristic of a constraint: sort based reformulation.
- combinatorial object: permutation.
- constraint type: graph constraint.
- filtering: arc-consistency, DFS-bottleneck.
- final graph structure: one_succ.

Cond. implications

- DERANGEMENT(NODES)
  - implies PERMUTATION(VARIABLES : NODES).
Arc input(s) NODES
Arc generator $CLIQUE\mapsto collection(nodes1, nodes2)$
Arc arity 2
Arc constraint(s)
- $nodes1\cdot succ = nodes2\cdot index$
- $nodes1\cdot succ \neq nodes1\cdot index$
Graph property(ies) $NTREE = 0$
Graph class ONE_SUCCE

Graph model

Parts (A) and (B) of Figure 5.279 respectively show the initial and final graph associated with the Example slot. The DERANGEMENT constraint holds since the final graph does not contain any vertex that does not belong to a circuit (i.e., $NTREE = 0$).

Figure 5.279: Initial and final graph of the DERANGEMENT constraint

In order to express the binary constraint that links two vertices of the NODES collection one has to make explicit the index value of the vertices. This is why the DERANGEMENT constraint considers objects that have two attributes:

- One fixed attribute index that is the identifier of the vertex,
- One variable attribute succ that is the successor of the vertex.

Forbidding cycles of length one is achieved by the second condition of the arc constraint.

Signature

Since 0 is the smallest possible value of $NTREE$ we can rewrite the graph property $NTREE = 0$ to $NTREE \leq 0$. This leads to simplify $NTREE$ to $NTREE$. 
### DIFFER_FROM_AT_LEAST_K_POS

**Origin**
Inspired by [188].

**Constraint**
\[
\text{DIFFER\_FROM\_AT\_LEAST\_K\_POS}(K, \text{VECTOR1}, \text{VECTOR2})
\]

**Type**
\[
\text{VECTOR} : \text{collection}(	ext{var} - \text{dvar})
\]

**Arguments**
- \( K \) : \text{int}
- \( \text{VECTOR1} \) : \text{VECTOR}
- \( \text{VECTOR2} \) : \text{VECTOR}

**Restrictions**
- \( |\text{VECTOR}| \geq 1 \)
- \( \text{required}(\text{VECTOR}, \text{var}) \)
- \( K \geq 0 \)
- \( K \leq |\text{VECTOR1}| \)
- \( |\text{VECTOR1}| = |\text{VECTOR2}| \)

**Purpose**
Enforce two vectors \( \text{VECTOR1} \) and \( \text{VECTOR2} \) to differ from at least \( K \) positions.

**Example**
\[(2, \langle 2, 5, 2, 0 \rangle, \langle 3, 6, 2, 1 \rangle)\]

The \( \text{DIFFER\_FROM\_AT\_LEAST\_K\_POS} \) constraint holds since the first and second vectors differ from 3 positions, which is greater than or equal to \( K = 2 \).

**Typical**
- \( K > 0 \)
- \( K < |\text{VECTOR1}| \)
- \( |\text{VECTOR1}| > 1 \)

**Symmetries**
- Arguments are \textit{permutable} \text{w.r.t.} permutation \((K) \) \((\text{VECTOR1}, \text{VECTOR2})\).
- \( K \) can be \textit{decreased} to any value \( \geq 0 \).
- Items of \( \text{VECTOR1} \) and \( \text{VECTOR2} \) are \textit{permutable} \text{w.r.t.} \text{same permutation used}.

**Arg. properties**
Extensible \text{w.r.t.} \text{VARIABLES1} and \text{VARIABLES2} \text{w.r.t.} \text{add items at same position}.

**Remark**
Used in the \text{Arc constraint(s)} slot of the \text{ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS} constraint.

**Used in**
\text{ALL\_DIFFER\_FROM\_AT\_LEAST\_K\_POS}.

**See also**
- \text{implied by:} \text{DIFFER\_FROM\_EXACTLY\_K\_POS} \( (\geq K \text{ replaced by } = K) \).

**Keywords**
- \text{characteristic of a constraint:} \text{vector, automaton, automaton with counters.}
- \text{constraint network structure:} \text{alpha-acyclic constraint network(2).}
- \text{constraint type:} \text{value constraint.}
**Graph model**

Parts (A) and (B) of Figure 5.280 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

**Figure 5.280**: Initial and final graph of the **DIFFER_FROM_AT_LEAST_K_POS** constraint
Figure 5.281 depicts the automaton associated with the `DIFFER_FROM_AT_LEAST_K_POS` constraint. Let \( \text{VAR1}_i \) and \( \text{VAR2}_i \) be the \( i^{th} \) variables of the \( \text{VECTOR1} \) and \( \text{VECTOR2} \) collections. To each pair of variables \((\text{VAR1}_i, \text{VAR2}_i)\) corresponds a signature variable \( S_i \). The following signature constraint links \( \text{VAR1}_i, \text{VAR2}_i \) and \( S_i \): \( \text{VAR1}_i = \text{VAR2}_i \iff S_i \). 

\[
\begin{align*}
\text{VAR1}_i = \text{VAR2}_i & \quad \{ C \leftarrow 0 \} \\
\text{VAR1}_i \neq \text{VAR2}_i, & \quad \{ C \leftarrow C + 1 \}
\end{align*}
\]

\( C \geq K \)

Figure 5.281: Automaton of the `DIFFER_FROM_AT_LEAST_K_POS` constraint

Figure 5.282: Hypergraph of the reformulation corresponding to the automaton of the `DIFFER_FROM_AT_LEAST_K_POS` constraint
DIFFER_FROM_AT_LEAST_K_POS
5.118 DIFFER_FROM_AT_MOST_K_POS

Origin
Inspired by DIFFER_FROM_AT_LEAST_K_POS.

Constraint
DIFFER_FROM_AT_MOST_K_POS(K, VECTOR1, VECTOR2)

Type
VECTOR : collection(var−dvar)

Arguments
K : int
VECTOR1 : VECTOR
VECTOR2 : VECTOR

Restrictions
|VECTOR| ≥ 1
required(VECTOR, var)
K ≥ 0
K ≤ |VECTOR1|
|VECTOR1| = |VECTOR2|

Purpose
Enforce two vectors VECTOR1 and VECTOR2 to differ from at most K positions.

Example
(3, ⟨2, 5, 2, 0⟩, ⟨3, 6, 2, 0⟩)

The DIFFER_FROM_AT_MOST_K_POS constraint holds since the first and second vectors differ from 2 positions, which is less than or equal to K = 3.

Typical
K > 0
K < |VECTOR1|
|VECTOR1| > 1

Symmetries
- Arguments are permutable w.r.t. permutation (K) (VECTOR1, VECTOR2).
- K can be increased to any value ≤ |VECTOR1|.
- Items of VECTOR1 and VECTOR2 are permutable (same permutation used).

Arg. properties
Contractible wrt. VARIABLES1 and VARIABLES2 (remove items from same position).

Used in
ALL_DIFFER_FROM_AT_MOST_K_POS.

See also
implied by: DIFFER_FROM_EXACTLY_K_POS (≤ K replaced by = K).

</table>

The DIFFER_FROM_EXACTLY_K_POS constraint holds since the first and second vectors differ from 2 positions, which is equal to \(K = 2\).

Typical

\[
\begin{align*}
K & > 0 \\
K & \leq |\text{VECTOR1}| \\
|\text{VECTOR1}| & > 1
\end{align*}
\]

Symmetries

- Arguments are permutable w.r.t. permutation \((K, \text{VECTOR1}, \text{VECTOR2})\).
- Items of \text{VECTOR1} and \text{VECTOR2} are permutable \(\text{same permutation used}\).

Arg. properties

Functional dependency: \(K\) determined by \text{VECTOR1}.

Used in

ALL_DIFFER_FROM_EXACTLY_K_POS.

See also

- \text{implies}: DIFFER_FROM_AT_LEAST_K_POS \((= K \ replaced \ by \ \geq K)\), DIFFER_FROM_AT_MOST_K_POS \((= K \ replaced \ by \ \leq K)\).
- \text{system of constraints}: ALL_DIFFER_FROM_EXACTLY_K_POS.

Keywords

characteristic of a constraint: vector.
constraint arguments: pure functional dependency.
constraint type: value constraint.
modelling: functional dependency.
Graph model

Parts (A) and (B) of Figure 5.284 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold.

Figure 5.284: Initial and final graph of the DIFFER_FROM_EXACTLY_K_POS constraint
5.120 DIFFN

Origin [47]
Constraint DIFFN(ORTHOTOPES)
Synonyms DISJOINT, DISJOINT1, DISJOINT2, DIFF2.
Type ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)
Argument ORTHOTOPES : collection(orth − ORTHOTOPE)
Restrictions |ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori ≤ ORTHOTOPE.end
required(ORTHOTOPES, orth)
same_size(ORTHOTOPES, orth)

Purpose Generalised multi-dimensional non-overlapping constraint: Holds if, for each pair of orthotopes \( (O_1, O_2) \), \( O_1 \) and \( O_2 \) do not overlap. Two orthotopes do not overlap if one of the orthotopes has zero size or if there exists at least one dimension where their projections do not overlap.

Example

```
\begin{align*}
\text{orth} & \leftarrow \text{orth} - \langle \text{ori} - 2, \text{siz} - 2, \text{end} = -4, \text{ori} - 1, \text{siz} - 2, \text{end} = -3 \rangle, \\
\text{orth} & \leftarrow \text{orth} - \langle \text{ori} - 4, \text{siz} - 4, \text{end} = -8, \text{ori} - 2, \text{siz} - 2, \text{end} = -4 \rangle, \\
\text{orth} & \leftarrow \langle \text{ori} - 6, \text{siz} = 5, \text{end} = -11, \text{ori} - 5, \text{siz} = 2, \text{end} = -7 \rangle
\end{align*}
```

Figure 5.285 represents the position of the three rectangles of the example. The coordinates of the leftmost lowest corner of each rectangle are stressed in bold. The DIFFN constraint holds since the three rectangles do not overlap as explained in Figure 5.286.

Figure 5.285: Illustration of the Example slot: the three rectangles
$R_1$ and $R_2$ do not overlap since their projections onto dimension 1 do not intersect.

$R_1$ and $R_3$ do not overlap since their projections onto both dimensions do not intersect.

$R_2$ and $R_3$ do not overlap since their projections onto dimension 2 do not intersect.

Figure 5.286: Illustration of the Example slot: the reasons (A), (B), (C) why the pairs of rectangles $(R_1, R_2)$, $(R_1, R_3)$, $(R_2, R_3)$ do not overlap.

All solutions Figure 5.287 gives all solutions to the following non ground instance of the DIFFN constraint:

\[
\begin{align*}
X_1 &\in [1, 3], \quad EX_1 \in [1, 9], \quad Y_1 \in [1, 3], \quad EY_1 \in [1, 9], \\
X_2 &\in [1, 3], \quad EX_2 \in [1, 9], \quad Y_2 \in [2, 3], \quad EY_2 \in [1, 9], \\
X_3 &\in [1, 2], \quad EX_3 \in [1, 9], \quad Y_3 \in [1, 4], \quad EY_3 \in [1, 9], \\
X_4 &\in [1, 3], \quad EX_4 \in [1, 9], \quad Y_4 \in [1, 3], \quad EY_4 \in [1, 9], \\
\text{DIFFN} &\left( \langle X_1 \ 2 \ EX_1, \ Y_1 \ 3 \ EY_1 \rangle, \ \langle X_2 \ 3 \ EX_2, \ Y_2 \ 2 \ EY_2 \rangle, \ \langle X_3 \ 1 \ EX_3, \ Y_3 \ 4 \ EY_3 \rangle, \ \langle X_4 \ 4 \ EX_4, \ Y_4 \ 1 \ EY_4 \rangle \right). 
\end{align*}
\]

Typical

\[|\text{ORTHOTOPE}| > 1\]
\[|\text{ORTHOTOPE.siz}| > 0\]
\[|\text{ORTHOTOPES}| > 1\]

Symmetries

- Items of ORTHOTOPES are permutable.
- Items of ORTHOTOPES.orth are permutable (same permutation used).
- ORTHOTOPES.orth.siz can be decreased to any value $\geq 0$.
- One and the same constant can be added to the ori and end attributes of all items of ORTHOTOPES.orth.

Arg. properties

Contractible wrt. ORTHOTOPES.

Usage

The DIFFN constraint occurs in placement and scheduling problems. It was used, for example, for scheduling problems where one has to both assign each non-preemptive task to a resource and fix its origin so that two tasks, which are assigned to the same resource, do not overlap. When the resource is a set of persons to which non-preemptive tasks have to be assigned this corresponds to so called timetabling problems. A second practical application from the area of the design of memory-dominated embedded systems [413] can be found in [414]. Together with arithmetic and CUMULATIVE constraints, the DIFFN constraint was used in [412] for packing more complex shapes such as angles. Figure 5.288 illustrates the angle packing problem on an instance involving 10 angles taken from [412].

One other packing problem attributed to S. Golomb is to find the smallest square that can contain the set of consecutive squares from $1 \times 1$ up to $n \times n$ so that these squares do not overlap each other (see the smallest rectangle area problem).
Remark

Unlike the definition of the Purpose slot the original paper [47] introducing the DIFFN constraint imposes all orthotopes sizes to be different from 0. But it is convenient to allow variable sizes which can be assigned value 0 to model the fact that an orthotope can be skipped.

When we have segments (respectively rectangles) the DIFFN constraint is referenced under the name DISJOINT1 (respectively DISJOINT2) in SICStus Prolog [108]. When we have rectangles the DIFFN constraint is also called DIFF2 in JaCoP. In MiniZinc (http://www.minizinc.org/) the DIFFN constraint considers only rectangles.

It was shown in [417, page 137] that, finding out whether a non-overlapping constraint between a set of rectangles has a solution or not is NP-hard. This was achieved by reduction from sequencing with release times and deadlines.

In the two-dimensional case, when rectangles heights are all equal to one and when rectangles starts in the first dimension are all fixed, the DIFFN constraint can be rewritten as a K,ALLDIFFERENT constraint corresponding to a system of ALLDIFFERENT constraints derived from the maximum cliques of the corresponding interval graph.
Algorithm

Checking whether a DIFFN constraint for which all variables are fixed is satisfied or not is related to the Klee’s measure problem: given a collection of axis-aligned multi-dimensional boxes, how quickly can one compute the volume of their union. Then the DIFFN constraint holds if the volume of the union is equal to the sum of the volumes of the different boxes.

A first possible method for filtering non zero size orthotopes is to use constructive disjunction. The idea is to try out each alternative of a disjunction (e.g., given two orthotopes $o_1$ and $o_2$ that should not overlap, we successively assume for each dimension that $o_1$ finishes before $o_2$, and that $o_2$ finishes before $o_1$) and to remove values that were pruned in all alternatives. For the two-dimensional case of DIFFN a second possible solution used in [372] is to represent explicitly the two-dimensional domain of the origin of each rectangle by a quadtree [378] and to accumulate all forbidden regions within this data structure. As for conventional domain variables, a failure occurs when a two-dimensional domain get empty.

A third possible filtering algorithm based on sweep is described in [34].

The thesis of J. Nelissen [303] considers the case where all rectangles have the same size and can be rotated from 90 degrees (i.e., the pallet loading problem.). For the $n$-dimensional case of DIFFN a filtering algorithm handling the fact that two objects do not overlap is given in [50].

Extensions of the non-overlapping constraint to polygons and to more complex shapes are respectively described in [50] and in [367]. Specialised propagation algorithms for the squared squares problem [94] (based on the fact that no waste is permitted) are given in [192] and in [191].

The CUMULATIVE constraint can be used as a necessary condition for the DIFFN constraint. Figure 5.290 illustrates this point for the two-dimensional case. A first (respectively second) CUMULATIVE constraint is obtained by forgetting the $y$-coordinate (respectively the $x$-coordinate) of the origin of each rectangle occurring in a DIFFN constraint. Parts (B) and (C) respectively depict the cumulated profiles associated with the projection of the rectangles depicted by part (A) on the $x$ and $y$ axes.

The CUMULATIVE constraint is a necessary but not sufficient condition for the two-dimensional case of the DIFFN constraint. Figure 5.291 illustrates this point on an
Figure 5.289: A hard instance from [303, page 165]: A solution for packing 99 rectangles of size $5 \times 9$ into a rectangle of size $86 \times 52$

example taken from [84] where one has to place the 8 rectangles $R_1, R_2, R_3, R_4, R_5, R_6, R_7, R_8$ of respective size $5 \times 2, 8 \times 2, 6 \times 1, 5 \times 1, 2 \times 1, 3 \times 1, 2 \times 2$ and $1 \times 2$ in a big rectangle of size $12 \times 4$. As shown by Figure 5.291 there is a cumulative solution where $R_8$ is split in two parts but M. Hujter proves in [232] that there is no solution where no rectangle is split.

In the context of $n$ parallelepipeds that have to be packed [198, 272] within a box of sizes $X \times Y \times Z$ one can proceed as follows for stating three CUMULATIVE constraints. The $i^{th}$ (with $i \in [1, n]$) parallelepiped is described by the following attributes:

- $ox_i, oy_i, oz_i$ (with $i \in [1, n]$) the coordinates of its origin on the $x$, $y$ and $z$-axes.
- $sx_i, sy_i, sz_i$ (with $i \in [1, n]$) its sizes on the $x$, $y$ and $z$-axes.
- $px_i, py_i, pz_i$ (with $i \in [1, n]$) the surfaces of its projections onto the planes $yz$, $xz$, and $xy$ respectively equal to $sy�sz_i$, $sx�sz_i$, and $sx�sy_i$.
- $v_i$ its volume (equal to $sx�sy�sz_i$).

For the placement of $n$ parallelepipeds we get the following necessary conditions that respectively correspond to three CUMULATIVE constraints on the planes $yz$, $xz$, and $xy$:

\[
\begin{align*}
\forall i \in [1, X] : & \sum_{j \mid oy_j \leq i \leq oy_j + sy_j - 1} px_j \leq YZ \\
\forall i \in [1, Y] : & \sum_{j \mid ox_j \leq i \leq ox_j + sx_j - 1} py_j \leq XZ \\
\forall i \in [1, Z] : & \sum_{j \mid oz_j \leq i \leq oz_j + sz_j - 1} pz_j \leq XY
\end{align*}
\]

Reformulation

Based on the fact that two orthotopes do not overlap if there exists at least one dimension where their projections do not overlap one can reformulate the DIFFN(ORTHOTOPES) constraint as a disjunction of inequalities between the origin and the end attributes. In addition one has to link the origin, the size and the end attributes of each orthotope in each dimension.

If we consider the example described in the Example slot we get the following reformulation:
Figure 5.290: Looking from the perspective of the CUMULATIVE constraint in a two-dimensional rectangles placement problem: projecting the three rectangles of (A) on the $x$ axis (B) and on the $y$ axis (C)

Figure 5.291: Illustrating the necessary but not sufficient placement condition: the rectangle $R_8$ is split in two parts

- $4 = 2 + 2$ (link between the origin, size and end in dimension 1 of the first orthotope),
- $4 = 1 + 3$ (link between the origin, size and end in dimension 2 of the first orthotope),
- $8 = 4 + 4$ (link between the origin, size and end in dimension 1 of the second...
orthotope),

- $6 = 3 + 3$ (link between the origin, size and end in dimension 2 of the second orthotope),

- $11 = 9 + 2$ (link between the origin, size and end in dimension 1 of the third orthotope),

- $7 = 4 + 3$ (link between the origin, size and end in dimension 2 of the third orthotope),

- $4 \leq 4 \lor 8 \leq 2 \lor 4 \leq 3 \land 6 \leq 1$ (non-overlapping between the first and second orthotopes),

- $4 \leq 9 \lor 11 \leq 2 \lor 4 \leq 4 \lor 7 \leq 1$ (non-overlapping between the first and third orthotopes),

- $8 \leq 9 \lor 11 \leq 4 \lor 6 \leq 4 \lor 7 \leq 3$ (non-overlapping between the second and third orthotopes).

heuristics: heuristics for two-dimensional rectangle placement problems.

modelling: disjunction, assignment dimension, assignment to the same set of values, assigning and scheduling tasks that run in parallel, relaxation dimension, sequence dependent set-up, multi-site employee scheduling with calendar constraints, scheduling with machine choice, calendars and preemption.

modelling exercises: assignment to the same set of values, assigning and scheduling tasks that run in parallel, relaxation dimension, sequence dependent set-up, multi-site employee scheduling with calendar constraints, scheduling with machine choice, calendars and preemption.

problems: strip packing, two-dimensional orthogonal packing, pallet loading.

puzzles: squared squares, packing almost squares, Partridge, pentomino, Shikaku, smallest square for packing consecutive dominoes, smallest square for packing rectangles with distinct sizes, smallest rectangle area, Conway packing problem.
The DIFFN constraint is expressed by using two graph constraints:

- The first graph constraint forces for each dimension and for each orthotope the link between the corresponding ori, siz and end attributes.
- The second graph constraint imposes each pair of distinct orthotopes to not overlap.

Parts (A) and (B) of Figure 5.292 respectively show the initial and final graph associated with the second graph constraint of the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold.

Figure 5.292: Initial and final graph of the DIFFN constraint

**Signature**

Since \( |\text{ORTHOTOPES}| \) is the maximum number of vertices of the final graph of the first graph constraint we can rewrite \( \text{NARC} = |\text{ORTHOTOPES}| \) to \( \text{NARC} \geq |\text{ORTHOTOPES}| \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).
Since we use the $\text{CLIQUE}(\neq)$ arc generator on the $\text{ORTHOTOPES}$ collection, $|\text{ORTHOTOPES}| \cdot |\text{ORTHOTOPES}| - |\text{ORTHOTOPES}|$ is the maximum number of vertices of the final graph of the second graph constraint. Therefore we can rewrite $\text{NARC} = |\text{ORTHOTOPES}| \cdot |\text{ORTHOTOPES}| - |\text{ORTHOTOPES}|$ to $\text{NARC} \geq |\text{ORTHOTOPES}| \cdot |\text{ORTHOTOPES}|$. Again, this leads to simplify $\text{NARC}$ to $\text{NARC}$.

---

**Quiz**

**EXERCISE 1 (checking whether a ground instance holds or not)**

A. Does the constraint $\text{DIFFN}((1 1 1, 2 4), (5 1 6, 4 1 5))$ hold?

B. Does the constraint $\text{DIFFN}((2 4 3 2 5), (4 3 7, 4 2 6), (8 2 10, 2 3 5))$ hold?

C. Does the constraint $\text{DIFFN}((2 4 2 4 4), (4 5 9, 4 2 6), (8 2 10, 2 3 5))$ hold?

D. Does the constraint $\text{DIFFN}((3 2 5), (4 0 4), (6 3 9))$ hold?

*Hint: go back to the definition of $\text{DIFFN}$.

**EXERCISE 2 (finding all solutions)**

Give all the solutions to the constraint:

$$
\begin{align*}
\{ OX_1 \in [1, 5], & \quad EX_1 \in [1, 5], \quad OY_1 \in [1, 5], \quad EY_1 \in [1, 5], \\
OX_2 \in [1, 5], & \quad EX_2 \in [1, 5], \quad OY_2 \in [1, 5], \quad EY_2 \in [1, 5], \\
OX_3 \in [1, 5], & \quad EX_3 \in [1, 5], \quad OY_3 \in [1, 5], \quad EY_3 \in [1, 5], \\
\text{DIFFN} & \left( \begin{array}{c}
OX_1 1 \quad EX_1 \\
OX_2 4 \quad EX_2 \\
OX_3 3 \quad EX_3 \\
OY_1 3 \quad EY_1 \\
OY_2 1 \quad EY_2 \\
OY_3 3 \quad EY_3
\end{array} \right) \right).
\end{align*}
$$

*Hint: consider rectangles by decreasing surface and focus on the coordinates of their origins $(OX_3, OY_3)$, $(OX_2, OY_2)$ and $(OX_1, OY_1)$; enumerate solutions in lexicographic order of $(OX_3, OY_3)$. 
EXERCISE 3 (finding the unique solution)*

Find the unique solution to the constraint:

\[
\begin{cases}
OX_1 \in [1, 8], & EX_1 \in [1, 8], & OY_1 \in [1, 8], & EY_1 \in [1, 8], \\
OX_2 \in [1, 8], & EX_2 \in [1, 8], & OY_2 \in [1, 8], & EY_2 \in [1, 8], \\
OX_3 \in [1, 8], & EX_3 \in [1, 8], & OY_3 \in [1, 8], & EY_3 \in [1, 8], \\
OX_4 \in [1, 8], & EX_4 \in [1, 8], & OY_4 \in [1, 8], & EY_4 \in [1, 8], \\
OX_5 \in [1, 8], & EX_5 \in [1, 8], & OY_5 \in [1, 8], & EY_5 \in [1, 8],
\end{cases}
\]

\[
\text{DIFFN} \left( \begin{pmatrix} (OX_1 \ 2 \ EX_1, & OY_1 \ 5 \ EY_1) \\ (OX_2 \ 5 \ EX_2, & OY_2 \ 1 \ EY_2) \\ (OX_3 \ 2 \ EX_3, & OY_3 \ 4 \ EY_3) \\ (OX_4 \ 4 \ EX_4, & OY_4 \ 2 \ EY_4) \\ (OX_5 \ 3 \ EX_5, & OY_5 \ 3 \ EY_5) \\ (1 \ 3 \ 4, & 1 \ 3 \ 4) \end{pmatrix} \right).
\]

*Hint: reason on whose compulsory parts of the projections of the rectangles onto the x and y axes.

EXERCISE 4 (degrees of violation for non-overlapping)*

A. Give the variable-based degree of violation* of the constraint

\[
\text{DIFFN} \left( \begin{pmatrix} (3 \ 2 \ 5, & 4 \ 2 \ 6) \\ (4 \ 5 \ 9, & 5 \ 2 \ 7) \\ (6 \ 2 \ 8, & 3 \ 5 \ 8) \\ (7 \ 1 \ 8, & 2 \ 4 \ 6) \end{pmatrix} \right).
\]

B. Give the decomposition-based degree of violation* of the same constraint.

C. In the decomposition-based degree of violation each violated binary constraint contributes +1 to the degree of violation, which does not consider how much two orthotopes overlap. For the same constraint give the overlap decomposition-based degree of violation where the degree of violation of a binary no-overlap constraint is equal to the overlap between the corresponding orthotopes.

D. Given two fixed orthotopes of the DIFFN constraint, propose a formula for computing how much these orthotopes overlap.

*Hint: focus on the rectangles that overlap; by changing one coordinate of a rectangle one can move it (A); count how many rectangles overlap (B); count how much each pair of rectangles overlaps (C).

*Given a constraint for which all variables are fixed, the variable-based degree of violation is the minimum number of variables to assign differently in order to satisfy the constraint.

*Given a constraint that can be decomposed in a conjunction of binary constraints, the decomposition-based degree of violation is the number of binary constraints that do not hold.
EXERCISE 5 (nasty pattern)\(^a\)

Find a solution to the following constraint, or prove that no solution exists:

\[
\begin{cases}
OX_1 \in [0, 2], & EX_1 \in [0, 9], & OY_1 \in [0, 2], & EY_1 \in [0, 9], \\
OX_2 \in [1, 3], & EX_2 \in [0, 9], & OY_2 \in [1, 3], & EY_2 \in [0, 9], \\
OX_3 \in [3, 4], & EX_3 \in [0, 9], & OY_3 \in [3, 4], & EY_3 \in [0, 9], \\
OX_4 \in [3, 5], & EX_4 \in [0, 9], & OY_4 \in [3, 5], & EY_4 \in [0, 9], \\
OX_5 \in [4, 6], & EX_5 \in [0, 9], & OY_5 \in [4, 6], & EY_5 \in [0, 9], \\
\end{cases}
\]

\(^a\)Hint: focus on the compulsory part of the squares.
SOLUTION TO EXERCISE 1

A. No, since the first rectangle 
(1 1 1, 2 2 4) is not well formed, 
i.e., 1 + 1 ≠ 1.

B. Yes, since the three rectangles do 
not overlap:

- Rectangles 1 and 2 do not overlap since their 
  projections onto the x axis 
  do not overlap,
- Rectangles 2 and 3 do not overlap since their 
  projections onto the x axis 
  do not overlap,
- Rectangles 1 and 3 do not overlap since their 
  projections onto the x axis 
  do not overlap.

C. No, since rectangles 2 and 3 
overlap, i.e., their projections onto 
the x and y axes both overlap.

D. Yes, since line segments 1 and 3 
do not overlap and since the size 
of line segment 2 is zero.
SOLUTION TO EXERCISE 2

the four solutions (once \( R_3 \) is fixed, \( R_2 \) and \( R_1 \) are also fixed)

\[
\begin{align*}
&\begin{cases}
\langle\langle 4 1 5, 1 3 4 \rangle, \langle 1 4 5, 4 1 5 \rangle, \langle 1 3 4, 1 3 4 \rangle \rangle \\
\langle\langle 1 1 2, 2 3 5 \rangle, \langle 1 4 5, 1 1 2 \rangle, \langle 2 3 5, 2 3 5 \rangle \rangle \\
\langle\langle 1 1 2, 1 3 4 \rangle, \langle 1 4 5, 4 1 5 \rangle, \langle 2 3 5, 1 3 4 \rangle \rangle \\
\langle\langle 4 1 5, 2 3 5 \rangle, \langle 1 4 5, 1 1 2 \rangle, \langle 2 3 5, 1 3 4 \rangle \rangle \\
\langle\langle 4 1 5, 2 3 5 \rangle, \langle 1 4 5, 1 1 2 \rangle, \langle 2 3 5, 2 3 5 \rangle \rangle \\
\end{cases}
\end{align*}
\]
SOLUTION TO EXERCISE 3

We go through the following reasoning steps:

A. **[SELECTING THE \( x \) OR \( y \) AXIS FOR REASONING]**
   Among the rectangles that have the largest side lengths, i.e., \( R_1 : 2 \times 5 \) and \( R_2 : 5 \times 1 \), we select the rectangle that has the largest surface, i.e., \( R_1 \). Since the largest size of \( R_1 \) is located in dimension \( y \) we first choose to reason on the compulsory parts of the projections of the rectangles onto the \( y \) axis.

B. **[REASONING ON THE PROJECTIONS ONTO THE \( y \) AXIS]**
   We focus on the projections of the rectangles onto the \( y \) axis and gradually build the cumulated profile of their compulsory parts. Fixed (respectively not completely fixed) projections use a saturated (respectively unsaturated) colour. The gray square corresponds to an initially fixed square.

C. **[FILTERING A RECTANGLE WRT ONE OTHER RECTANGLE]**
   A no-overlap constraint between two rectangles can be represented as a disjunction with four alternatives:
   - on the \( x \) axis the first rectangle ends before the start of the second rectangle,
   - on the \( x \) axis the second rectangle ends before the start of the first rectangle,
   - on the \( y \) axis the first rectangle ends before the start of the second rectangle,
   - on the \( y \) axis the second rectangle ends before the start of the first rectangle.

   If we consider the fixed \( 3 \times 3 \) gray square and the rectangle \( R_4 \) we have \( 4 \leq OX_4 \lor EX_4 \leq 1 \). \( V_4 \leq 1 \). The part \( 4 \leq 1 \) does not hold. Since the minimum value of \( EX_4 \) is equal to 5 the inequality \( EX_4 \leq 1 \) does also not hold. Consequently \( 4 \leq OX_4 \) must hold and the minimum value of \( OX_4 \) is equal to 4. Moreover since the maximum value of \( OX_4 \) is 4 we have \( OX_4 = 4 \).
SOLUTION TO EXERCISE 3 (continued)

D. [REASONING ON THE PROJECTIONS ONTO THE x AXIS]
We focus on the projections of the rectangles onto the x axis and gradually build the cumulated profile of their compulsory parts. Fixed (respectively not completely fixed) projections use a saturated (respectively unsaturated) colour.

E. [PUTTING THINGS TOGETHER]
For any pair of distinct rectangles $i, j$ we check
$EX_i \leq OX_j \lor EX_j \leq OX_i \lor EY_i \leq OY_j \lor EY_j \leq OY_i$, i.e., there exists at least one dimension where the projections of the two rectangles do not overlap. We obtain the following unique solution.
SOLUTION TO EXERCISE 4

A. Since point \((7, 5)\) is included in the three rectangles \(②, ③, ④\) (see Figure (A1)), we need to modify the attributes of at least two rectangles. Figure (A2) shows a solution where only rectangles ② and ④ are translated. Therefore the variable-based degree of violation is equal to 2.

B. Figure (B) shows the constraint network associated with the decomposition where each vertex corresponds to a rectangle and each edge to a binary no-overlap constraint between two rectangles. Edges where the corresponding binary constraint holds (respectively does not hold) are coloured in blue (in red). Consequently the decomposition-based degree of violation is equal to 4 (i.e., each pair \((①, ②), (②, ③), (③, ④)\) corresponds to two overlapping rectangles).
SOLUTION TO EXERCISE 4 (continued)

C. As illustrated by Figure (C), the overlap decomposition-based degree of violation is equal to 9 since:

- the overlap between rectangles ① and ② is equal to 1,
- the overlap between rectangles ② and ③ is equal to 4,
- the overlap between rectangles ② and ④ is equal to 1,
- the overlap between rectangles ③ and ④ is equal to 3,
- the other pairs of rectangles do not overlap.

D. Given two orthotopes i and j, defined by their ends and their origins in each dimension, their overlap is defined by

$$\prod_{d=1}^{[\text{ORTHOTOPE}]} \max(0, \min(\text{end}_{i,d}, \text{end}_{j,d}) - \max(\text{ori}_{i,d}, \text{ori}_{j,d}))$$.
5.121  DIFFN_COLUMN

**Origin**
CHIP: option guillotine cut (column) of DIFFN.

**Constraint**
DIFFN_COLUMN(ORTHOTOPES, DIM)

**Type**
ORTHOTOPE : collection(ori−dvar, siz−dvar, end−dvar)

**Arguments**
ORTHOTOPES : collection(orth − ORTHOTOPE)
DIM : int

**Restrictions**
|ORTHOTOPE| > 0
require_at_least(2, ORTHOTOPE, [ori, siz, end])
ORTHOTOPE.siz ≥ 0
ORTHOTOPE.ori ≤ ORTHOTOPE.end
required(ORTHOTOPE, orth)
same_size(ORTHOTOPE, orth)
DIM > 0
DIM ≤ |ORTHOTOPE|
DIFFN(ORTHOTOPES)

**Purpose**
Extension of the generalised multi-dimensional non-overlapping diffn constraint. Holds if, for each pair of orthotopes \(O_1, O_2\) the following conditions hold:
- \(O_1\) and \(O_2\) do not overlap. Two orthotopes do not overlap if one of the orthotopes has zero size or if there exists at least one dimension where their projections do not overlap.
- Let \(P_1\) and \(P_2\) respectively denote the projections of \(O_1\) and \(O_2\) onto dimension DIM. If \(P_1\) and \(P_2\) overlap then the size of their intersection is equal to the size of \(O_1\) in dimension DIM, as well as to the size of \(O_2\) in dimension DIM.

**Example**

\[
\begin{align*}
\text{orth} & - \langle \text{ori} - 1 \text{ siz} - 3 \text{ end} - 4, \text{ori} - 3 \text{ siz} - 2 \text{ end} - 5 \rangle, \\
\text{orth} & - \langle \text{ori} - 9 \text{ siz} - 1 \text{ end} - 10, \text{ori} - 4 \text{ siz} - 3 \text{ end} - 7 \rangle, \\
\text{orth} & - \langle \text{ori} - 4 \text{ siz} - 2 \text{ end} - 6, \text{ori} - 3 \text{ siz} - 4 \text{ end} - 7 \rangle, \\
\text{orth} & - \langle \text{ori} - 1 \text{ siz} - 3 \text{ end} - 4, \text{ori} - 6 \text{ siz} - 1 \text{ end} - 7 \rangle, \\
\text{orth} & - \langle \text{ori} - 6 \text{ siz} - 2 \text{ end} - 8, \text{ori} - 1 \text{ siz} - 4 \text{ end} - 5 \rangle, \\
\text{orth} & - \langle \text{ori} - 10 \text{ siz} - 1 \text{ end} - 11, \text{ori} - 1 \text{ siz} - 1 \text{ end} - 2 \rangle, \\
\text{orth} & - \langle \text{ori} - 9 \text{ siz} - 1 \text{ end} - 10, \text{ori} - 1 \text{ siz} - 1 \text{ end} - 2 \rangle, \\
\text{orth} & - \langle \text{ori} - 6 \text{ siz} - 2 \text{ end} - 8, \text{ori} - 6 \text{ siz} - 1 \text{ end} - 7 \rangle,
\end{align*}
\]

Figure 5.293 represents the respective position of the eight rectangles of the example. The coordinates of the leftmost lowest corner of each rectangle are stressed in
The **DIFFN_COLUMN** constraint holds since (1) the eight rectangles do not overlap and since (2) when their projection onto dimension $\text{DIM} = 1$ overlap the size of their intersection is equal to the size of the corresponding rectangles in dimension $\text{DIM} = 1$.

![Illustration of the Example slot: eight non-overlapping rectangles such that, for each pair of rectangles $R_i, R_j$ ($1 \leq i < j \leq 8$), if the projections onto dimension 1 of rectangles $R_i$ and $R_j$ intersect then the size of their intersection is equal to the size of $R_i$ in dimension 1 and to the size of $R_j$ in dimension 1 (i.e. complete vertical strips along the border of any rectangle can be cut without crossing any rectangle).](image)

**Typical**

| ORTHOTOPE $|$ $>$ 1  
| ORTHOTOPE.siz $>$ 0  
| ORTHOTOPE $|$ $>$ 1  

**Symmetries**

required(ORTHOTOPES.orth)
same_size(ORTHOTOPES, orth)
DIM > 0
DIM ≤ |ORTHOTOPE|
DIFFN(ORTHOTOPES)

Purpose
Extension of the generalised multi-dimensional non-overlapping diffn constraint. Holds if, for each pair of orthotopes \((O_1, O_2)\) the following conditions hold:

- \(O_1\) and \(O_2\) do not overlap. Two orthotopes do not overlap if one of the orthotopes has zero size or if there exists at least one dimension where their projections do not overlap.

- Let \(P_1\) and \(P_2\) respectively denote the projections of \(O_1\) and \(O_2\) onto dimension \(DIM\). If \(P_1\) and \(P_2\) overlap then, either \(P_1\) is included in \(P_2\), either \(P_2\) is included in \(P_1\).
Figure 5.295 represents the respective position of the twelve rectangles of the example. The coordinates of the leftmost lowest corner of each rectangle are stressed in bold. The DIFFN INCLUDE constraint holds since (1) the twelve rectangles do not overlap and since (2) when their projection onto dimension \( DIM = 1 \) overlap one of the projections is included within the other one.

**Typical**

*| ORTHOTOPE \( \geq \) 1
ORTHOTOPE.siz \( \geq \) 0

constraint type: decomposition.
geometry: geometrical constraint, positioning constraint, orthotope.
Figure 5.295: Illustration of the Example slot: twelve non-overlapping rectangles such that, for each pair of rectangles $R_i, R_j$ ($1 \leq i < j \leq 12$), if the projections onto dimension 1 of rectangles $R_i$ and $R_j$ intersect then one of the projections is included within the other projection.
Arc input(s) | ORTHOTOPES
---|---
Arc generator | $CLIQUE(<) \mapsto collection(orthotopes1, orthotopes2)$
Arc arity | 2
Arc constraint(s) | $TWO$ _ORTH INCLUDE_ $(orthotopes1.orth, orthotopes2.orth, DIM)$
Graph property(ies) | $NARC = |ORTHOTOPES| * (|ORTHOTOPES| - 1)/2$

**Graph model**

Since showing all items produces too big graphs, parts (A) and (B) of Figure 5.296 respectively show the initial and final graph associated with the first three items of the **Example** slot. Since we use the **NARC** graph property, the arcs of the final graph are stressed in bold.

![Figure 5.296](image)

**Figure 5.296:** Initial and final graph of the DIFFN INCLUDE constraint
5.123 DISCREPANCY

Origin [181] and [434]

Constraint DISCREPANCY(VARIABLES, K)

Arguments

- VARIABLES : collection(var-dvar, bad-sint)
- K : int

Restrictions

- required(VARIABLES, var)
- required(VARIABLES, bad)
- \( K \geq 0 \)
- \( K \leq |VARIABLES| \)

Purpose

\( K \) is the number of variables of the collection VARIABLES that take their values in their respective sets of bad values.

Example

\[
\begin{pmatrix}
\text{var} \rightarrow 4 & \text{bad} \rightarrow \{1, 4, 6\}, \\
\text{var} \rightarrow 5 & \text{bad} \rightarrow \{0, 1\}, \\
\text{var} \rightarrow 5 & \text{bad} \rightarrow \{1, 6, 9\}, \\
\text{var} \rightarrow 4 & \text{bad} \rightarrow \{1, 4\}, \\
\text{var} \rightarrow 1 & \text{bad} \rightarrow \emptyset
\end{pmatrix}, 2
\]

The DISCREPANCY constraint holds since exactly \( K = 2 \) variables (i.e., the first and fourth variables) of the VARIABLES collection take their values within their respective sets of bad values.

Typical

- \( |VARIABLES| > 1 \)
- \( K < |VARIABLES| \)

Symmetries

- Items of VARIABLES are permutable.
- All occurrences of two distinct values in VARIABLES.var or VARIABLES.bad can be swapped; all occurrences of a value in VARIABLES.var or VARIABLES.bad can be renamed to any unused value.

Arg. properties

- Functional dependency: \( K \) determined by VARIABLES.
- Aggregate: VARIABLES(union), K(+).

Remark Limited discrepancy search was first introduced by M. L. Ginsberg and W. D. Harvey as a search technique in [204]. Later on, discrepancy based filtering was presented in the PhD thesis of F. Focacci [181, pages 171–172]. Finally the DISCREPANCY constraint was explicitly defined in the PhD thesis of W.-J. van Hoeve [434, page 104].
See also

- **common keyword**: AMONG (counting constraint).
- **used in graph description**: IN_SET.

Keywords

- **constraint arguments**: pure functional dependency.
- **constraint type**: value constraint, counting constraint.
- **filtering**: arc-consistency.
- **heuristics**: heuristics, limited discrepancy search.
- **modelling**: functional dependency.
Arc input(s) | VARIABLES
---------------|------------------
Arc generator  | SELF \rightarrow \text{collection}(\text{variables})
Arc arity      | 1
Arc constraint(s) | \text{IN\_SET}(\text{variables}.\text{var}, \text{variables}.\text{bad})
Graph property(ies) | \text{NARC} = K

Graph model

The arc constraint corresponds to the constraint \text{in\_set}(\text{variables}\.\text{var}, \text{variables}\.\text{bad}) defined in this catalogue. We employ the \textit{SELF} arc generator in order to produce an initial graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.297 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the \textbf{NARC} graph property, the loops of the final graph are stressed in bold.

![Figure 5.297: Initial and final graph of the DISCREPANCY constraint](image-url)
5.124 DISJ

Origin [298]

Constraint DISJ(TASKS)

Argument TASKS : collection

task–dvar,
duration–dvar,
before–svar,
position–dvar

Restrictions required(TASKS, [start, duration, before, position])
TASKS.duration ≥ 1
TASKS.position ≥ 0
TASKS.position < |TASKS|

Purpose All the tasks of the collection TASKS should not overlap. For a given task t the attributes before and position respectively correspond to the set of tasks starting before task t (assuming that the first task is labelled by 1) and to the position of task t (assuming that the first task has position 0).

Example

\[
\begin{pmatrix}
\text{start} - 1 & \text{duration} - 3 & \text{before} - \emptyset & p - 0, \\
\text{start} - 9 & \text{duration} - 1 & \text{before} - \{1, 3, 4\} & p - 3, \\
\text{start} - 7 & \text{duration} - 2 & \text{before} - \{1, 4\} & p - 2, \\
\text{start} - 4 & \text{duration} - 1 & \text{before} - \{1\} & p - 1
\end{pmatrix}
\]

(p for position)

Figure 5.298 shows the tasks of the example. Since these tasks do not overlap the DISJ constraint holds.

Typical |TASKS| > 1
Symmetries

- One and the same constant can be added to the start attribute of all items of TASKS.
- TASKS.duration can be decreased to any value $\geq 1$.

Usage

The DISJ constraint was originally applied [298] to solve the open-shop problem.

Remark

This constraint is similar to the DISJUNCTIVE constraint. In addition to the start and the duration attributes of a task $t$, the DISJ constraint introduces a set variable before that represents the set of tasks that end before the start of task $t$ as well as a domain variable position that gives the absolute order of task $t$ in the resource. Since it assumes that the first task has position 0 we have that, for a given task $t$, the number of elements of its before attribute is equal to the value of its position attribute.

Algorithm

The main idea of the algorithm is to apply in a systematic way shaving on the position attribute of a task. It is implemented in Gecode [385].

See also

common keyword: DISJUNCTIVE (scheduling constraint).
used in graph description: IN_SET.

Keywords

complexity: sequencing with release times and deadlines.
constraint arguments: constraint involving set variables.
constraint type: scheduling constraint, resource constraint, decomposition.
Arc input(s) | TASKS
--- | ---
Arc generator | $CLIQUE(\neq) \mapsto collection(tasks1, tasks2)$
Arc arity | 2
Arc constraint(s)
- $\bigvee \left(\begin{array}{l}
tasks1.\text{start} + tasks1.\text{duration} \leq tasks2.\text{start}, \\
tasks2.\text{start} + tasks2.\text{duration} \leq tasks1.\text{start}
\end{array}\right)$
- tasks1.\text{start} + tasks1.\text{duration} \leq tasks2.\text{start} \Leftrightarrow \text{IN}\_\text{SET}(tasks1.\text{key}, tasks2.\text{before})$
- tasks1.\text{start} + tasks1.\text{duration} \leq tasks2.\text{start} \Leftrightarrow tasks1.\text{position} < tasks2.\text{position}$
Graph property(ies) | $\text{NARC} = |\text{TASKS}| \ast |\text{TASKS}| - |\text{TASKS}|$

Graph model

We generate a clique with a non-overlapping constraint between each pair of distinct tasks and state that the number of arcs of the final graph should be equal to the number of arcs of the initial graph. For two tasks $t_1$ and $t_2$, the three conditions of the arc constraint respectively correspond to:

- The fact that $t_1$ ends before the start of $t_2$ or that $t_2$ ends before the start of $t_1$.
- The equivalence between the fact that $t_1$ ends before the start of $t_2$ and the fact that the identifier of task $t_1$ belongs to the before attribute of task $t_2$.
- The equivalence between the fact that $t_1$ ends before the start of $t_2$ and the fact that the position attribute of task $t_1$ is strictly less than the position attribute of task $t_2$.

Parts (A) and (B) of Figure 5.299 respectively show the initial and final graph associated with the Example slot. The DISJ constraint holds since all the arcs of the initial graph belong to the final graph: all the non-overlapping constraints holds.

Figure 5.299: Initial and final graph of the DISJ constraint
5.125 DISJOINT

**Description**
Derived from ALLDIFFERENT.

**Constraint**
\[
\text{DISJOINT}(\text{VARIABLES1}, \text{VARIABLES2})
\]

**Arguments**
- \(\text{VARIABLES1} : \text{collection(var-dvar)}\)
- \(\text{VARIABLES2} : \text{collection(var-dvar)}\)

**Restrictions**
- \(\text{required} (\text{VARIABLES1}, \text{var})\)
- \(\text{required} (\text{VARIABLES2}, \text{var})\)

**Purpose**
Each variable of the collection \(\text{VARIABLES1}\) should take a value that is distinct from all the values assigned to the variables of the collection \(\text{VARIABLES2}\).

**Example**
\[
\left(\langle 1, 9, 1, 5 \rangle, \langle 2, 7, 7, 0, 6, 8 \rangle\right)
\]
In this example, values 1, 5, 9 are used by the variables of \(\text{VARIABLES1}\) and values 0, 2, 6, 7, 8 by the variables of \(\text{VARIABLES2}\). Since there is no intersection between the two previous sets of values the DISJOINT constraint holds.

**All solutions**
Figure 5.300 gives all solutions to the following non ground instance of the DISJOINT constraint: \(\text{U}_1 \in [0, 2], \text{U}_2 \in [1, 2], \text{U}_3 \in [1, 2], \text{V}_1 \in [0, 1], \text{V}_2 \in [1, 2], \text{DISJOINT}((\text{U}_1, \text{U}_2, \text{U}_3), (\text{V}_1, \text{V}_2))\).

1. \(\langle (0, 2, 2), (1, 1) \rangle\)
2. \(\langle (1, 1, 1), (0, 2) \rangle\)
3. \(\langle (2, 2, 2), (0, 1) \rangle\)
4. \(\langle (2, 2, 2), (1, 1) \rangle\)

Figure 5.300: All solutions corresponding to the non ground example of the DISJOINT constraint of the **All solutions** slot

**Typical**
- \(|\text{VARIABLES1}| > 1\)
- \(|\text{VARIABLES2}| > 1\)
Symmetries

• Arguments are permutable w.r.t. permutation (VARIABLES1, VARIABLES2).
• Items of VARIABLES1 are permutable.
• Items of VARIABLES2 are permutable.
• An occurrence of a value of VARIABLES1.var can be replaced by any value of VARIABLES1.var.
• An occurrence of a value of VARIABLES2.var can be replaced by any value of VARIABLES2.var.
• All occurrences of two distinct values in VARIABLES1.var or VARIABLES2.var can be swapped; all occurrences of a value in VARIABLES1.var or VARIABLES2.var can be renamed to any unused value.

Arg. properties

• Contractible wrt. VARIABLES1.
• Contractible wrt. VARIABLES2.

Remark

Despite the fact that this is not an uncommon constraint, it can not be modelled in a compact way neither with a disequality constraint (i.e., two given variables have to take distinct values) nor with the ALLDIFFERENT constraint. The DISJOINT constraint can bee seen as a special case of the COMMON(NCOMMON1, NCOMMON2, VARIABLES1, VARIABLES2) constraint where NCOMMON1 and NCOMMON2 are both set to 0.

MiniZinc ([http://www.minizinc.org/](http://www.minizinc.org/)) has a DISJOINT constraint between two set variables rather than between two collections of variables.

Algorithm

Let us note:

• \( n_1 \) the minimum number of distinct values taken by the variables of the collection VARIABLES1.
• \( n_2 \) the minimum number of distinct values taken by the variables of the collection VARIABLES2.
• \( n_{12} \) the maximum number of distinct values taken by the union of the variables of VARIABLES1 and VARIABLES2.

One invariant to maintain for the DISJOINT constraint is \( n_1 + n_2 \leq n_{12} \). A lower bound of \( n_1 \) and \( n_2 \) can be obtained by using the algorithms provided in [29, 46]. An exact upper bound of \( n_{12} \) can be computed by using a bipartite matching algorithm.

Systems

DISJOINT in MiniZinc.

Used in

K_DISJOINT.

See also

generalisation: DISJOINT_TASKS (variable replaced by task).
implies: ALLDIFFERENT_ON_INTERSECTION, LEX_DIFFERENT.
system of constraints: K_DISJOINT.

Keywords

classifier of a constraint: disequality, automaton, automaton with array of counters.
constraint arguments: constraint between two collections of variables.
constraint type: value constraint.
filtering: bipartite matching.
modelling: empty intersection.
### Graph model

The graph model `PRODUCT` is used in order to generate the arcs of the graph between all variables of `VARIABLES1` and all variables of `VARIABLES2`. Since we use the graph property $NARC = 0$ the final graph will be empty. Figure 5.301 shows the initial graph associated with the `Example` slot. Since we use the $NARC = 0$ graph property the final graph is empty.

![Initial graph of the DISJOINT constraint](image)

**Figure 5.301:** Initial graph of the DISJOINT constraint (the final graph is empty)

### Signature

Since 0 is the smallest number of arcs of the final graph we can rewrite $NARC = 0$ to $NARC \leq 0$. This leads to simplify $NARC$ to $NARC$. 
Automaton

Figure 5.302 depicts the automaton associated with the DISJOINT constraint. To each variable VAR1 of the collection VARIABLES1 corresponds a signature variable $S_i$ that is equal to 0. To each variable VAR2 of the collection VARIABLES2 corresponds a signature variable $S_i + |\text{VARIABLES1}|$ that is equal to 1.

$$\begin{align*}
\{ & C[j] \leftarrow 0, \\
& D[j] \leftarrow 0 \} \quad \text{0,} \\
& \{ C[\text{VAR1}_i] \leftarrow C[\text{VAR1}_i] + 1 \} \\
& \{ D[\text{VAR2}_i] \leftarrow D[\text{VAR2}_i] + 1 \}
\end{align*}$$

$$\begin{align*}
\{ & D[\text{VAR2}_i] \leftarrow D[\text{VAR2}_i] + 1 \}
\end{align*}$$

Figure 5.302: Automaton of the DISJOINT(VARIABLES1, VARIABLES2) constraint, where state $s$ handles variables of the collection VARIABLES1 and state $t$ handles variables of the collection VARIABLES2.
### 5.126 DISJOINT_SBOXES

#### Description

**Origin**
Geometry, derived from [349]

**Constraint**

\[
\text{DISJOINT}_\text{SBOXES}(K, \text{DIMS}, \text{OBJECTS}, \text{SBOXES})
\]

**Synonym**
DISJOINT.

**Types**

- **VARIABLES**: \(\text{collection}(v \rightarrow \text{dvar})\)
- **INTEGERS**: \(\text{collection}(v \rightarrow \text{int})\)
- **POSITIVES**: \(\text{collection}(v \rightarrow \text{int})\)

**Arguments**

- \(K\) : \(\text{int}\)
- \(\text{DIMS}\) : \(\text{sint}\)
- \(\text{OBJECTS}\) : \(\text{collection}(\text{oid} \rightarrow \text{int}, \text{sid} \rightarrow \text{dvar}, x \rightarrow \text{VARIABLES})\)
- \(\text{SBOXES}\) : \(\text{collection}(\text{sid} \rightarrow \text{int}, t \rightarrow \text{INTEGERS}, l \rightarrow \text{POSITIVES})\)

**Restrictions**

- \([\text{VARIABLES}] \geq 1\)
- \([\text{INTEGERS}] \geq 1\)
- \([\text{POSITIVES}] \geq 1\)
- \(\text{required(\text{VARIABLES}, v)}\)
- \(\text{required(\text{INTEGERS}, v)}\)
- \(\text{required(\text{POSITIVES}, v)}\)
- \(\text{POSITIVES}.v > 0\)
- \(K > 0\)
- \(\text{DIMS} \geq 0\)
- \(\text{DIMS} < K\)
- \(\text{increasing_seq(\text{OBJECTS}, [\text{oid}])}\)
- \(\text{required(\text{OBJECTS}, [\text{oid}, \text{sid}, x])}\)
- \(\text{OBJECTS}.\text{oid} \geq 1\)
- \(\text{OBJECTS}.\text{oid} \leq |\text{OBJECTS}|\)
- \(\text{OBJECTS}.\text{sid} \geq 1\)
- \(\text{OBJECTS}.\text{sid} \leq |\text{SBOXES}|\)
- \(\text{SBOXES} \geq 1\)
- \(\text{required(\text{SBOXES}, [\text{sid}, t, l])}\)
- \(\text{SBOXES}.\text{sid} \geq 1\)
- \(\text{SBOXES}.\text{sid} \leq |\text{SBOXES}|\)
- \(\text{do\_not\_overlap(\text{SBOXES})}\)
Holds if, for each pair of objects \((O_i, O_j)\), \(i \neq j\), \(O_i\) and \(O_j\) are disjoint with respect to a set of dimensions depicted by \(DIMS\). \(O_i\) and \(O_j\) are objects that take a shape among a set of shapes. Each shape is defined as a finite set of shifted boxes, where each shifted box is described by a box in a \(K\)-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a shifted box is an entity defined by its shape id \(sid\), shift offset \(t\), and sizes \(l\). Then, a shape is defined as the union of shifted boxes sharing the same shape id. An object is an entity defined by its unique object identifier \(oid\), shape id \(sid\) and origin \(x\).

Two objects \(O_i\) and object \(O_j\) are disjoint with respect to a set of dimensions depicted by \(DIMS\) if and only if for all shifted box \(s_i\) associated with \(O_i\) and for all shifted box \(s_j\) associated with \(O_j\) there exists at least one dimension \(d \in DIMS\) such that (1) the origin of \(s_i\) in dimension \(d\) is strictly greater than the end of \(s_j\) in dimension \(d\), or (2) the origin of \(s_j\) in dimension \(d\) is strictly greater than the end of \(s_i\) in dimension \(d\).

Example

\[
\begin{pmatrix}
2, \{0, 1\}, \\
oid = 1 \quad sid = 1 \quad x = \{1, 1\}, \\
oid = 2 \quad sid = 2 \quad x = \{4, 1\}, \\
oid = 3 \quad sid = 4 \quad x = \{2, 4\}
\end{pmatrix}
\]

Figure 5.303 shows the objects of the example. Since these objects are pairwise disjoint the DISJOINT_SBOXES constraint holds.

Typical

| \(|OBJECTS| > 1

Symmetries

- Items of OBJECTS are permutable.
- Items of SBOXES are permutable.
- SBOXES.l.v can be decreased to any value \(\geq 1\).

Arg. properties

Suffix-contractible wrt. OBJECTS.

Remark

One of the eight relations of the Region Connection Calculus [349]. Unlike the NON_OVERLAP_SBOXES constraint, which just prevents objects from overlapping, the DISJOINT_SBOXES constraint in addition enforces that borders and corners of objects are not directly in contact.

See also

common keyword: CONTAINS_SBOXES, COVEREDBY_SBOXES, COVERS_SBOXES, EQUAL_SBOXES, INSIDE_SBOXES, MEET_SBOXES (rcc8), NON_OVERLAP_SBOXES (geometrical constraint, logic), OVERLAP_SBOXES (rcc8).

implies: NON_OVERLAP_SBOXES.
Figure 5.303: (D) the three mutually disjoint objects $O_1$, $O_2$, $O_3$ of the Example slot respectively assigned shapes $S_1$, $S_2$, $S_4$; (A), (B), (C) shapes $S_1$, $S_2$, $S_3$ and $S_4$ are respectively made up from 1, 3, 3 and 1 disjoint shifted box.

**Keywords**

- **constraint type:** logic.
- **geometry:** geometrical constraint, rcc8.
- **miscellaneous:** obscure.
Logic

- $\text{origin}(O1, S1, D) \overset{\text{def}}{=} O1.x(D) + S1.t(D)$
- $\text{end}(O1, S1, D) \overset{\text{def}}{=} O1.x(D) + S1.t(D) + S1.l(D)$
- $\text{disjoint_sboxes}(\text{Dims}, O1, S1, O2, S2) \overset{\text{def}}{=} \exists D \in \text{Dims} \bigg( \begin{array}{c} \text{origin}(O1, S1, D) > \text{end}(O2, S2, D) \\ \text{origin}(O2, S2, D) > \text{end}(O1, S1, D) \end{array} \bigg)$
- $\text{disjoint_objects}(\text{Dims}, O1, O2) \overset{\text{def}}{=} \forall S1 \in \text{sboxes}(\text{[O1.sid]}) \forall S2 \in \text{sboxes}(\text{[O2.sid]}) \\text{disjoint_sboxes}(\text{Dims}, O1, S1, O2, S2)$
- $\text{all_disjoint}(\text{Dims}, \text{OIDS}) \overset{\text{def}}{=} \forall O1 \in \text{objects}(\text{OIDS}) \forall O2 \in \text{objects}(\text{OIDS}) \quad O1.\text{oid} < \Rightarrow O2.\text{oid} \\text{disjoint_objects}(\text{Dims}, O1, O2)$
- $\text{all_disjoint}(\text{DIMENSIONS}, \text{OIDS})$
5.127 DISJOINT_TASKS

### Origin
Derived from DISJOINT.

### Constraint
DISJOINT_TASKS(TASKS1, TASKS2)

### Arguments
| TASKS1 | : collection(origin−dvar, duration−dvar, end−dvar) |
| TASKS2 | : collection(origin−dvar, duration−dvar, end−dvar) |

### Restrictions
- require_at_least(2, TASKS1, [origin, duration, end])
- TASKS1.duration ≥ 0
- TASKS1.origin ≤ TASKS1.end
- require_at_least(2, TASKS2, [origin, duration, end])
- TASKS2.duration ≥ 0
- TASKS2.origin ≤ TASKS2.end

### Purpose
Each task of the collection TASKS1 should not overlap any task of the collection TASKS2. Two tasks overlap if they have an intersection that is strictly greater than zero.

### Example
```
\[
\left(\begin{array}{ccc}
\text{origin} & \text{duration} & \text{end} \\
-6 & -5 & -11 \\
-8 & -2 & -10 \\
-2 & -2 & -4 \\
-3 & -3 & -6 \\
-12 & -1 & -13
\end{array}\right)
\]
```

Figure 5.304 displays the two groups of tasks (i.e., the tasks of TASKS1 and the tasks of TASKS2). Since no task of the first group overlaps any task of the second group, the DISJOINT_TASKS constraint holds.

### Typical
- |TASKS1| > 1
- TASKS1.duration > 0
- |TASKS2| > 1
- TASKS2.duration > 0

### Symmetries
- Arguments are permutable w.r.t. permutation (TASKS1, TASKS2).
- Items of TASKS1 are permutable.
- Items of TASKS2 are permutable.
- One and the same constant can be added to the origin and end attributes of all items of TASKS1 and TASKS2.

### Arg. properties
- Contractible wrt. TASKS1.
- Contractible wrt. TASKS2.
DISJOINT_TASKS

Figure 5.304: The DISJOINT_TASKS solution to the Example slot with at most one distinct colour in parallel (tasks in TASKS1 have the pink colour, while tasks in TASKS2 have the blue colour)

Remark
Despite the fact that this is not an uncommon constraint, it cannot be modelled in a compact way with a single CUMULATIVE constraint. But it can be expressed by using the COLOURED_CUMULATIVE constraint: We assign a first colour to the tasks of TASKS1 as well as a second distinct colour to the tasks of TASKS2. Finally we set up a limit of 1 for the maximum number of distinct colours allowed at each time point.

Reformulation
The DISJOINT_TASKS constraint can be expressed in term of |TASKS1| · |TASKS2| reified constraints. For each task TASKS1[i] (i ∈ [1,|TASKS1|]) and for each task TASKS2[j] (j ∈ [1,|TASKS2|]) we generate a reified constraint of the form TASKS1[i].end ≤ TASKS2[j].origin ∨ TASKS2[j].end ≤ TASKS1[i].origin. In addition we also state for each task an arithmetic constraint that states that the end of a task is equal to the sum of its origin and its duration.

Systems
DISJOINT in Choco.

See also
generalisation: COLOURED_CUMULATIVE (tasks colours and limit on maximum number of colours in parallel are explicitly given).
specialisation: DISJOINT (task replaced by variable).

Keywords
constraint type: scheduling constraint, temporal constraint.
geometry: non-overlapping.
Graph model: *PRODUCT* is used in order to generate the arcs of the graph between all the tasks of the collection *TASKS1* and all tasks of the collection *TASKS2*. The first two graph constraints respectively enforce for each task of *TASKS1* and *TASKS2* the fact that the end of a task is equal to the sum of its origin and its duration. The arc constraint of the third graph constraint depicts the fact that two tasks overlap. Therefore, since we use the graph property \( \text{NARC} = 0 \) the final graph associated with the third graph constraint will be empty and no task of *TASKS1* will overlap any task of *TASKS2*. Figure 5.305 shows the initial graph of the third graph constraint associated with the *Example* slot. Because of the graph property \( \text{NARC} = 0 \) the corresponding final graph is empty.

**Signature**

Since *TASKS1* is the maximum number of arcs of the final graph associated with the first graph constraint we can rewrite \( \text{NARC} = |\text{TASKS1}| \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).

We can apply a similar remark for the second graph constraint.

Finally, since 0 is the smallest number of arcs of the final graph we can rewrite \( \text{NARC} = 0 \) to \( \text{NARC} \leq 0 \). This leads to simplify \( \text{NARC} \) to \( \text{NARC} \).
Figure 5.305: Initial graph of the DISJOINT_TASKS constraint (the final graph is empty)
5.128 DISJUNCTIVE

Origin [100]

Constraint DISJUNCTIVE(TASKS)

Synonym ONE_MACHINE

Argument TASKS : collection(origin-dvar, duration-dvar)

Restrictions required(TASKS,[origin, duration]) TASKS.duration ≥ 0

Purpose All the tasks of the collection TASKS that have a duration strictly greater than 0 should not overlap.

Example

\[
\begin{align*}
\text{origin} - 1 & \quad \text{duration} - 3, \\
\text{origin} - 2 & \quad \text{duration} - 0, \\
\text{origin} - 7 & \quad \text{duration} - 2, \\
\text{origin} - 4 & \quad \text{duration} - 1
\end{align*}
\]

Figure 5.306 shows the tasks with non-zero duration of the example. Since these tasks do not overlap the DISJUNCTIVE constraint holds.

Figure 5.306: Tasks with non-zero duration of the Example slot

All solutions Figure 5.307 gives all solutions to the following non ground instance of the DISJUNCTIVE constraint: \( O_1 \in [2,5], D_1 \in [2,4], O_2 \in [2,4], D_2 \in [1,6], O_3 \in [3,6], D_3 \in [4,4], O_4 \in [2,7], D_4 \in [1,3], \text{DISJUNCTIVE}((O_1, D_1, O_2, D_2, O_3, D_3, O_4, D_4)).\)

Typical \( |\text{TASKS}| > 2 \) \( \text{TASKS}.\text{duration} ≥ 1 \)

Symmetries

- Items of TASKS are permutable.
- TASKS.duration can be decreased to any value \( ≥ 0 \).
- One and the same constant can be added to the origin attribute of all items of TASKS.
The DISJUNCTIVE constraint occurs in many resource scheduling problems in order to model a resource that cannot be shared. This means that tasks using this resource cannot overlap in time. Quite often DISJUNCTIVE constraints are used together with precedence constraints. A precedence constraint between two tasks models the fact that the processing of a task has to be postponed until another task is completed. Such mix of disjunctive and precedence constraints occurs, for example, in job-shop problems.

A soft version of this constraint, under the hypothesis that all durations are fixed, was presented by P. Baptiste et al. in [19]. In this context the goal was to perform as many tasks as possible within their respective due-dates.

Within the context of linear programming [226, page 386] provides several relaxations of the DISJUNCTIVE constraint.

Some solvers use in a pre-processing phase, while stating precedence and cumulative constraints, an algorithm for automatically extracting large cliques [97] from a set of tasks that should not pairwise overlap (i.e., two tasks $t_i$ and $t_j$ can not overlap either, because $t_i$ ends before the start of $t_j$, either because the sum of resource consumption of $t_i$ and $t_j$ exceeds the capacity of a cumulative resource that both tasks use) in order to state DISJUNCTIVE constraints.

We have four main families of methods for handling the DISJUNCTIVE constraint:

- Methods based on the compulsory part [261] of the tasks (also called time-tabling methods). These methods determine the time slots which for sure are occupied by a given task, and propagate back this information to the attributes of each task (i.e.,
the origin and the duration). Because of their simplicities, these methods have been originally used for handling the DISJUNCTIVE constraint. Even if they propagate less than the other methods they can in practice handle a large number of tasks. To our best knowledge no efficient incremental algorithm devoted to this problem was published up to now (i.e., September 2006).

- Methods based on constructive disjunction. The idea is to try out each alternative of a disjunction (e.g., given two tasks $t_1$ and $t_2$ that should not overlap, we successively assume that $t_1$ finishes before $t_2$, and that $t_2$ finishes before $t_1$) and to remove values that were pruned in both alternatives.

- Methods based on edge-finding. Given a set of tasks $\mathcal{T}$, edge-finding determines that some task must, can, or cannot execute first or last in $\mathcal{T}$. Efficient edge-finding algorithms for handling the DISJUNCTIVE constraint were originally described in [101, 102] and more recently in [443, 315].

- Methods that, for any task $t$, consider the maximal number of tasks that can end up before the start of task $t$ as well as the maximal number of tasks that can start after the end of task $t$ [453].

All these methods are usually used for adjusting the minimum and maximum values of the variables of the DISJUNCTIVE constraint. However some systems use these methods for pruning the full domain of the variables. Finally, Jackson priority rule [236] provides a necessary condition [102] for the DISJUNCTIVE constraint. Given a set of tasks $\mathcal{T}$, it consists to progressively schedule all tasks of $\mathcal{T}$ in the following way:

- It assigns to the first possible time point (i.e., the earliest start of all tasks of $\mathcal{T}$) the available task with minimal latest end. In this context, available means a task for which the earliest start is less than or equal to the considered time point.

- It continues by considering the next time point until all the tasks are completely scheduled.

In 2014, assuming that the tasks are sorted, and using a union-find data structure, linear-time filtering algorithms [169] wrt the number of tasks were obtained for time-tableing, overload check, and detectable precedences.

**Systems**

DISJUNCTIVE in Choco, UNARY in Gecode.

**See also**

- common keyword: CALENDAR, DISJ, DISJUNCTIVE_OR_SAME_END, DISJUNCTIVE_OR_SAME_START (scheduling constraint).

\text{tasks1}\cdot\text{origin} + \text{tasks1}\cdot\text{duration} &\leq \text{tasks2}\cdot\text{origin}, \\
\text{tasks2}\cdot\text{origin} + \text{tasks2}\cdot\text{duration} &\leq \text{tasks1}\cdot\text{origin} \end{aligned} \]
Graph property(ies) | \( \text{NARC} = |\text{TASKS}| \ast (|\text{TASKS}| - 1)/2 \)

Graph model

We generate a \textit{clique} with a non-overlapping constraint between each pair of distinct tasks and state that the number of arcs of the final graph should be equal to the number of arcs of the initial graph.

Parts (A) and (B) of Figure 5.308 respectively show the initial and final graph associated with the \textbf{Example} slot. The \textit{DISJUNCTIVE} constraint holds since all the arcs of the initial graph belong to the final graph: all the non-overlapping constraints holds.

![Figure 5.308: Initial and final graph of the DISJUNCTIVE constraint](image)

Quiz

**EXERCISE 1 (checking whether a ground instance holds or not)**

A. Does the constraint \textit{DISJUNCTIVE}(\{(2, 2), (4, 5), (8, 2)\}) hold?
B. Does the constraint \textit{DISJUNCTIVE}(\{(1, 3), (4, 4), (8, 2)\}) hold?
C. Does the constraint \textit{DISJUNCTIVE}(\{(3, 2), (4, 0), (7, 3)\}) hold?

*Hint: go back to the definition of \textit{DISJUNCTIVE}.*
SOLUTION TO EXERCISE 1

A. No, since tasks 2 and 3 overlap at instant 8.

B. Yes, since the three tasks do not overlap:
   - Tasks 1 and 2 do not overlap since task 1 ends before task 2,
   - Tasks 1 and 3 do not overlap since task 1 ends before task 3,
   - Tasks 2 and 3 do not overlap since task 2 ends before task 3.

C. Yes, since tasks 1 and 3 do not overlap and since the duration of task 2 is zero.
### 5.129 DISJUNCTIVE\_OR\_SAME\_END

<td></td>
</tr>
<tr>
<td>Restrictions</td>
<td>required(TASKS,[origin,duration]) TASKS.duration ≥ 0</td>
<td></td>
</tr>
</tbody>
</table>

**Purpose**

All pairs of tasks of the collection TASKS that have a duration strictly greater than 0 should either not overlap either have the same end, i.e. \( \forall i \in [1, |\text{TASKS}|], \forall j \in [i + 1, |\text{TASKS}|] : \text{TASKS}[i].\text{duration} = 0 \lor \text{TASKS}[j].\text{duration} = 0 \lor \text{TASKS}[i].\text{origin} + \text{TASKS}[i].\text{duration} \leq \text{TASKS}[j].\text{origin} \lor \text{TASKS}[j].\text{origin} + \text{TASKS}[j].\text{duration} \leq \text{TASKS}[i].\text{origin} \lor \text{TASKS}[i].\text{origin} + \text{TASKS}[i].\text{duration} = \text{TASKS}[j].\text{origin} + \text{TASKS}[j].\text{duration} \). One can use the sweep algorithm introduced in [42] to filter the origin of a task wrt all the sets of forbidden values issued from the other tasks.

**Example**

\[
\begin{pmatrix}
(\text{origin} - 4, \text{duration} - 3, \\
\text{origin} - 7, \text{duration} - 2, \\
\text{origin} - 5, \text{duration} - 2)
\end{pmatrix}
\]

Since the ends of the first and third tasks coincide, and since the second task does neither overlap the first task nor the third task, the DISJUNCTIVE\_OR\_SAME\_END constraint holds.

**Typical**

\(|\text{TASKS}| > 2 \\
\text{TASKS}.\text{duration} ≥ 1\)

**Symmetries**

- Items of TASKS are **permutable**.
- TASKS.duration can be **decreased** to any value \( ≥ 0 \).
- One and the same constant can be **added** to the origin attribute of all items of TASKS.

**Arg. properties**

**Contractible** wrt. TASKS.

**Algorithm**

Let \( o_k \) and \( d_k \) (with \( k \in [1, |\text{TASKS}|] \)) respectively denote the origin and the duration of the \( k^{th} \) task of the TASKS collection. The set of forbidden values for the origin of task \( j \) wrt task \( i \) (with \( i, j \in [1, |\text{TASKS}|], i \neq j \)) is defined by the union \( [o_i - d_j + 1, o_i + d_i - d_j - 1] \cup [o_j + d_i - d_j + 1, o_j + d_i - 1] \). One can use the sweep algorithm introduced in [42] to filter the origin of a task wrt all the sets of forbidden values issued from the other tasks.

Graph model

We generate a clique with a non-overlapping constraint or a same end constraint between each pair of distinct tasks and state that the number of arcs of the final graph should be equal to the number of arcs of the initial graph.

Parts (A) and (B) of Figure 5.309 respectively show the initial and final graph associated with the Example slot. The DISJUNCTIVE_OR_SAME_END constraint holds since all the arcs of the initial graph belong to the final graph.

![Diagram](image)

Figure 5.309: Initial and final graph of the DISJUNCTIVE_OR_SAME_END constraint
5.130 DISJUNCTIVE_ORSAME_START

**Origin**
Scheduling.

**Constraint**
\( \text{DISJUNCTIVE\_OR\_SAME\_START}(\text{TASKS}) \)

**Synonyms**
SAME\_START\_OR\_DISJUNCTIVE, NON\_OVERLAP\_OR\_SAME\_START, SAME\_START\_OR\_NON\_OVERLAP.

**Argument**
\( \text{TASKS} : \text{collection}(\text{origin}-\text{dvar}, \text{duration}-\text{dvar}) \)

**Restrictions**
\( \text{required}(\text{TASKS}, [\text{origin}, \text{duration}]) \)
\( \text{TASKS}.\text{duration} \geq 0 \)

**Purpose**
All pairs of tasks of the collection TASKS that have a duration strictly greater than 0 should either not overlap either have the same start, i.e. \( \forall i \in [1, |\text{TASKS}|], \forall j \in [i + 1, |\text{TASKS}|] : \text{TASKS}[i].\text{duration} \geq 0 \lor \text{TASKS}[j].\text{duration} \geq 0 \lor \text{TASKS}[i].\text{origin} + \text{TASKS}[i].\text{duration} \leq \text{TASKS}[j].\text{origin} \lor \text{TASKS}[j].\text{origin} + \text{TASKS}[j].\text{duration} \leq \text{TASKS}[i].\text{origin} \lor \text{TASKS}[i].\text{origin} \leq \text{TASKS}[j].\text{origin} \).

**Example**
\[
\left( \begin{array}{c}
\text{origin} - 4 & \text{duration} - 3, \\
\text{origin} - 7 & \text{duration} - 2, \\
\text{origin} - 4 & \text{duration} - 1 \\
\end{array} \right)
\]

Since the starts of the first and third tasks coincide, and since the second task does neither overlap the first task nor the third task, the DISJUNCTIVE\_OR\_SAME\_START constraint holds.

**Typical**
\( |\text{TASKS}| > 2 \)
\( \text{TASKS}.\text{duration} \geq 1 \)

**Symmetries**
- Items of TASKS are permutable.
- TASKS.duration can be decreased to any value \( \geq 0 \).
- One and the same constant can be added to the origin attribute of all items of TASKS.

**Arg. properties**
Contractible wrt. TASKS.

**Algorithm**
Let \( o_k \) and \( d_k \) (with \( k \in [1, |\text{TASKS}|] \)) respectively denote the origin and the duration of the \( k^{th} \) task of the TASKS collection. **constraint type**: arithmetic constraint, predefined constraint.

**modelling**: functional dependency.
DISTANCE

1157
5.132 DISTANCE_BETWEEN

Description

Origin
N. Beldiceanu

Constraint
DISTANCE_BETWEEN(DIST, VARIABLES1, VARIABLES2, CTR)

Synonym
DISTANCE.

Arguments
DIST : dvar
VARIABLES1 : collection(var–dvar)
VARIABLES2 : collection(var–dvar)
CTR : atom

Restrictions
DIST ≥ 0
DIST ≤ |VARIABLES1| * |VARIABLES2| − |VARIABLES1|
required(VARIABLES1, var)
required(VARIABLES2, var)
|VARIABLES1| = |VARIABLES2|
CTR ∈ [=, ≠, <, ≥, >, ≤]

Purpose
Let $U_i$ and $V_i$ be respectively the $i^{th}$ and $j^{th}$ variables ($i \neq j$) of the collection VARIABLES1. In a similar way, let $X_i$ and $Y_i$ be respectively the $i^{th}$ and $j^{th}$ variables ($i \neq j$) of the collection VARIABLES2. DIST is equal to the number of times one of the following mutually incompatible conditions are true:

- $U_i$ CTR $V_i$ holds and $X_i$ CTR $Y_i$ does not hold,
- $X_i$ CTR $Y_i$ holds and $U_i$ CTR $V_i$ does not hold.

Example

\[(2, (3, 4, 6, 2, 4), (2, 6, 9, 3, 6), <)\]

The DISTANCE_BETWEEN constraint holds since the following DIST = 2 conditions are verified:

Typical

DIST > 0
DIST < |VARIABLES1| * |VARIABLES2| − |VARIABLES1|
|VARIABLES1| > 1
CTR ∈ [=, ≠]
**Symmetries**

- Arguments are permutable w.r.t. permutation (DIST) (VARIABLES1, VARIABLES2) (CTR).
- Items of VARIABLES1 and VARIABLES2 are permutable (same permutation used).
- One and the same constant can be added to the var attribute of all items of VARIABLES1.
- One and the same constant can be added to the var attribute of all items of VARIABLES2.

**Arg. properties**

**Functional dependency**: DIST determined by VARIABLES1, VARIABLES2 and CTR.

**Usage**

Measure the distance between two sequences in terms of the number of constraint changes. This should be put in contrast to the number of value changes that is sometimes superficial.

**See also**

**common keyword**: DISTANCE\_CHANGE (*proximity constraint*).

**Keywords**

**constraint arguments**: pure functional dependency.
**constraint type**: proximity constraint.
**modelling**: functional dependency.
<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Graph model**

Within the Arc input(s) slot, the character / indicates that we generate two distinct graphs. The graph property DISTANCE measures the distance between two digraphs $G_1$ and $G_2$. This distance is defined as the sum of the following quantities:

- The number of arcs of $G_1$ that do not belong to $G_2$,
- The number of arcs of $G_2$ that do not belong to $G_1$.

Part (A) of Figure 5.311 gives the final graph associated with the sequence var-3, var-4, var-6, var-2, var-4 (i.e., the second argument of the constraint of the Example slot), while part (B) shows the final graph corresponding to var-2, var-6, var-9, var-3, var-6 (i.e., the third argument of the constraint of the Example slot). The two arc constraints that differ from one graph to the other are marked by a dotted line. The DISTANCE_BETWEEN constraint holds since between sequence var-3, var-4, var-6, var-2, var-4 and sequence var-2, var-6, var-9, var-3, var-6 there are $DIST = 2$ changes that respectively correspond to:

- Within the final graph associated with sequence var-3, var-4, var-6, var-2, var-4 the arc 4 → 1 (i.e., values 2 → 3) does not occur in the final graph associated with var-2, var-6, var-9, var-3, var-6,
- Within the final graph associated with sequence var-2, var-6, var-9, var-3, var-6 the arc 1 → 4 (i.e., values 2 → 3) does not occur in the final graph associated with var-3, var-4, var-6, var-2, var-4.

![Graph model](image)

DISTANCE BETWEEN

1161
### DISTANCE_CHANGE

#### Origin
Derived from `CHANGE`.

#### Constraint

\[
\text{DISTANCE}\_\text{CHANGE}(\text{DIST, VARIABLES1, VARIABLES2, CTR})
\]

#### Synonym

DISTANCE.

#### Arguments

- **DIST**: dvar
- **VARIABLES1**: collection(var–dvar)
- **VARIABLES2**: collection(var–dvar)
- **CTR**: atom

#### Restrictions

- \(\text{DIST} \geq 0\)
- \(\text{DIST} < |\text{VARIABLES1}|\)
- `required(VARIABLES1.var)`
- `required(VARIABLES2.var)`
- \(|\text{VARIABLES1}| = |\text{VARIABLES2}|\)
- \(\text{CTR} \in [\;=, \neq, <, \geq, >, \leq]\)

#### Purpose

DIST is equal to the number of times one of the following two conditions is true \((1 \leq i < n)\):

- **VARIABLES1[i].var** CTR **VARIABLES1[i + 1].var** holds and **VARIABLES2[i].var** CTR **VARIABLES2[i + 1].var** does not hold.
- **VARIABLES2[i].var** CTR **VARIABLES2[i + 1].var** holds and **VARIABLES1[i].var** CTR **VARIABLES1[i + 1].var** does not hold.

#### Example

\((1, (3, 3, 1, 2, 2), (4, 4, 3, 3), \neq)\)

The `DISTANCE_CHANGE` constraint holds since the following condition \((\text{DIST} = 1)\) is verified:

\[
\begin{cases}
\text{VARIABLES1[3].var} = 1 \neq \text{VARIABLES1[4].var} = 2 \\
\text{VARIABLES2[3].var} = 3 = \text{VARIABLES1[4].var} = 3
\end{cases}
\]

#### Typical

- \(\text{DIST} > 0\)
- \(|\text{VARIABLES1}| > 1\)
- \(\text{CTR} \in [\;=, \neq]\)

#### Symmetries

- Arguments are **permutable** w.r.t. permutation \((\text{DIST}) \) \((\text{VARIABLES1, VARIABLES2})\) \((\text{CTR})\).
- One and the same constant can be **added** to the \(\text{var}\) attribute of all items of \text{VARIABLES1}.
- One and the same constant can be **added** to the \(\text{var}\) attribute of all items of \text{VARIABLES2}.
Arg. properties  Functional dependency: DIST determined by VARIABLES1, VARIABLES2 and CTR.

Usage  Measure the distance between two sequences according to the CHANGE constraint.

Remark  We measure that distance with respect to a given constraint and not according to the fact that the variables are assigned distinct values.

See also  common keyword: DISTANCE_BETWEEN (proximity constraint).
root concept: CHANGE.

Keywords  characteristic of a constraint: automaton, automaton with counters.
constraint arguments: pure functional dependency.
constraint network structure: sliding cyclic(2) constraint network(2).
constraint type: proximity constraint.
modelling: functional dependency.
### Graph model

Within the **Arc input(s)** slot, the character / indicates that we generate two distinct graphs. The graph property **DISTANCE** measures the distance between two digraphs $G_1$ and $G_2$. This distance is defined as the sum of the following quantities:

- The number of arcs of $G_1$ that do not belong to $G_2$,
- The number of arcs of $G_2$ that do not belong to $G_1$.

Part (A) of Figure 5.312 gives the final graph associated with the sequence var-3, var-3, var-1, var-2, var-2 (i.e., the second argument of the constraint of the **Example** slot), while part (B) shows the final graph corresponding to var-4, var-4, var-3, var-3, var-3, var-3 (i.e., the third argument of the constraint of the **Example** slot). Since arc $3 \rightarrow 4$ belongs to the first final graph but not to the second one, the distance between the two final graphs is equal to 1.

![Figure 5.312: Final graphs of the DISTANCE_CHANGE constraint](image-url)
Figure 5.313 depicts the automaton associated with the DISTANCE_CHANGE constraint. Let \((\text{VAR}_1, \text{VAR}_{1+i})\) and \((\text{VAR}_2, \text{VAR}_{2+i})\) respectively be the \(i^{th}\) pairs of consecutive variables of the collections \(\text{VARIABLES}_1\) and \(\text{VARIABLES}_2\). To each quadruple \((\text{VAR}_1, \text{VAR}_{1+i}, \text{VAR}_2, \text{VAR}_{2+i})\) corresponds a 0-1 signature variable \(S_i\). The following signature constraint links these variables:

\[
((\text{VAR}_1 = \text{VAR}_{1+i}) \land (\text{VAR}_2 \neq \text{VAR}_{2+i})) \lor \\
((\text{VAR}_1 \neq \text{VAR}_{1+i}) \land (\text{VAR}_2 = \text{VAR}_{2+i})) \iff S_i.
\]

\[\{C \leftarrow 0\} \quad s \quad \{C \leftarrow C + 1\}\]

\[\text{DIST} = C\]

5.136 DOM_REACHABILITY

### Description

The `DOM_REACHABILITY` function is documented in [341].

### Arguments

- **SOURCE**: `int`  
- **FLOW_GRAPH**: `collection(index=int, succ=svar)`  
- **DOMINATOR_GRAPH**: `collection(index=int, succ=sint)`  
- **TRANSITIVE_CLOSURE_GRAPH**: `collection(index=int, succ=svar)`

### Restrictions

- **SOURCE**: $\geq 1$  
- **SOURCE**: $\leq |FLOW_GRAPH|$  
- **FLOW_GRAPH**: `required(FLOW_GRAPH, [index, succ])`  
- **FLOW_GRAPH**: `index \geq 1`  
- **FLOW_GRAPH**: `index \leq |FLOW_GRAPH|$  
- **FLOW_GRAPH**: `succ \geq 1`  
- **FLOW_GRAPH**: `succ \leq |FLOW_GRAPH|$  
- **DOMINATOR_GRAPH**: `distinct(FLOW_GRAPH, index)`  
- **DOMINATOR_GRAPH**: `required(DOMINATOR_GRAPH, [index, succ])`  
- **DOMINATOR_GRAPH**: `index \geq 1`  
- **DOMINATOR_GRAPH**: `index \leq |DOMINATOR_GRAPH|$`  
- **DOMINATOR_GRAPH**: `succ \geq 1`  
- **DOMINATOR_GRAPH**: `succ \leq |DOMINATOR_GRAPH|$`  
- **DOMINATOR_GRAPH**: `distinct(DOMINATOR_GRAPH, index)`  
- **TRANSITIVE_CLOSURE_GRAPH**: `required(TRANSITIVE_CLOSURE_GRAPH, [index, succ])`  
- **TRANSITIVE_CLOSURE_GRAPH**: `|TRANSITIVE_CLOSURE_GRAPH| = |FLOW_GRAPH|$`  
- **TRANSITIVE_CLOSURE_GRAPH**: `index \geq 1`  
- **TRANSITIVE_CLOSURE_GRAPH**: `index \leq |TRANSITIVE_CLOSURE_GRAPH|$`  
- **TRANSITIVE_CLOSURE_GRAPH**: `succ \geq 1`  
- **TRANSITIVE_CLOSURE_GRAPH**: `succ \leq |TRANSITIVE_CLOSURE_GRAPH|$`  
- **TRANSITIVE_CLOSURE_GRAPH**: `distinct(TRANSITIVE_CLOSURE_GRAPH, index)}`
Let \texttt{FLOW\_GRAPH}, \texttt{DOMINATOR\_GRAPH} and \texttt{TRANSITIVE\_CLOSURE\_GRAPH} be three directed graphs respectively called the \textit{flow graph}, the \textit{dominance graph} and the \textit{transitive closure graph} which all have the same vertices. In addition let \texttt{SOURCE} denote a vertex of the flow graph called the \textit{source node} (not necessarily a vertex with no incoming arcs). The \texttt{DOM\_REACHABILITY} constraint holds if and only if the flow graph (and its source node) verifies:

- The dominance relation expressed by the dominance graph (i.e., if there is an arc \((i, j)\) in the dominance graph then, within the flow graph, all the paths from the source node to \(j\) contain \(i\); note that when there is no path from the source node to \(j\) then any node dominates \(j\)).

- The transitive relation expressed by the transitive closure graph (i.e., if there is an arc \((i, j)\) in the transitive closure graph then there is also a path from \(i\) to \(j\) in the flow graph).

\textbf{Example}

\[
\begin{pmatrix}
\text{index} - 1 & \text{succ} = \{2\}, \\
\text{index} - 2 & \text{succ} = \{3, 4\}, \\
\text{index} - 3 & \text{succ} = \emptyset, \\
\text{index} - 4 & \text{succ} = \emptyset, \\
\text{index} - 1 & \text{succ} = \{2, 3, 4\}, \\
\text{index} - 2 & \text{succ} = \{3, 4\}, \\
\text{index} - 3 & \text{succ} = \emptyset, \\
\text{index} - 4 & \text{succ} = \emptyset, \\
\text{index} - 1 & \text{succ} = \{1, 2, 3, 4\}, \\
\text{index} - 2 & \text{succ} = \{2, 3, 4\}, \\
\text{index} - 3 & \text{succ} = \{3\}, \\
\text{index} - 4 & \text{succ} = \{4\}
\end{pmatrix}
\]

The flow graph, the dominance graph and the transitive closure graph corresponding to the second, third and fourth arguments of the \texttt{DOM\_REACHABILITY} constraint are respectively depicted by parts \textit{(A)}, \textit{(B)} and \textit{(C)} of Figure 5.315. The \texttt{DOM\_REACHABILITY} holds since the following conditions hold.

- The dominance relation expressed by the dominance graph is verified:
  - Since \((1, 2)\) belongs to the dominance graph all the paths from 1 to 2 in the flow graph pass through 1.
  - Since \((1, 3)\) belongs to the dominance graph all the paths from 1 to 3 in the flow graph pass through 1.
  - Since \((1, 4)\) belongs to the dominance graph all the paths from 1 to 4 in the flow graph pass through 1.
  - Since \((2, 3)\) belongs to the dominance graph all the paths from 1 to 3 in the flow graph pass through 1.
  - Since \((2, 4)\) belongs to the dominance graph all the paths from 1 to 4 in the flow graph pass through 1.

- The graph depicted by the fourth argument of the \texttt{DOM\_REACHABILITY} constraint (i.e., \texttt{TRANSITIVE\_CLOSURE\_GRAPH}) is the transitive closure of the graph depicted by the second argument (i.e., \texttt{FLOW\_GRAPH}).
Figure 5.315: (A) Flow graph, (B) dominance graph and (C) transitive closure graph of the Example slot (taken from [339, page 40])

Typical

\[ |\text{FLOW}\_\text{GRAPH}| > 2 \]

Symmetries

- Items of FLOW\_\text{GRAPH} are \textit{permutable}.
- Items of DOMINATOR\_\text{GRAPH} are \textit{permutable}.
- Items of TRANSITIVE\_\text{CLOSURE}\_\text{GRAPH} are \textit{permutable}.

Usage

The DOM\_\text{REACHABILITY} constraint was introduced in order to solve reachability problems (e.g., disjoint paths, simple path with mandatory nodes).

Remark

Within the name DOM\_\text{REACHABILITY}, DOM stands for \textit{domination}. In the context of path problems SOURCE refers to the start of the path we want to build.

Algorithm

It was shown in [339] that, finding out whether a DOM\_\text{REACHABILITY} constraint has a solution or not is NP-hard. This was achieved by reduction to disjoint paths problem [194].

The first implementation [340] of the DOM\_\text{REACHABILITY} constraint was done in Mozart [130]. Later on, a second implementation [339] was done in Gecode [385]. Both implementations consist of the following two parts:

- Algorithms [373] for maintaining the lower bound of the transitive closure graph.
- Algorithms for maintaining the upper bound of the transitive closure graph, while respecting the dominance constraints [203].

5.137 DOMAIN

Origin
Domain definition.

Constraint
\text{DOMAIN}(\text{VARIABLES}, \text{LOW}, \text{UP})

Synonym
\text{DOM}.

Arguments
\begin{itemize}
\item \texttt{VARIABLES} : \texttt{collection(var-dvar)}
\item \texttt{LOW} : \texttt{int}
\item \texttt{UP} : \texttt{int}
\end{itemize}

Restrictions
\begin{itemize}
\item \texttt{required(\text{VARIABLES}, \text{var})}
\item \texttt{LOW \leq UP}
\end{itemize}

Purpose
Enforce all the variables of the collection \texttt{VARIABLES} to take a value within the interval \([\text{LOW}, \text{UP}].\)

Example
\((\langle 2, 8, 2 \rangle, 1, 9)\)

The \texttt{DOMAIN} constraint holds since all the values 2, 8 and 2 of its first argument are greater than or equal to its second argument \texttt{LOW} = 1 and less than or equal to its third argument \texttt{UP} = 9.

Typical
\begin{itemize}
\item \texttt{\mid VARIABLES\mid > 1}
\item \texttt{LOW < UP}
\end{itemize}

Symmetries
\begin{itemize}
\item Items of \texttt{VARIABLES} are \texttt{permutable}.
\item An occurrence of a value of \texttt{VARIABLES.var} can be \texttt{replaced} by any other value in \([\text{LOW}, \text{UP}].\)
\item \texttt{LOW} can be \texttt{decreased}.
\item \texttt{UP} can be \texttt{increased}.
\item One and the same constant can be \texttt{added} to the \texttt{var} attribute of all items of \texttt{VARIABLES} as well as to \texttt{LOW} and \texttt{UP}.
\end{itemize}

Arg. properties
\texttt{Contractible} wrt. \texttt{VARIABLES}.

Remark
The \texttt{DOMAIN} constraint is called \texttt{DOM} in \texttt{Gecode} (http://www.gecode.org/).

Reformulation
The \texttt{DOMAIN(\langle \text{var} - V_1, \text{var} - V_2, \ldots, \text{var} - V_{\mid VARIABLES\mid} \rangle, \text{LOW}, \text{UP})} constraint can be expressed in term of the conjunction
\begin{itemize}
\item \texttt{V_1 \geq \text{LOW} \land V_1 \leq \text{UP}}.
\item \texttt{V_2 \geq \text{LOW} \land V_2 \leq \text{UP}}.
\end{itemize}
\begin{itemize}
\item \ldots \ldots \ldots \ldots \\
\item \texttt{V_{\mid VARIABLES\mid} \geq \text{LOW} \land V_{\mid VARIABLES\mid} \leq \text{UP}}.
\end{itemize}

### Derived Collection

\[
\text{col}(\text{VALUE}\cdot\text{collection}(\text{var01}\cdot\text{int},\text{value}\cdot\text{dvar}),
\text{item}(\text{var01}\cdot1,\text{value}\cdot\text{VAR}))
\]

### Arc input(s)
- **VALUE** values

### Arc generator
- \(PRODUCT\) \(\rightarrow\) \(\text{collection}(\text{value},\text{values})\)

### Arc arity
- 2

### Arc constraint(s)
- \(\text{value}.\text{value} = \text{values}.\text{value} \iff \text{values}.\text{var01} = 1\)

### Graph property(ies)
- \(\text{NARC} = |\text{VALUES}|\)

### Graph model

The `DOMAIN_CONSTRANT` constraint is modelled with the following bipartite graph:

- The first class of vertices corresponds to a single vertex containing the domain variable.
- The second class of vertices contains one vertex for each item of the collection `VALUES`.

\(PRODUCT\) is used in order to generate the arcs of the graph. In our context it takes a collection with a single item \(\langle \text{var01}\cdot1,\text{value}\cdot\text{VAR} \rangle\) and the collection `VALUES`.

The arc constraint between the variable `VAR` and one potential value \(v\) expresses the following:

- If the 0-1 variable associated with \(v\) is equal to 1, \(VAR\) is equal to \(v\).
- Otherwise, if the 0-1 variable associated with \(v\) is equal to 0, \(VAR\) is not equal to \(v\).

Since all arc constraints should hold the final graph contains exactly \(|\text{VALUES}|\) arcs.

Parts (A) and (B) of Figure 5.316 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the arcs of the final graph are stressed in bold.

### Signature

Since the number of arcs of the initial graph is equal to `VALUES` the maximum number of arcs of the final graph is also equal to `VALUES`. Therefore we can rewrite the graph property \(\text{NARC} = |\text{VALUES}|\) to \(\text{NARC} \geq |\text{VALUES}|\). This leads to simplify \(\text{NARC}\) to \(\text{NARC}\).
Figure 5.316: Initial and final graph of the DOMAIN_CONSTRAINT constraint
Automaton

Figure 5.317 depicts the automaton associated with the DOMAIN_CONSTRAINT constraint. Let VAR01i and VALUEi respectively be the var01 and the value attributes of the i-th item of the VALUES collection. To each triple (VAR, VAR01i, VALUEi) corresponds a 0-1 signature variable Si as well as the following signature constraint: ((VAR = VALUEi) ⇔ VAR01i) ⇔ Si.

Figure 5.317: Automaton of the DOMAIN_CONSTRAINT constraint

Figure 5.318: Hypergraph of the reformulation corresponding to the automaton of the DOMAIN_CONSTRAINT constraint: since all states variables Q0, Q1, ..., Qn are fixed to the unique state s of the automaton, the transitions constraints involve only a single variable and the constraint network is Berge-acyclic
5.139 ELEM

### Origin
Derived from `ELEMENT`.

### Constraint
`ELEM(ITEM, TABLE)`

### Usual name
`ELEMENT`

### Synonyms
`NTH, ARRAY`.

### Arguments
- `ITEM` : `collection(index−dvar, value−dvar)`
- `TABLE` : `collection(index−int, value−dvar)`

### Restrictions
- `required(ITEM, [index, value])`
- `ITEM.index ≥ 1`
- `ITEM.index ≤ |TABLE|`
- `|ITEM| = 1`
- `|TABLE| > 0`
- `required(TABLE, [index, value])`
- `TABLE.index ≥ 1`
- `TABLE.index ≤ |TABLE|`
- `distinct(TABLE, index)`

### Purpose
`ITEM` is equal to one of the entries of the table `TABLE`.

### Example
```
(index - 3 value - 2),
   index - 1 value - 6,
   index - 2 value - 9,
   index - 3 value - 2,
   index - 4 value - 9
```

The `ELEM` constraint holds since its first argument `ITEM` corresponds to the third item of the `TABLE` collection.

### Typical
- `|TABLE| > 1`
- `range(TABLE.value) > 1`

### Symmetries
- Items of `TABLE` are permutable.
- All occurrences of two distinct values in `ITEM.value` or `TABLE.value` can be swapped; all occurrences of a value in `ITEM.value` or `TABLE.value` can be renamed to any unused value.

### Arg. properties
Functional dependency: `ITEM.value` determined by `ITEM.index` and `TABLE`.
Usage

Makes the link between the discrete decision variable INDEX and the variable VALUE according to a given table of values TABLE. We now give five typical uses of the ELEM constraint.

1. In some problems we may have to represent a function \( y = f(x) \) (with \( x \in [1, m] \)).

In this context we generate the following ELEM constraint where INDEX is a domain variable taking its values in \( \{1, 2, \ldots, m\} \):

\[
\text{ELEM} \left( \begin{array}{c}
\langle \text{index} - x, \text{value} - y \rangle , \\
\langle \text{index} - 1, \text{value} - f(1) \rangle , \\
\langle \text{index} - 2, \text{value} - f(2) \rangle , \\
\vdots \\
\langle \text{index} - m, \text{value} - f(m) \rangle
\end{array} \right)
\]

Figure 5.319: \( y = x^3 \) (1 \( \leq \) \( x \) \( \leq \) 3)

As an example, consider the problem of finding the smallest integer that can be de-
1. In some optimisation problems a classical use of the ELEM constraint can be used for representing the function \( y = x^3 \) (Figure 5.319). The unique solution 1729 = 12^3 + 1^3 = 10^3 + 9^3 can be obtained by the following set of constraints:

\[
\begin{align*}
\text{ELEM} & \{(\text{index} - x_1 \text{ value} - y_1), \\
& (\text{index} - 1 \text{ value} - 1, \text{index} - 2 \text{ value} - 8, \ldots, \text{index} - 20 \text{ value} - 8000)\} \\
\text{ELEM} & \{(\text{index} - x_2 \text{ value} - y_2), \\
& (\text{index} - 1 \text{ value} - 1, \text{index} - 2 \text{ value} - 8, \ldots, \text{index} - 20 \text{ value} - 8000)\} \\
\text{ELEM} & \{(\text{index} - x_3 \text{ value} - y_3), \\
& (\text{index} - 1 \text{ value} - 1, \text{index} - 2 \text{ value} - 8, \ldots, \text{index} - 20 \text{ value} - 8000)\} \\
\text{ELEM} & \{(\text{index} - x_4 \text{ value} - y_4), \\
& (\text{index} - 1 \text{ value} - 1, \text{index} - 2 \text{ value} - 8, \ldots, \text{index} - 20 \text{ value} - 8000)\} \\
y_1 + y_2 = y_3 + y_4 \\
x_1 < x_2 \\
x_3 < x_4 \\
x_1 < x_3
\end{align*}
\]

The last three inequalities constraints in the conjunction are used for breaking symmetries. The constraints \( x_1 < x_2 \) and \( x_3 < x_4 \) respectively order the pairs of variables \((x_1, x_2)\) and \((x_3, x_4)\) from which the sums \( x_1^3 + x_2^3 \) and \( x_3^3 + x_4^3 \) are generated. Finally, the inequality \( x_1 < x_3 \) enforces a lexicographic ordering between the two pairs of variables \((x_1, x_2)\) and \((x_3, x_4)\).

2. In some optimisation problems a classical use of the ELEM constraint consists expressing the link between a discrete choice and its corresponding cost. For each discrete choice we create an ELEM constraint of the form:

\[
\text{ELEM} \left\{ \begin{array}{c}
\langle \text{index} - \text{Choice value} - \text{Cost} \rangle, \\
\text{index} - 1 \text{ value} - \text{Cost}_1, \\
\text{index} - 2 \text{ value} - \text{Cost}_2, \\
\vdots \\
\text{index} - m \text{ value} - \text{Cost}_m \end{array} \right\}
\]

where:

- \text{Choice} is a domain variable that indicates which alternative will be finally selected.
- \text{Cost} is a domain variable that corresponds to the cost of the decision associated with the value of the \text{Choice} variable.
- \text{Cost}_1, \text{Cost}_2, \ldots, \text{Cost}_m are the respective costs associated with the alternatives 1, 2, \ldots, m.

3. In some problems we need to express a disjunction of the form \( \text{VAR} = \text{VAR}_1 \lor \text{VAR} = \text{VAR}_2 \lor \cdots \lor \text{VAR} = \text{VAR}_n \). This can be directly reformulated as the following ELEM constraint, where \text{INDEX} is a domain variable taking its value in the finite set \{1, 2, \ldots, n\} and where the \text{TABLE} argument corresponds to the domain variables \text{VAR}_1, \text{VAR}_2, \ldots, \text{VAR}_n:

\[
\text{ELEM} \left\{ \begin{array}{c}
\langle \text{index} - \text{INDEX value} - \text{VAR} \rangle, \\
\text{index} - 1 \text{ value} - \text{VAR}_1, \\
\text{index} - 2 \text{ value} - \text{VAR}_2, \\
\vdots \\
\text{index} - n \text{ value} - \text{VAR}_n \end{array} \right\}
\]
4. In some scheduling problems the duration of a task depends on the machine where the task will be assigned in final schedule. In this case we generate for each task an ELEM constraint of the following form:

\[
\text{ELEM} \left( \langle \text{index} - \text{Machine}, \text{value} - \text{Duration} \rangle, \right.
\]

\[
\left. \langle \text{index} - 1, \text{value} - \text{Dur}_1 \rangle, \langle \text{index} - 2, \text{value} - \text{Dur}_2 \rangle, \ldots, \langle \text{index} - m, \text{value} - \text{Dur}_m \rangle \right) \]

where:

- \text{Machine} is a domain variable that indicates the resource to which the task will be assigned,
- \text{Duration} is a domain variable that corresponds to the duration of the task,
- \text{Dur}_1, \text{Dur}_2, \ldots, \text{Dur}_m are the respective duration of the task according to the hypothesis that it runs on machine 1, 2 or \( m \).

5. In some vehicle routing problems we typically use the ELEM constraint to express the distance between location \( i \) and the next location visited by a vehicle. For this purpose we generate for each location \( i \) an ELEM constraint of the form:

\[
\text{ELEM} \left( \langle \text{index} - \text{Next}_i, \text{value} - \text{distance}_i \rangle, \right.
\]

\[
\left. \langle \text{index} - 1, \text{value} - \text{Dist}_{i1} \rangle, \langle \text{index} - 2, \text{value} - \text{Dist}_{i2} \rangle, \ldots, \langle \text{index} - m, \text{value} - \text{Dist}_{im} \rangle \right) \]

where:

- \text{Next}_i is a domain variable that gives the index of the location the vehicle will visit just after location \( i \).
• distance, is a domain variable that corresponds to the distance between location i and the location the vehicle will visit just after,
• Dist, Dist, ..., Dist are the respective distances between location i and locations 1, 2, ..., m.

An other example where the table argument corresponds to domain variables is described in the keyword entry assignment to the same set of values.

Remark
Originally, the parameters of the ELEM constraint had the form ELEM(INDEX, TABLE, VALUE), where INDEX and VALUE were two domain variables and TABLE was a list of non-negative integers.

Within some systems (e.g., Gecode), the index of the first entry of the table TABLE corresponds to 0 rather than to 1.

When the first entry of the table TABLE corresponds to a value p that is different from 1 we can still use the ELEM constraint. We use the reformulation \( I = J - p + 1 \land \) ELEM(INDEX - I, VALUE - V, TABLE), where I and J are domain variables respectively ranging from 1 to |TABLE| and from p to p + |TABLE| - 1.

Systems
NTH in Choco, ELEMENT in Gecode, ELEMENT in JaCoP, ELEMENT in SICStus.

See also
common keyword: ELEMENT_FROM_TO, ELEMENT_MATRIX, ELEMENT_PRODUCT, ELEMENT_SPARSE (array constraint), ELEMENTS_SPARSE, STAGE_ELEMENT (data constraint).

implied by: ELEMENT.

implies: ELEMENT (single item replaced by two variables), ELEMENT_GREATEREQ, ELEMENT_LESSEQ, ELEMENTS.

system of constraints: ELEMENTS.

uses in its reformulation: ELEMENTS_ALLDIFFERENT.

modelling exercises: assignment to the same set of values, sequence dependent set-up, zebra puzzle.

puzzles: zebra puzzle.

Cond. implications
ELEM(ITEM, TABLE)
with TABLE.value ≥ 0
implies BIN_PACKING_CAPA(TABLE, ITEM).
Arc input(s) | ITEM TABLE
---|---
Arc generator | PRODUCT \( \rightarrow \) collection(item, table)
Arc arity | 2
Arc constraint(s) | • item.index = table.index
| • item.value = table.value
Graph property(ies) | NARC = 1

Graph model
We regroup the INDEX and VALUE parameters of the original ELEMENT constraint ELEMENT(INDEX, TABLE, VALUE) into the parameter ITEM. We also make explicit the different indices of the table TABLE.

Parts (A) and (B) of Figure 5.321 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the unique arc of the final graph is stressed in bold.

![Graph model](image)

Figure 5.321: Initial and final graph of the ELEM constraint

Signature
Since all the index attributes of TABLE are distinct and because of the first condition of the arc constraint the final graph cannot have more than one arc. Therefore we can rewrite NARC = 1 to NARC \( \geq \) 1 and simplify NARC to NARC.
Automaton

Figure 5.322 depicts the automaton associated with the ELEM constraint. Let INDEX and VALUE respectively be the index and the value attributes of the unique item of the ITEM collection. Let INDEXᵢ and VALUEᵢ respectively be the index and the value attributes of item i of the TABLE collection. To each quadruple (INDEX, VALUE, INDEXᵢ, VALUEᵢ) corresponds a 0-1 signature variable $Sᵢ$ as well as the following signature constraint: $\left( \left( \text{INDEX} = \text{INDEXᵢ} \right) \land \left( \text{VALUE} = \text{VALUEᵢ} \right) \right) \Leftrightarrow Sᵢ$.

Figure 5.322: Automaton of the ELEM(ITEM, TABLE) constraint (once one finds the right item – index and value – in the table, one switches from the initial state $s$ to the accepting state $t$)

Figure 5.323: Hypergraph of the reformulation corresponding to the automaton of the ELEM constraint
5.140  ELEM_FROM_TO

Origin
Derived from ELEM.

Constraint
ELEM_FROM_TO(ITEM, TABLE)

Synonym
ELEMENT_FROM_TO.

Arguments
ITEM : collection
  ⟨from−dvar, cst_from−int, to−dvar, cst_to−int, value−dvar⟩
TABLE : collection(index−int, value−dvar)

Restrictions
required(ITEM, [from.cst_from.to, cst_to.value])
ITEM.from ≥ 1
ITEM.from ≤ |TABLE|
ITEM.to ≥ 1
ITEM.to ≤ |TABLE|
ITEM.from ≤ ITEM.to
|ITEM| = 1
required(TABLE, [index, value])
TABLE.index ≥ 1
TABLE.index ≤ |TABLE|
increasing_seq(TABLE, [index])

Let FROM, CST_FROM, TO, CST_TO, VALUE respectively denote the attributes
ITEM[1].from, ITEM[1].cst_from, ITEM[1].to, ITEM[1].cst_to, ITEM[1].value of the
unique item of the ITEM collection.

Beside imposing the fact that FROM ≤ TO and that both FROM and TO are assigned a
value in [1, |TABLE|], the ELEM_FROM_TO constraint forces the following condition: All
entries of the TABLE collection from position max(1, FROM + CST_FROM) to position
min(|TABLE|, TO + CST_TO) are equal to VALUE. When max(1, FROM + CST_FROM) is
strictly greater than min(|TABLE|, TO + CST_TO) the constraint holds no matter what
value is assigned to VALUE.

Example
\[
\begin{pmatrix}
\text{from} - 1 \\
\text{index} - 1 \\
\text{index} - 2 \\
\text{index} - 3 \\
\text{index} - 4 \\
\text{index} - 5 \\
\end{pmatrix}
\begin{pmatrix}
\text{cst_from} - 1 \\
\text{value} - 6 \\
\text{value} - 2 \\
\text{value} - 2 \\
\text{value} - 9 \\
\text{value} - 9 \\
\end{pmatrix}
\begin{pmatrix}
\text{from} - 4 \\
\text{cst_to} - 1 \\
\text{value} - 2 \\
\text{value} - 2 \\
\text{value} - 9 \\
\end{pmatrix}
\]

The ELEM_FROM_TO constraint holds since all entries between position
max(1, FROM + CST_FROM) = max(1, 1 + 1) = 2 and position min(TABLE, TO + CST_TO) = min(5, 4 − 1) = 3 are equal to 2.

Typical

| ITEM CST_FROM ≥ 0 |
| ITEM CST_FROM ≤ 1 |
| ITEM CST_TO ≥ −1 |
| ITEM CST_TO ≤ 1 |
| \(|TABLE| > 1 |
| range(TABLE.value) > 1 |

Symmetry

All occurrences of two distinct values in ITEM.value or TABLE.value can be swapped; all occurrences of a value in ITEM.value or TABLE.value can be renamed to any unused value.

Usage

Given an array \(t[1..n]\) of integers (i.e., an array of integers for which the entries are defined between 1 and n), the ELEM_FROM_TO constraint is useful, for example, for encoding expressions of the form \(\exists i \in [1, n], \forall j \in [i + 1, n] \mid t[i] = 0\). Note that, when the interval \([i + 1, n]\) is empty, the condition \(\forall j \in [i + 1, n] \mid t[i] = 0\) is satisfied and i is equal to n. This example is encoded by using an ELEM_FROM_TO constraint and by respectively setting:

- FROM to i, where i is a variable that is assigned a value from interval [1, n],
- CST_FROM to constant 1,
- TO to n, the index of the last entry of the array \(t[1..n]\),
- CST_TO to constant 0,
- VALUE to 0, the value we are looking for.
- TABLE to the array of integers \(t[1..n]\).

Finally, note that j is not used at all.

**common keyword:** ELEM, ELEMENT (array constraint).

Keywords

**characteristic of a constraint:** automaton, automaton without counters, reified automaton constraint.

**constraint type:** data constraint.

**filtering:** arc-consistency.

**modelling:** array constraint, table, variable indexing, variable subscript.
Figure 5.324 depicts the automaton associated with the ELEM_FROM_TO constraint.

Let us first introduce some notations:

- Let \( n \) denote the number of items of the TABLE collection.
- Let \( INDEX_i \) and \( VALUE_i \) respectively be the index and the value attributes of the \( i \)th item of the TABLE collection.
- Let \( FROM[I].from \), \( ITEM[I].cst_from \), \( ITEM[I].to \), \( ITEM[I].cst_to \), \( ITEM[I].value \) respectively denote the attributes \( ITEM[I].from, ITEM[I].cst_from, ITEM[I].to, ITEM[I].cst_to, ITEM[I].value \) of the unique item of the ITEM collection.
- Let \( IN \) be a shortcut for condition \( 1 \leq FROM \land FROM \leq TO \land TO \leq n \).
- Let \( F \) and \( T \) respectively denote the quantities \( \max(1, FROM + CST_FROM) \) and \( \min(|TABLE|, TO + CST_TO) \).

To each septuple \((FROM, TO, F, T, VALUE, INDEX_i, VALUE_i)\) corresponds a signature variable \( S_i \) as well as the following signature constraint:

\[
\begin{align*}
& (IN \land F > T) \quad \Leftrightarrow \quad S_i = 0 \land \\
& (IN \land F \leq T \land F > INDEX_i) \quad \Leftrightarrow \quad S_i = 1 \land \\
& (IN \land F \leq T \land T < INDEX_i) \quad \Leftrightarrow \quad S_i = 2 \land \\
& (IN \land F \leq T \land F \leq INDEX_i \land INDEX_i \leq T \land VALUE = VALUE_i) \quad \Leftrightarrow \quad S_i = 3 \land \\
& (IN \land F \leq T \land F \leq INDEX_i \land INDEX_i \leq T \land VALUE \neq VALUE_i) \quad \Leftrightarrow \quad S_i = 4
\end{align*}
\]

5.141 ELEMENT

<table>
<thead>
<tr>
<th>Description</th>
<th>Links</th>
<th>Graph</th>
<th>Automaton</th>
</tr>
</thead>
</table>

**Origin**

[429]

**Constraint**

ELEMENT(INDEX, TABLE, VALUE)

**Synonyms**

NTH, ELEMENT_VAR, ARRAY.

**Arguments**

- INDEX : dvar
- TABLE : collection(value−dvar)
- VALUE : dvar

**Restrictions**

- INDEX ≥ 1
- INDEX ≤ |TABLE|
- |TABLE| > 0
  required(TABLE, value)

**Purpose**

VALUE is equal to the INDEX\textsuperscript{th} item of TABLE, i.e. VALUE = TABLE[INDEX].

**Example**

\[ (3, (6, 9, 2, 9), 2) \]

The ELEMENT constraint holds since its third argument VALUE = 2 is equal to the 3\textsuperscript{rd} (INDEX = 3) item of the collection (6, 9, 2, 9).

**All solutions**

Figure 5.326 gives all solutions to the following non ground instance of the ELEMENT constraint: I ∈ [3, 6], V ∈ [1, 9], ELEMENT(I, {4, 8, 1, 0, 3, 3, 4, 3, 3}, V).

\[ \begin{array}{c}
\text{(3, \{41, 82, 13, 04, 34, 36, 77, 38\}, 1)} \\
\text{(5, \{41, 82, 13, 04, 35, 36, 47, 38\}, 3)} \\
\text{(6, \{41, 82, 13, 04, 35, 36, 47, 38\}, 3)} \\
\end{array} \]

</tr>
</tbody>
</table>

\[ |TABLE| > 1 \]

\[ \text{range}(TABLE.value) > 1 \]

**Symmetry**

All occurrences of two distinct values in TABLE.value or VALUE can be swapped; all occurrences of a value in TABLE.value or VALUE can be renamed to any unused value.
Arg. properties

- Functional dependency: VALUE determined by INDEX and TABLE.
- Suffix-extensible wrt. TABLE.

Usage

See Usage slot of ELEM.

Remark

In the original ELEMENT constraint of CHIP the index attribute was not explicitly present in the table of values. It was implicitly defined as the position of a value in the previous table.

Within some systems (e.g., Gecode), the index of the first entry of the table TABLE corresponds to 0 rather than to 1.

When the first entry of the table TABLE corresponds to a value \( p \) that is different from 1 we can still use the ELEMENT constraint. We use the reformulation \( I = J - p + 1 \land \) ELEMENT\((I, \text{TABLE}, V)\), where \( I \) and \( J \) are domain variables respectively ranging from 1 to \( |\text{TABLE}| \) and from \( p \) to \( p + |\text{TABLE}| - 1 \).

The ELEMENT constraint is called NTH in Choco (http://choco.sourceforge.net/). It is also sometimes called ELEMENT_VAR when the second argument corresponds to a table of variables.

The CASE constraint \([108]\) is a generalisation of the ELEMENT constraint, where the table is replaced by a directed acyclic graph describing the set of solutions: there is a one to one correspondence between the solutions and the paths from the unique source of the dag to its leaves.

Systems

NTH in Choco, ELEMENT in Gecode, ELEMENT in JaCoP, ELEMENT in MiniZinc, ELEMENT in SICStus.

Derived Collection

\[
\text{col}(\text{ITEM}\rightarrow\text{collection}(\text{index-dvar},\text{value-dvar}), \{\text{item}[\text{index} = \text{INDEX}, \text{value} = \text{VALUE}]\} )
\]

Arc input(s)
ITEM TABLE

Arc generator
\[\text{PRODUCT} \rightarrow \text{collection}(\text{item}, \text{table})\]

Arc arity
2

Arc constraint(s)
- item.index = table.key
- item.value = table.value

Graph property(ies)
NARC = 1

Graph model

The original \text{ELEMENT} constraint with three arguments. We use the derived collection \text{ITEM} for putting together the \text{INDEX} and \text{VALUE} parameters of the \text{ELEMENT} constraint. Within the arc constraint we use the implicit attribute \text{key} that associates to each item of a collection its position within the collection.

Parts (A) and (B) of Figure 5.327 respectively show the initial and final graph associated with the \textbf{Example} slot. Since we use the \text{NARC} graph property, the unique arc of the final graph is stressed in bold.

![Graph](image)

Figure 5.327: Initial and final graph of the \text{ELEMENT} constraint

Signature

Because of the first condition of the arc constraint the final graph cannot have more than one arc. Therefore we can rewrite \text{NARC} = 1 to \text{NARC} \geq 1 and simplify \text{NARC} to \text{NARC}.
Automaton

Figure 5.328 depicts the automaton associated with the \textsc{element} constraint. Let \textsc{value}_i be the \textsc{value} attribute of item \textsc{index}_i of the \textsc{table} collection. To each triple \((\textsc{index}_i, \textsc{value}_i, \textsc{value}_i)\) corresponds a 0-1 signature variable \(S_i\) as well as the following signature constraint: \((\textsc{index}_i = i \land \textsc{value}_i = \textsc{value}_i) \Leftrightarrow S_i\).

Quiz

**EXERCISE 1** (checking whether a ground instance holds or not)

A. Does the constraint \textsc{element}(0, \langle 5, 1, 4, 8, 1 \rangle, 5) hold?

B. Does the constraint \textsc{element}(3, \langle 8, 2, 4, 3 \rangle, 4) hold?

C. Does the constraint \textsc{element}(5, \langle 0, 1, 2, 3, 4, 5 \rangle, 5) hold?

\(^{a}\text{Hint: go back to the definition of \textsc{element}.}\)
**EXERCISE 2 (finding all solutions)**

Give all the solutions to the constraint:
\[
\begin{aligned}
I & \in [2, 6], \\
V & \in [0, 5], \\
\text{ELEMENT}(I, (0, 2, 9, 5, 2, 3, 9), V).
\end{aligned}
\]

*Hint: follow the order induced by the functional dependency between the arguments of Element, enumerate solutions in lexicographic order.*

**EXERCISE 3 (finding all solutions)**

Give all the solutions to the constraint:
\[
\begin{aligned}
I & \in [2, 3], \\
V_1 & \in [5, 5], V_2 \in [3, 5], V_3 \in [0, 3], \\
V & \in [1, 2], \\
\text{ELEMENT}(I, V_1, V_2, V_3, V).
\end{aligned}
\]

*Hint: first find the feasible values of the first argument, then enumerate solutions in lexicographic order.*

**EXERCISE 4 (identifying infeasible values)**

Identify all variable-value pairs \((V_i, \text{val})\) \((0 \leq i \leq 3)\), such that the following constraint has no solution when value \(\text{val}\) is assigned to variable \(V_i\):
\[
\begin{aligned}
V_0 & \in [2, 3], \quad V_1 \in [2, 4], \\
V_2 & \in [0, 4], \quad V_3 \in [3, 5], \\
\text{ELEMENT}(V_0, (V_1, 0, V_2, 6), V_3).
\end{aligned}
\]

*Hint: first find the feasible values of the first argument, then filter the other variables.*

**EXERCISE 5 (variable-based degree of violation)**

Compute the variable-based degree of violation\(^*\) of the following constraints:
\[\text{A. ELEMENT}(0, (2, 2, 2, 2), 2),\]
\[\text{B. ELEMENT}(3, (3, 1, 5, 2, 7), 4),\]
\[\text{C. ELEMENT}(8, (5, 5, 8, 5, 0, 7), 2).\]

*Hint: take advantage of the functional dependency.

\(^*\)Given a constraint for which all variables are fixed, the variable-based degree of violation is the minimum number of variables to assign differently in order to satisfy the constraint.
EXERCISE 6 (using entailment for counting)*

A. Given an \( \text{ELEMENT}(i, (t_1, t_2, \ldots, t_n), v) \) constraint where \( i, t_1, t_2, \ldots, t_n, v \) are variables, what is the minimum number of variables to fix in order to achieve entailment? We assume that the constraint has at least one solution.

B. Exploit entailment in order to compute the number of solutions to the constraint \( i \in [1, 3], v_1 \in [0, 1], v_2 \in [1, 9], v_3 \in [3, 5], v \in [2, 7], \text{ELEMENT}(i, (v_1, v_2, v_3), v) \).

*Hint: take advantage of the functional dependency, use a case analysis on the first argument.  
*A constraint is entailed if and only if it is for sure satisfied even though some of its variables are not fixed.

---

EXERCISE 7 (modelling with an unconstrained index)*

What does the \( \text{ELEMENT} \) constraint model when its first argument, the index, is unconstrained?

*Hint: how would one define the set of solutions of the third argument?

---

EXERCISE 8 (modelling an index starting at 0)*

Given a table \( t \) whose entries are indexed at \([0, n]\) model the requirement \( v = t[i] \).

*Hint: make a shift.

---

EXERCISE 9 (modelling indirection)*

Given a table \( t \) whose entries vary between 1 and 9, model the requirement \( v = t[t[i]] \) as one or several constraints. What is the implicit assumption we have on the entries of the table?

*Hint: use more than one constraint.

---

SOLUTION TO EXERCISE 1

A. No, since value the first argument starts at index 1.

B. Yes, since the third entry of the table is equal to 4.

C. No, since the fifth entry is equal to 4 (and not to 5).
SOLUTION TO EXERCISE 2

The three solutions

<table>
<thead>
<tr>
<th>I</th>
<th>V</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( (0, 2, 9, 5, 9, 2, 3, 9), 2 )</td>
</tr>
<tr>
<td>2</td>
<td>( (0, 2, 9, 5, 9, 2, 3, 9), 2 )</td>
</tr>
<tr>
<td>3</td>
<td>( (0, 2, 9, 5, 9, 2, 3, 9), 2 )</td>
</tr>
</tbody>
</table>

1. The active entries of the table are located between index 2 and 6, as shown in bold by \( (0, 2, 9, 5, 9, 2, 3, 9) \).

2. Among these entries we restrict ourselves to those entries for which the value is located in the domain of variable \( V \), i.e. in interval \([0, 5]\). The remaining entries are shown in bold, i.e. \( (0, 2, 9, 5, 9, 2, 3, 9) \).

3. This leads to the three solutions \( I = 2 \ V = 2 \), \( I = 4 \ V = 5 \) and \( I = 6 \ V = 2 \).

SOLUTION TO EXERCISE 3

The six solutions

<table>
<thead>
<tr>
<th>I</th>
<th>V</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>( (3, 5, 9, 3, 1), 1 )</td>
</tr>
<tr>
<td>2</td>
<td>( (3, 5, 9, 3, 2), 2 )</td>
</tr>
<tr>
<td>3</td>
<td>( (3, 5, 9, 3, 1), 1 )</td>
</tr>
<tr>
<td>4</td>
<td>( (3, 5, 9, 3, 2), 2 )</td>
</tr>
<tr>
<td>5</td>
<td>( (3, 5, 9, 3, 1), 1 )</td>
</tr>
<tr>
<td>6</td>
<td>( (3, 5, 9, 3, 2), 2 )</td>
</tr>
</tbody>
</table>

1. Since the domain of \( V_2 \) which is located at the second entry of the table does not intersect the domain of \( V \) (the third argument), the index variable \( I \) (the first argument) can not be assigned value 2, and is therefore fixed to 3.

2. Since \( I \) is fixed to 3 we have that \( V = V_3 \). Consequently \( V \) and \( V_3 \) are assigned a same value that belongs to the intersection of their respective domains, i.e. \([0, 3] \cap [1, 2] = [1, 2]\).
1. In part (A) we give the initial domains of the index variable \(V_0\), of the first and third entries of the table \((V_1, V_2)\), and of the third argument of the ELEMENT constraint \(V_3\).

2. In part (B) we prune the index variable \(V_0\). On the one hand, it can not be assigned value 2 since the second entry of the table is set to 0, and 0 does not belong to the domain of \(V_3\), see \(\times\). On the other hand, it can be assigned value 3 since \(\text{dom}(V_2) \cap \text{dom}(V_3) \neq \emptyset\).

3. Finally in part (C) we remove those values that contradict the fact that \(V_2 = V_3\), see \(\times\).
SOLUTION TO EXERCISE 5

A. The degree of violation is equal to 1 since we only need to change the index from 0 (because 0 is not an allowed value for the index) to any integer value in $[1, 4]$.

\[ \text{ELEMENT}(1, (2, 2, 2), 2) \]

B. The degree of violation is equal to 1 since we only need to change the third entry of the table to 4 (or to switch the third argument from 4 to 5).

\[ \text{ELEMENT}(3, (3, 1, 5, 2, 7), 4) \]

C. The degree of violation is equal to 2 since we need to change both the index (the table has only 7 entries) and the third argument (value 2 does not occur in the table). Rather than changing the third argument, we may change an entry of the table (e.g., if we set the index to 3 we set the third entry of the table to 2).

\[ \text{ELEMENT}(8, (5, 5, 8, 5, 0, 7), 2) \]

SOLUTION TO EXERCISE 6

A. We need to fix 3 variables in the following way:

(i) The first argument, the index $i$, is fixed to a value $\alpha$ ($1 \leq \alpha \leq n$) such that $\text{dom}(t_\alpha) \cap \text{dom}(v) \neq \emptyset$.

(ii) We fix the third argument $v$ to a value $\beta$ in $\text{dom}(t_\alpha) \cap \text{dom}(v)$.

(iii) We fix $t_\alpha$ to $\beta$.

B. We have 90 solutions depending on whether $i = 1$, $i = 2$, or $i = 3$ (and $v = v_i$):

(i) $|\text{dom}(v) \cap \text{dom}(v_1)| \cdot |\text{dom}(v_2)| \cdot |\text{dom}(v_3)| = 0 \cdot 9 \cdot 3 = 0$.

(ii) $|\text{dom}(v) \cap \text{dom}(v_2)| \cdot |\text{dom}(v_1)| \cdot |\text{dom}(v_3)| = 6 \cdot 2 \cdot 3 = 36$.

(iii) $|\text{dom}(v) \cap \text{dom}(v_3)| \cdot |\text{dom}(v_1)| \cdot |\text{dom}(v_2)| = 3 \cdot 2 \cdot 9 = 54$.

SOLUTION TO EXERCISE 7

Given a table $t$ of $n$ entries $t[1], t[2], \ldots, t[n]$, ELEMENT models a disjunction stating that the third argument $v$ is equal to one of the values that can be assigned to one of the variables of the table, i.e. $v = t[1] \lor v = t[2] \lor \cdots \lor v = t[n]$. 
SOLUTION TO EXERCISE 8

The requirement \( v = t[i] \) can be modelled as the conjunction of the two constraints \( j = i + 1 \), \( \text{ELEMENT}(j, \langle t[0], t[1], \ldots, t[n] \rangle, v) \).

SOLUTION TO EXERCISE 9

The requirement \( v = t[t[i]] \) can be modelled as the conjunction of two \text{ELEMENT} constraints sharing the same table, namely:

\[ \text{ELEMENT}(i, \{t[1], t[2], \ldots, t[9]\}, j) \leftarrow \text{inner indirection } t[t[i]] \]
\[ \text{ELEMENT}(j, \{t[1], t[2], \ldots, t[9]\}, v) \leftarrow \text{outer indirection } t[t[i]] \]

The second \text{ELEMENT} constraint assumes that \( j \) corresponds to a valid index of the table, i.e., a value between 1 and 9.
5.142 ELEMENT_GREATEREQ

Origin

[312]

Constraint

ELEMENT_GREATEREQ(ITEM, TABLE)

Arguments

ITEM : collection(index−dvar, value−dvar)
TABLE : collection(index−int, value−int)

Restrictions

required(ITEM, [index, value])
ITEM.index ≥ 1
ITEM.index ≤ |TABLE|
|ITEM| = 1
|TABLE| > 0
required(TABLE, [index, value])
TABLE.index ≥ 1
TABLE.index ≤ |TABLE|
distinct(TABLE, index)

Purpose

ITEM[1].value is greater than or equal to one of the entries (i.e., the value attribute) of the table TABLE.

Example

\[
\begin{pmatrix}
\langle \text{index} - 1, \text{value} - 8 \rangle, \\
\langle \text{index} - 2, \text{value} - 9 \rangle, \\
\langle \text{index} - 3, \text{value} - 2 \rangle, \\
\langle \text{index} - 4, \text{value} - 9 \rangle
\end{pmatrix}
\]

The ELEMENT_GREATEREQ constraint holds since ITEM[1].value = 8 is greater than or equal to TABLE[ITEM[1].index].value = TABLE[1].value = 6.

Typical

|TABLE| > 1
range(TABLE.value) > 1

Symmetries

- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEM.value or TABLE.value can be swapped; all occurrences of a value in ITEM.value or TABLE.value can be renamed to any unused value.

Usage

Used for modelling variable subscripts in linear constraints [312].

Reformulation

By introducing an extra variable VAL, the ELEMENT_GREATEREQ((\langle \text{index} - INDEX\ value - VALUE \rangle, TABLE)) constraint can be expressed in term of an ELEM((\langle \text{index} - INDEX\ value - VALUE \rangle, TABLE)) constraint and of an inequality constraint VALUE ≥ VAL.

ITEM.index ≤ |TABLE|
|ITEM| = 1
|TABLE| > 0
required(TABLE, [index, value])
TABLE.index ≥ 1
TABLE.index ≤ |TABLE|
distinct(TABLE, index)

**Purpose**

ITEM[1].value is less than or equal to one of the entries (i.e., the value attribute) of the table TABLE.

**Example**

\[
\begin{pmatrix}
\langle \text{index} - 3 \, \text{value} - 1 \rangle, \\
\langle \text{index} - 1 \, \text{value} - 6 \rangle, \\
\langle \text{index} - 2 \, \text{value} - 9 \rangle, \\
\langle \text{index} - 3 \, \text{value} - 2 \rangle, \\
\langle \text{index} - 4 \, \text{value} - 9 \rangle
\end{pmatrix}
\]

The ELEMENT_LESSEQ constraint holds since ITEM[1].value = 1 is less than or equal to TABLE[ITEM[1].index].value = TABLE[3].value = 2.

**Typical**

|TABLE| > 1
range(TABLE.value) > 1

**Symmetries**

- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEM.value or TABLE.value can be swapped; all occurrences of a value in ITEM.value or TABLE.value can be renamed to any unused value.

**Usage**

Used for modelling variable subscripts in linear constraints [312].

**Reformulation**

By introducing an extra variable VAL, the ELEMENT_LESSEQ((index − INDEX value − VALUE), TABLE) constraint can be expressed in term of an ELEM((index − INDEX value − VAL), TABLE) constraint and of an inequality constraint VALUE ≤ VAL.
See also

common keyword: ELEMENT, ELEMENT_GREATEREQ, ELEMENT_PRODUCT (array constraint).

implied by: ELEM.

Keywords

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint.

constraint arguments: binary constraint.

constraint network structure: centered cyclic(2) constraint network(1).

constraint type: data constraint.

filtering: linear programming, arc-consistency.

modelling: array constraint, table, variable subscript, variable indexing.

Cond. implications

\[
\text{ELEMENT}_{LESSEQ}(\text{ITEM, TABLE})
\]

with \( \text{minval(ITEM.value)} > 0 \)

and \( \text{TABLE.value} > 0 \)

implies \( \text{BIN\_PACKING\_CAPA}(\text{BINS : TABLE, ITEMS : ITEM}) \).
**Arc input(s)**

ITEM TABLE

**Arc generator**

\[ \text{PRODUCT} \rightarrow \text{collection}(\text{item}, \text{table}) \]

**Arc arity**

2

**Arc constraint(s)**

- \( \text{item.index} = \text{table.index} \)
- \( \text{item.value} \leq \text{table.value} \)

**Graph property(ies)**

\( \text{NARC} = 1 \)

**Graph model**

Similar to the ELEMENT constraint except that the equality constraint of the second condition of the arc constraint is replaced by a less than or equal to constraint.

Parts (A) and (B) of Figure 5.333 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the unique arc of the final graph is stressed in bold.

![Diagram](attachment:image.png)

**Signature**

Since all the index attributes of TABLE are distinct and because of the first arc constraint the final graph cannot have more than one arc. Therefore we can rewrite \( \text{NARC} = 1 \) to \( \text{NARC} \geq 1 \) and simplify \( \text{NARC} \) to \( \text{NARC} \).
Automaton

Figure 5.334 depicts the automaton associated with the ELEMENT_LESSEQ constraint. Let INDEX and VALUE respectively be the index and the value attributes of the unique item of the ITEM collection. Let INDEX_i and VALUE_i respectively be the index and the value attributes of the i-th item of the TABLE collection. To each quadruple (INDEX, VALUE, INDEX_i, VALUE_i) corresponds a 0-1 signature variable $S_i$ as well as the following signature constraint: $((\text{INDEX} = \text{INDEX}_i) \land (\text{VALUE} \leq \text{VALUE}_i)) \Leftrightarrow S_i$.

Figure 5.335: Hypergraph of the reformulation corresponding to the automaton of the ELEMENT_LESSEQ constraint
5.144 ELEMENT_MATRIX

Origin
CHIP

Constraint
ELEMENT_MATRIX(MAX_I, MAX_J, INDEX_I, INDEX_J, MATRIX, VALUE)

Synonyms
ELEM_MATRIX, MATRIX.

Arguments
MAX_I : int
MAX_J : int
INDEX_I : dvar
INDEX_J : dvar
MATRIX : collection(i−int,j−int,v−int)
VALUE : dvar

Restrictions
MAX_I ≥ 1
MAX_J ≥ 1
INDEX_I ≥ 1
INDEX_I ≤ MAX_I
INDEX_J ≥ 1
INDEX_J ≤ MAX_J
required(MATRIX,[i,j,v])
increasing_seq(MATRIX,[i,j])
MATRIX.i ≥ 1
MATRIX.i ≤ MAX_I
MATRIX.j ≥ 1
MATRIX.j ≤ MAX_J
|MATRIX| = MAX_I * MAX_J

Purpose
The MATRIX collection corresponds to the two-dimensional matrix MATRIX[1..MAX_I, 1..MAX_J]. VALUE is equal to the entry MATRIX[INDEX_I, INDEX_J] of the previous matrix.

Example
\[
\begin{pmatrix}
\begin{array}{ccc}
i-1 & j-1 & v-4, \\
i-1 & j-2 & v-1, \\
i-1 & j-3 & v-7, \\
i-2 & j-1 & v-1, \\
i-2 & j-2 & v-0, \\
i-2 & j-3 & v-8, \\
i-3 & j-1 & v-3, \\
i-3 & j-2 & v-2, \\
i-3 & j-3 & v-1, \\
i-4 & j-1 & v-0, \\
i-4 & j-2 & v-0, \\
i-4 & j-3 & v-6
\end{array}
\end{pmatrix}, 7
\]
The `ELEMENT_MATRIX` constraint holds since its last argument `VALUE = 7` is equal to the \( v \) attribute of the \( k \)th item of the `MATRIX` collection such that `MATRIX[k]i = INDEX_I = 1` and `MATRIX[k]j = INDEX_J = 3`.

**Typical**

- \( \text{MAX}_I > 1 \)
- \( \text{MAX}_J > 1 \)
- \( |\text{MATRIX}| > 3 \)
- \( \text{maxval}(\text{MATRIX}.i) > 1 \)
- \( \text{maxval}(\text{MATRIX}.j) > 1 \)
- \( \text{range}(\text{MATRIX}.v) > 1 \)

**Symmetry**

All occurrences of two distinct values in `MATRIX.v` or `VALUE` can be swapped; all occurrences of a value in `MATRIX.v` or `VALUE` can be renamed to any unused value.

**Reformulation**

The `ELEMENT_MATRIX(MAX_I, MAX_J, INDEX_I, INDEX_J, MATRIX, VALUE)` constraint can be expressed in term of `MAX_I ELEMENT(INDEX_J, LINE_i, VAR_i) (i \in [1, MAX_I])`, where `LINE_i` corresponds to the \( i \)-th line of the matrix `MATRIX` and of one `ELEMENT(INDEX_I, \{VAR_1, VAR_2, \ldots, VAR_{MAX_J}\}, VALUE)` constraint.

If we consider the `Example` slot we get the following `ELEMENT` constraints:

- `ELEMENT(3, \{4, 1, 7\}, 7)`,
- `ELEMENT(3, \{1, 0, 8\}, 8)`,
- `ELEMENT(3, \{3, 2, 1\}, 1)`,
- `ELEMENT(3, \{0, 0, 6\}, 6)`,
- `ELEMENT(1, \{7, 8, 1, 6\}, 7)`.

**Systems**

`NTH` in `Choco`, `ELEMENT` in `Gecode`.

**See also**

common keyword: `ELEM`, `ELEMENT (array constraint)`.

**Keywords**

characteristic of a constraint: automaton, automaton without counters, reified automaton constraint, derived collection.

constraint arguments: ternary constraint.

constraint network structure: centered cyclic(3) constraint network(1).

constraint type: data constraint.

filtering: arc-consistency.

modelling: array constraint, matrix.
**Derived Collection**

\[
\text{col} \left( \text{ITEM} - \text{collection}(\text{index}_i - \text{dvar}, \text{index}_j - \text{dvar}, \text{value} - \text{dvar}), \right. \\
\left. |\text{item}(\text{index}_i - \text{INDEX}_I, \text{index}_j - \text{INDEX}_J, \text{value} - \text{VALUE})| \right)
\]

**Arc input(s)**

ITEM MATRIX

**Arc generator**

\[\text{PRODUCT} \rightarrow \text{collection} (\text{item}, \text{matrix})\]

**Arc arity**

2

**Arc constraint(s)**

- \(\text{item.index}_i = \text{matrix.i}\)
- \(\text{item.index}_j = \text{matrix.j}\)
- \(\text{item.value} = \text{matrix.v}\)

**Graph property(ies)**

NARC = 1

**Graph model**

Similar to the ELEMENT constraint except that the arc constraint is updated according to the fact that we have a two-dimensional matrix.

Parts (A) and (B) of Figure 5.336 respectively show the initial and final graph associated with the Example slot. Since we use the NARC graph property, the unique arc of the final graph is stressed in bold.

![Graph](image)

**Signature**

Because of the first condition of the arc constraint the final graph cannot have more than one arc. Therefore we can rewrite NARC = 1 to \(\text{NARC} \geq 1\) and simplify NARC to \(\text{NARC}\).
Automaton

Figure 5.337 depicts the automaton associated with the ELEMENT_MATRIX constraint. Let $I_k$, $J_k$ and $V_k$ respectively be the $i$, the $j$ and the $v$ $k^{th}$ attributes of the MATRIX collection. To each sextuple $(INDEX, INDEX, VALUE, I_k, J_k, V_k)$ corresponds a 0-1 signature variable $S_k$ as well as the following signature constraint: $((INDEX = I_k) \land (INDEX = J_k) \land (VALUE = V_k)) \iff S_k$.

Figure 5.337: Automaton of the ELEMENT_MATRIX constraint

Figure 5.338: Hypergraph of the reformulation corresponding to the automaton of the ELEMENT_MATRIX constraint where $n$ and $m$ respectively stands for $\text{MAX}_I$ and $\text{MAX}_J$. 
5.145  ELEMENT_PRODUCT

**Origin**  
[311]

**Constraint**  
ELEMENT_PRODUCT(Y, TABLE, X, Z)

**Synonym**  
ELEMENT.

**Arguments**
- \( Y \) : dvar
- \( \text{TABLE} \) : collection(value−int)
- \( X \) : dvar
- \( Z \) : dvar

**Restrictions**
- \( Y \geq 1 \)
- \( Y \leq |\text{TABLE}| \)
- \( X \geq 0 \)
- \( Z \geq 0 \)
- \( \text{required}(|\text{TABLE}.\text{value}|) \)
- \( \text{TABLE}.\text{value} \geq 0 \)

**Purpose**  
\( Z \) is equal to the \( Y \text{th} \) item of \( \text{TABLE} \) multiplied by \( X \).

**Example**

\[
(3, (6, 9, 2, 9), 5, 10)
\]

The ELEMENT_PRODUCT constraint holds since its fourth argument \( Z = 10 \) is equal to the \( 3\text{rd} \) \((Y = 3)\) item of the collection \((6, 9, 2, 9)\) multiplied by \( X = 5 \).

**Typical**
- \( X > 0 \)
- \( Z > 0 \)
- \( |\text{TABLE}| > 1 \)
- \( \text{range}(|\text{TABLE}.\text{value}|) > 1 \)
- \( \text{TABLE}.\text{value} > 0 \)

**Arg. properties**
- **Functional dependency**: \( Z \) determined by \( Y, \text{TABLE} \) and \( X \).
- **Suffix-extensible wrt. \text{TABLE}**.

**Usage**  
The ELEMENT_PRODUCT constraint was originally used in configuration problems [311]. In this context, \( Z \) denotes the cost of buying \( X \) units of type \( Y \) at cost \( \text{TABLE}[Y].\text{value} \).

**Reformulation**

By introducing an extra variable \( \text{VAL} \), the ELEMENT_PRODUCT\((Y, \text{TABLE}, X, Z)\) constraint can be expressed in term of an ELEMENT\((Y, \text{TABLE}, \text{VAL})\) constraint and of a product constraint \( Z = \text{VAL} \cdot X \).
See also  

common keyword: ELEM, ELEMENT, ELEMENT_GREATEREQ, ELEMENT_LESSEQ (array constraint).

Keywords  

application area: configuration problem.

constraint arguments: pure functional dependency.

constraint type: data constraint.

modelling: array constraint, table, functional dependency, variable subscript.
Derived Collection

\[
\begin{aligned}
\text{col} & \left( \text{ITEM} - \text{collection}(y - \text{dvar}, x - \text{dvar}, z - \text{dvar}), \\
& \quad \text{item}(y - Y, x - X, z - Z) \right)
\end{aligned}
\]

Arc input(s) ITEM TABLE
Arc generator \( PRODUCT \rightarrow \text{collection(item, table)} \)
Arc arity 2
Arc constraint(s)

- item.y = table.key
- item.z = item.x * table.value

Graph property(ies) \( \text{NARC} = 1 \)

Graph model

We use the derived collection ITEM for putting together the \( Y \), the \( X \) and \( Z \) parameters of the ELEMENT_PRODUCT constraint. Within the arc constraint we use the implicit attribute \( \text{key} \) that associates to each item of a collection its position within the collection.

Parts (A) and (B) of Figure 5.339 respectively show the initial and final graph associated with the Example slot. Since we use the \( \text{NARC} \) graph property, the unique arc of the final graph is stressed in bold.

![Graph Model Diagram](image)

Figure 5.339: Initial and final graph of the ELEMENT_PRODUCT constraint

Signature

Because of the first condition of the arc constraint the final graph cannot have more than one arc. Therefore we can rewrite \( \text{NARC} = 1 \) to \( \text{NARC} \geq 1 \) and simplify \( \text{NARC} \) to \( \text{NARC} \).
5.146 ELEMENT_SPARSE

Origin: CHIP

Constraint: ELEMENT_SPARSE(ITEM, TABLE, DEFAULT)

Usual name: ELEMENT

Arguments:
- ITEM: collection(index−dvar, value−dvar)
- TABLE: collection(index−int, value−int)
- DEFAULT: int

Restrictions:
- required(ITEM, [index, value])
  ITEM.index ≥ 1
  |ITEM| = 1
  |TABLE| > 0
- required(TABLE, [index, value])
  TABLE.index ≥ 1
- distinct(TABLE, index)

Purpose: ITEM[1].value is equal to one of the entries of the table TABLE or to the default value DEFAULT if the entry ITEM[1].index does not exist in TABLE.

Example:

\[
\begin{pmatrix}
(index - 2 \text{ value - 5}), \\
  \text{index - 1 value - 6,} \\
  \text{index - 2 value - 5,} \\
  \text{index - 4 value - 2,} \\
  \text{index - 8 value - 9}
\end{pmatrix}
\]

The ELEMENT_SPARSE constraint holds since its first argument ITEM corresponds to the second item of the TABLE collection.

Typical:
- |TABLE| > 1
- range(TABLE.value) > 1

Symmetries:
- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEM.value, TABLE.value or DEFAULT can be swapped; all occurrences of a value in ITEM.value, TABLE.value or DEFAULT can be renamed to any unused value.

Usage:
A sometimes more compact form of the ELEMENT constraint: we are not obliged to specify explicitly the table entries that correspond to the specified default value. This can sometimes reduce drastically memory utilisation.
Remark

The original constraint of CHIP had an additional parameter SIZE giving the maximum value of ITEM.index.

Reformulation

Let I and V respectively denote ITEM[1].index and ITEM[1].value. The ELEMENT_SPARSE(ITEM, TABLE, DEFAULT) constraint can be expressed in term of a reified constraint of the form:

\[(I = \text{TABLE}[1].\text{index} \land V = \text{TABLE}[1].\text{value}) \lor \]
\[(I = \text{TABLE}[2].\text{index} \land V = \text{TABLE}[2].\text{value}) \lor \]
\[... \]
\[(I = \text{TABLE}[\text{TABLE}.\text{index}] \land V = \text{TABLE}[\text{TABLE}.\text{value}]) \lor \]
\[(I \neq \text{TABLE}[1].\text{index}) \land \]
\[(I \neq \text{TABLE}[2].\text{index}) \land \]
\[... \]
\[(I \neq \text{TABLE}[\text{TABLE}.\text{index}]) \land \]
\[(V = \text{DEFAULT})].\]

See also

common keyword:  ELEM, ELEMENT (array constraint), ELEMENTS_SPARSE (sparse table).

implies:  ELEMENTS_SPARSE.

system of constraints:  ELEMENTS_SPARSE.

Keywords

classification of a constraint:  automaton, automaton without counters, reified automaton constraint, derived collection.

constraint arguments:  binary constraint.

constraint network structure:  centered cyclic(2) constraint network(1).

constraint type:  data constraint.

filtering:  arc-consistency.

modelling:  array constraint, table, sparse table, sparse functional dependency, variable indexing.
Derived Collections

\[
\begin{align*}
col (\text{DEF} - \text{collection}(\text{index} \rightarrow \text{int}, \text{value} \rightarrow \text{int}), \\
\quad [\text{item}(\text{index} \rightarrow 0, \text{value} \rightarrow \text{DEFAULT}]) \\
\text{TABLE_DEF} - \text{collection}(\text{index} \rightarrow \text{dvar}, \text{value} \rightarrow \text{dvar}), \\
\quad [\text{item}(\text{index} \rightarrow \text{TABLE.index}, \text{value} \rightarrow \text{TABLE.value}), \\
\quad \text{item}(\text{index} \rightarrow \text{DEF.index}, \text{value} \rightarrow \text{DEF.value})])
\end{align*}
\]

Arc input(s) ITEM TABLE_DEF
Arc generator \( \text{PRODUCT} \rightarrow \text{collection}(\text{item}, \text{table_def}) \)
Arc arity 2
Arc constraint(s) 
- \text{item}.\text{value} = \text{table_def}.\text{value}
- \text{item}.\text{index} = \text{table_def}.\text{index} \lor \text{table_def}.\text{index} = 0

Graph property(ies) \( \text{NARC} \geq 1 \)

Graph model

The final graph has between one and two arc constraints: it has two arcs when the default value \text{DEFAULT} occurs also in the table \text{TABLE}; otherwise it has only one arc.

Parts (A) and (B) of Figure 5.340 respectively show the initial and final graph associated with the Example slot. Since we use the \text{NARC} graph property the arcs of the final graph are outline with thick lines.

Figure 5.340: Initial and final graph of the \text{ELEMENT_SPIRASE} constraint
Automaton

Figure 5.341 depicts the automaton associated with the ELEMENT\_SPARSE constraint. Let INDEX and VALUE respectively be the index and the value attributes of the unique item of the ITEM collection. Let INDEX\(_i\) and VALUE\(_i\) respectively be the index and the value attributes of the \(i^{th}\) item of the TABLE collection. To each quintuple \((\text{INDEX}, \text{VALUE}, \text{DEFAULT}, \text{INDEX} \_i, \text{VALUE} \_i)\) corresponds a signature variable \(S_i\) as well as the following signature constraint:

\[
\begin{align*}
\{ 
\text{INDEX} & \neq \text{INDEX} \_i \land \text{VALUE} \neq \text{DEFAULT} \} \Leftrightarrow S_i = 0 \\
\text{INDEX} = \text{INDEX} \_i \land \text{VALUE} = \text{VALUE} \_i \} \Leftrightarrow S_i = 1 \\
\text{INDEX} \neq \text{INDEX} \_i \land \text{VALUE} = \text{DEFAULT} \} \Leftrightarrow S_i = 2
\end{align*}
\]

Figure 5.341: Automaton of the ELEMENT\_SPARSE constraint
Figure 5.342: Hypergraph of the reformulation corresponding to the automaton of the ELEMENT_SPARSE constraint
ELEMENT_SPARSE 1227
5.147 ELEMENTN

Description

Origin
P. Flener

Constraint
ELEMENTN(INDEX, TABLE, ENTRIES)

Arguments

\[
\begin{align*}
\text{INDEX} & : \text{dvar} \\
\text{TABLE} & : \text{collection(value-int)} \\
\text{ENTRIES} & : \text{collection(entry-dvar)}
\end{align*}
\]

Restrictions

\[
\begin{align*}
\text{INDEX} & \geq 1 \\
\text{INDEX} & \leq |\text{TABLE}| - |\text{ENTRIES}| + 1 \\
|\text{TABLE}| & > 0 \\
|\text{ENTRIES}| & > 0 \\
|\text{TABLE}| & \geq |\text{ENTRIES}| \\
\text{required}(\text{TABLE, value}) & \\
\text{required}(\text{ENTRIES, entry}) & 
\end{align*}
\]

Purpose

\[
\forall i \in [1, |\text{ENTRIES}|] : \text{ENTRIES}[i].\text{entry} = \text{TABLE}[\text{INDEX} + i - 1].\text{value}
\]

Example

\[(3, (6, 9, 2, 9), (2, 9))\]

The ELEMENTN constraint holds since its third argument \(\text{ENTRIES} = (2, 9)\) is set to the subsequence starting at the third (i.e., \(\text{INDEX} = 3\)) item of the table \(\text{TABLE} = (6, 9, 2, 9)\).

Typical

\[
\begin{align*}
|\text{TABLE}| & > 1 \\
\text{range}(\text{TABLE.value}) & > 1 \\
|\text{ENTRIES}| & > 1
\end{align*}
\]

Symmetry

All occurrences of two distinct values in \(\text{TABLE.value}\) or \(\text{ENTRIES}.\text{entry}\) can be swapped; all occurrences of a value in \(\text{TABLE.value}\) or \(\text{ENTRIES}.\text{entry}\) can be renamed to any unused value.

Arg. properties

Suffix-extensible wrt. \(\text{TABLE}\).

Usage

The ELEMENTN constraint is useful for extracting of subsequence of fixed length from a given sequence.

Reformulation

Let \(I_1 = \text{INDEX}, I_2 = \text{INDEX} + 1, \ldots, I_{|\text{ENTRIES}|} = \text{INDEX} + |\text{ENTRIES}| - 1\). The \(\text{ELEMENTN}(\text{INDEX, TABLE, } (\text{entry} - E_1, \text{entry} - E_2, \ldots, \text{entry} - E_{|\text{ENTRIES}|}))\) constraint can be expressed in term of a conjunction of \(\text{ENTRIES}\) \(\text{ELEMENT}\) constraints of the form:

\[
\begin{align*}
\text{ELEMENT}(I_1, \text{TABLE}, E_1), \\
\text{ELEMENT}(I_2, \text{TABLE}, E_2), \\
\ldots \\
\text{ELEMENT}(\text{INDEX} + |\text{ENTRIES}| - 1, \text{TABLE}, E_{|\text{ENTRIES}|}).
\end{align*}
\]
See also

**common keyword**: ELEMENT (*data constraint*).

**Keywords**

**characteristic of a constraint**: automaton, automaton without counters, reified automaton constraint.

**constraint network structure**: Berge-acyclic constraint network.

**constraint type**: data constraint, sliding sequence constraint.

**filtering**: arc-consistency.

**modelling**: table.
Figure 5.343 depicts the automaton associated with the ELEMENT constraint of the Example slot. Let $I$ and $E_k$ respectively denote the INDEX argument and the entry attribute of the $k^{th}$ item of the ENTRIES collection. Figure 5.344 depicts the reformulation of the ELEMENT constraint.

![Automaton Diagram]

Figure 5.343: Automaton of the ELEMENT constraint given in the example

![Hypergraph Diagram]

Figure 5.344: Hypergraph of the reformulation corresponding to the automaton of the ELEMENT constraint
5.148  ELEMENTS

Origin
Derived from ELEMENT.

Constraint
ELEMENTS(ITEMS, TABLE)

Arguments
ITEMS : collection(index−dvar, value−dvar)
TABLE : collection(index−int, value−dvar)

Restrictions
required(ITEMS,[index, value])
ITEMS.index ≥ 1
ITEMS.index ≤ |TABLE|
required(TABLE,[index, value])
TABLE.index ≥ 1
TABLE.index ≤ |TABLE|
distinct(TABLE, index)

Purpose
All the items of ITEMS should be equal to one of the entries of the table TABLE.

Example
\[
\begin{pmatrix}
\langle index−4\ value−9, index−1\ value−6 \rangle, \\
\langle index−1\ value−6, \\
\langle index−2\ value−9, \\
\langle index−3\ value−2, \\
\langle index−4\ value−9
\end{pmatrix}
\]

The ELEMENTS constraint holds since each item of its first argument ITEMS corresponds to an item of the TABLE collection: the first item \(\langle index−4\ value−9 \rangle\) of ITEMS corresponds to the fourth item of TABLE, while the second item \(\langle index−1\ value−6 \rangle\) of ITEMS corresponds to the first item of TABLE.

Typical
\[
\begin{align*}
|ITEMS| & > 1 \\
\text{range}(ITEMS.index) & > 1 \\
|TABLE| & > 1 \\
\text{range}(TABLE.value) & > 1
\end{align*}
\]

Symmetries
- Items of ITEMS are permutable.
- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEMS.value or TABLE.value can be swapped; all occurrences of a value in ITEMS.value or TABLE.value can be renamed to any unused value.

Arg. properties
Functional dependency: ITEMS.value determined by ITEMS.index and TABLE.
Usage

Used for replacing several ELEMENT constraints sharing exactly the same table by a single constraint.

Reformulation

The ELEMENTS\(\langle index - I_1 \text{ value} - V_1, index - I_2 \text{ value} - V_2, \ldots, index - I_{|ITEMS|} \text{ value} - V_{|ITEMS|}, \text{TABLE} \rangle\) constraint can be expressed in term of a conjunction of \(|ITEMS|\) ELEM constraints of the form:

\[
\begin{align*}
\text{ELEM}(\langle index - I_1 \text{ value} - V_1 \rangle, \text{TABLE}), \\
\text{ELEM}(\langle index - I_2 \text{ value} - V_2 \rangle, \text{TABLE}), \\
\ldots \\
\text{ELEM}(\langle index - I_{|ITEMS|} \text{ value} - V_{|ITEMS|} \rangle, \text{TABLE}).
\end{align*}
\]

See also

implied by: ELEM, ELEMENTS_ALLDIFFERENT.
part of system of constraints: ELEM, ELEMENT.

Keywords

constraint arguments: pure functional dependency.
constraint type: data constraint, system of constraints.
filtering: arc-consistency.
modelling: table, shared table, functional dependency.

Cond. implications

ELEMENTS(ITEMS, TABLE)

- with distinct(ITEMS, index)
- and TABLE.value \(\geq 0\)
- implies BIN_PACKING_CAPA(TABLE, ITEMS).
Arc input(s) | ITEMS TABLE
---|---
Arc generator | $PRODUCT \rightarrow \text{collection}(\text{items,table})$
Arc arity | 2
Arc constraint(s) | • items.index = table.index  
  • items.value = table.value
Graph property(ies) | $\text{NARC} = |\text{ITEMS}|$

**Graph model**

Parts (A) and (B) of Figure 5.345 respectively show the initial and final graph associated with the **Example** slot. Since we use the $\text{NARC}$ graph property, the arcs of the final graph are stressed in bold.

![Graph model](image)

**Signature**

Since all the index attributes of TABLE collection are distinct and because of the first condition $\text{items.index} = \text{table.index}$ of the arc constraint, a source vertex of the final graph can have at most one successor. Therefore $|\text{ITEMS}|$ is the maximum number of arcs of the final graph and we can rewrite $\text{NARC} = |\text{ITEMS}|$ to $\text{NARC} \geq |\text{ITEMS}|$. So we can simplify $\text{NARC}$ to $\text{NARC}$. 

---

**Figure 5.345:** Initial and final graph of the ELEMENTS constraint
5.149 ELEMENTS_ALLDIFFERENT

Origin
Derived from ELEMENTS and ALLDIFFERENT.

Constraint
ELEMENTS_ALLDIFFERENT(ITEMS, TABLE)

Synonyms
ELEMENTS_ALLDIFF, ELEMENTS_ALLDISTINCT, PERMUTATION.

Arguments
ITEMS : collection(index−dvar, value−dvar)
TABLE : collection(index−int, value−dvar)

Restrictions
required(ITEMS, [index, value])
ITEMS.index ≥ 1
ITEMS.index ≤ |TABLE|
|ITEMS| = |TABLE|
required(TABLE, [index, value])
TABLE.index ≥ 1
TABLE.index ≤ |TABLE|
distinct(TABLE, index)

Purpose
All the items of the ITEMS collection should be equal to one of the entries of the table TABLE and all the variables ITEMS:index should take distinct values.

Example
\[
\begin{pmatrix}
\text{index} - 2 & \text{value} - 9, \\
\text{index} - 1 & \text{value} - 6, \\
\text{index} - 4 & \text{value} - 9, \\
\text{index} - 3 & \text{value} - 2
\end{pmatrix}
\]

The ELEMENTS_ALLDIFFERENT constraint holds since, as depicted by Figure 5.346, there is a one to one correspondence between the items of the ITEMS collection and the items of the TABLE collection.

Figure 5.346: Illustration of the one to one correspondence between the items of ITEMS and the items of TABLE
Typical

\[ |\text{ITEMS}| > 1 \]
\[ \text{range}(\text{ITEMS}\text{.value}) > 1 \]
\[ |\text{TABLE}| > 1 \]
\[ \text{range}(\text{TABLE}\text{.value}) > 1 \]

Symmetries

- Arguments are permutable w.r.t. permutation (ITEMS, TABLE).
- Items of ITEMS are permutable.
- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEMS\text{.value} or TABLE\text{.value} can be swapped; all occurrences of a value in ITEMS\text{.value} or TABLE\text{.value} can be renamed to any unused value.

Arg. properties

Functional dependency: ITEMS\text{.value} determined by ITEMS\text{.index} and TABLE.

Usage

Used for replacing by a single ELEMENTS\_ALLDIFFERENT constraint an ALLDIFFERENT and a set of ELEMENT constraints having the following structure:

- The union of the index variables of the ELEMENT constraints is equal to the set of variables of the ALLDIFFERENT constraint.
- All the ELEMENT constraints share exactly the same table.

For instance, the constraint given in the Example slot is equivalent to the conjunction of the following set of constraints:

\[
\text{ALLDIFFERENT}((\text{var} - 2, \text{var} - 1, \text{var} - 4, \text{var} - 3))
\]

\[
\text{ELEMENT} \begin{cases} \langle \text{index} - 2, \text{value} - 9 \rangle, \\
\text{index} - 1, \text{value} - 6, \\
\text{index} - 2, \text{value} - 9, \\
\text{index} - 3, \text{value} - 2, \\
\text{index} - 4, \text{value} - 9 \end{cases}
\]

\[
\text{ELEMENT} \begin{cases} \langle \text{index} - 1, \text{value} - 6 \rangle, \\
\text{index} - 1, \text{value} - 6, \\
\text{index} - 2, \text{value} - 9, \\
\text{index} - 3, \text{value} - 2, \\
\text{index} - 4, \text{value} - 9 \end{cases}
\]

\[
\text{ELEMENT} \begin{cases} \langle \text{index} - 3, \text{value} - 2 \rangle, \\
\text{index} - 1, \text{value} - 6, \\
\text{index} - 2, \text{value} - 9, \\
\text{index} - 3, \text{value} - 2, \\
\text{index} - 4, \text{value} - 9 \end{cases}
\]

\[
\text{ELEMENT} \begin{cases} \langle \text{index} - 4, \text{value} - 9 \rangle, \\
\text{index} - 1, \text{value} - 6, \\
\text{index} - 2, \text{value} - 9, \\
\text{index} - 3, \text{value} - 2, \\
\text{index} - 4, \text{value} - 9 \end{cases}
\]
As a practical example of utilisation of the ELEMENTS_ALLDIFFERENT constraint we show how to model the link between a permutation consisting of a single cycle and its expanded form. For instance, to the permutation 3, 6, 5, 2, 4, 1 corresponds the sequence 3 5 4 2 6 1. Let us note \( S_1, S_2, S_3, S_4, S_5, S_6 \) the permutation and \( V_1, V_2, V_3, V_4, V_5, V_6 \) its expanded form (see Figure 5.347).

The constraint:

\[
\begin{pmatrix}
\text{index} - V_1 & \text{value} - V_2,
\text{index} - V_2 & \text{value} - V_3,
\text{index} - V_3 & \text{value} - V_4,
\text{index} - V_4 & \text{value} - V_5,
\text{index} - V_5 & \text{value} - V_6,
\text{index} - 1 & \text{value} - S_1,
\text{index} - 2 & \text{value} - S_2,
\text{index} - 3 & \text{value} - S_3,
\text{index} - 4 & \text{value} - S_4,
\text{index} - 5 & \text{value} - S_5,
\text{index} - 6 & \text{value} - S_6
\end{pmatrix}
\]

models the fact that \( S_1, S_2, S_3, S_4, S_5, S_6 \) corresponds to a permutation with a single cycle. It also expresses the link between the variables \( S_1, S_2, S_3, S_4, S_5, S_6 \) and \( V_1, V_2, V_3, V_4, V_5, V_6 \).

Figure 5.347: Two representations of a permutation containing a single cycle

**Reformulation**

The \( \text{ELEMENTS\_ALLDIFFERENT}((\text{index} - I_1 \text{ value} - V_1, \text{index} - I_2 \text{ value} - V_2, \ldots, \text{index} - I_{\text{ITEMS}} \text{ value} - V_{\text{ITEMS}}), \text{TABLE}) \) constraint can be expressed in term of a conjunction of \( \text{ITEMS} \) \( \text{ELEM} \) constraints and of one \( \text{ALLDIFFERENT} \) constraint of the form:

\[
\begin{align*}
\text{ELEM}((\text{index} - I_1 \text{ value} - V_1), \text{TABLE}), \\
\text{ELEM}((\text{index} - I_2 \text{ value} - V_2), \text{TABLE}), \\
\ldots \\
\text{ELEM}((\text{index} - I_{\text{ITEMS}} \text{ value} - V_{\text{ITEMS}}), \text{TABLE}), \\
\text{ALLDIFFERENT}((I_1, I_2, \ldots, I_{\text{ITEMS}})).
\end{align*}
\]
See also: implies: ELEMENTS, INDEXED_SUM.
used in reformulation: ALLDIFFERENT, ELEM, ELEMENT.

Keywords: characteristic of a constraint: disequality.
combinatorial object: permutation.
constraint type: data constraint.
modelling: array constraint, table, functional dependency.

Cond. implications: ELEMENTS_ALLDIFFERENT(ITEMS, TABLE)
    with TABLE.value ≥ 0
    implies BIN_PACKING_CAPA(TABLE, ITEMS).
Arc input(s)  ITEMS TABLE
Arc generator  \( \text{PRODUCT} \mapsto \text{collection}(\text{items}, \text{table}) \)
Arc arity  2
Arc constraint(s)  
  • \( \text{items.index} = \text{table.index} \)
  • \( \text{items.value} = \text{table.value} \)
Graph property(ies)  \( \text{NVERTEX} = |\text{ITEMS}| + |\text{TABLE}| \)

Graph model  
The fact that all variables \( \text{ITEMS}.\text{index} \) are pairwise different is derived from the conjunctions of the following facts:

  • From the graph property \( \text{NVERTEX} = |\text{ITEMS}| + |\text{TABLE}| \) it follows that all vertices of the initial graph belong also to the final graph,

  • A vertex \( v \) belongs to the final graph if there is at least one constraint involving \( v \) that holds,

  • From the first condition \( \text{items.index} = \text{table.index} \) of the arc constraint, and from the restriction \( \text{distinct}(\text{TABLE}.\text{index}) \) it follows: for all vertices \( v \) generated from the collection \( \text{ITEMS} \) at most one constraint involving \( v \) holds.

Parts (A) and (B) of Figure 5.348 respectively show the initial and final graph associated with the Example slot. Since we use the \( \text{NVERTEX} \) graph property, the vertices of the final graph are stressed in bold.

![Graph model](image)

**Figure 5.348**: Initial and final graph of the \( \text{ELEMENTS\_ALLDIFFERENT} \) constraint

Signature  
Since the final graph cannot have more than \( |\text{ITEMS}| + |\text{TABLE}| \) vertices one can simplify \( \text{NVERTEX} \) to \( \text{NVERTEX} \).
ELEMENTS_ALLDIFFERENT

1241
5.150  ELEMENTS_SPARSE

Origin

Derived from ELEMENTS_SPARSE.

Constraint

ELEMENTS_SPARSE(ITEMS, TABLE, DEFAULT)

Arguments

ITEMS : collection(index−dvar, value−dvar)
TABLE : collection(index−int, value−int)
DEFAULT : int

Restrictions

required(ITEMS, [index, value])
ITEMS.index ≥ 1
required(TABLE, [index, value])
TABLE.index ≥ 1
distinct(TABLE, index)

Purpose

All the items of ITEMS should be equal to one of the entries of the table TABLE or to the default value DEFAULT if the entry ITEMS.index does not occurs among the values of the index attribute of the TABLE collection.

Example

\[
\begin{pmatrix}
\text{index - 8} & \text{value - 9}, \\
\text{index - 3} & \text{value - 5}, \\
\text{index - 2} & \text{value - 5} \\
\text{index - 1} & \text{value - 6}, \\
\text{index - 2} & \text{value - 5}, \\
\text{index - 4} & \text{value - 2}, \\
\text{index - 8} & \text{value - 9}
\end{pmatrix}
\]

The ELEMENTS_SPARSE constraint holds since:

- The first and third items (items \{index - 8 value - 9\} and \{index - 2 value - 5\}) of its ITEMS collection respectively correspond to the fourth and second item of its TABLE collection.
- The index attribute of the second item of its ITEMS collection (i.e., value 3) does not correspond to any index of the TABLE collection. Therefore the value attribute of the second item of the ITEMS collection is set the the default value 5 given by the last argument of the ELEMENTS_SPARSE constraint.

Typical

|ITEMS| > 1
|range(ITEMS.value) > 1
|TABLE| > 1
|range(TABLE.value) > 1
**Elements_sparse**

### Symmetries
- Items of ITEMS are permutable.
- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEMS.value, TABLE.value or DEFAULT can be swapped; all occurrences of a value in ITEMS.value, TABLE.value or DEFAULT can be renamed to any unused value.

### Usage
Used for replacing several ELEMENT constraints sharing exactly the same sparse table by a single constraint.

### Reformulation
Let $I_k$ and $V_k$ respectively denote ITEMS[$k$.index and ITEMS[$k$.value ($k \in [1, |ITEMS|]$). The ELEMENTS_SPARSE(ITEMS, TABLE, DEFAULT) constraint can be expressed in term of $|ITEMS|$ reified constraints of the form:

\[
\begin{align*}
(I_k = \text{TABLE}[1].index \land V_k = \text{TABLE}[1].value) \lor \\
(I_k = \text{TABLE}[2].index \land V_k = \text{TABLE}[2].value) \lor \\
& \cdots \\
(I_k = \text{TABLE}[|TABLE|].index \land V_k = \text{TABLE}[|TABLE|].value) \lor \\
((I_k \neq \text{TABLE}[1].index) \land \\
(I_k \neq \text{TABLE}[2].index) \land \\
& \cdots \\
(V_k = \text{DEFAULT})).
\end{align*}
\]

### See also
- **Common keyword**: ELEM, ELEMENT (data constraint), ELEMENT_SPARSE (sparse table).
- **Implied by**: ELEMENT_SPARSE.
- **Part of system of constraints**: ELEMENT_SPARSE.

### Keywords
- **Characteristic of a constraint**: derived collection.
- **Constraint type**: data constraint, system of constraints.
- **Filtering**: arc-consistency.
- **Modelling**: table, shared table, sparse table, sparse functional dependency.
Derived Collections

\[
\begin{align*}
\text{col} &\text{(DEF}\text{-collection(index-int, value-int)}, \text{item(index - 0, value - DEFAULT))} \\
\text{col} &\text{(TABLE_DEF}\text{-collection(index-dvar, value-dvar),} \\
&\text{item(index - TABLE.index, value - TABLE.value),} \\
&\text{item(index - DEF.index, value - DEF.value))}
\end{align*}
\]

Arc input(s)

ITEMS TABLE_DEF

Arc generator

\[PRODUCT\rightarrow\text{collection(items, table_def)}\]

Arc arity

2

Arc constraint(s)

- items.value = table_def.value
- items.index = table_def.index ∨ table_def.index = 0

Graph property(ies)

\[\text{NSOURCE} = |\text{ITEMS}|\]

Graph model

An item of the ITEMS collection may have up to two successors (see, for example, the third item of the ITEMS collection of the Example slot). Therefore we use the graph property \(\text{NSOURCE} = |\text{ITEMS}|\) for enforcing the fact that each item of the ITEMS collection has at least one successor.

Parts (A) and (B) of Figure 5.349 respectively show the initial and final graph associated with the Example slot. Since we use the \(\text{NSOURCE}\) graph property, the vertices of the final graph are drawn with a double circle.

![Graph model](image)

Figure 5.349: Initial and final graph of the ELEMENTS_SPARSE constraint

Signature

On the one hand note that ITEMS is equal to the number of sources of the initial graph. On the other hand note that, in the initial graph, all the vertices that are not sources correspond to sinks. Since isolated vertices are eliminated from the final graph the sinks of the initial graph cannot become sources of the final graph. Therefore the maximum number of sources of the final graph is equal to ITEMS. We can rewrite \(\text{NSOURCE} = |\text{ITEMS}|\) to \(\text{NSOURCE} ≥ |\text{ITEMS}|\) and simplify \(\text{NSOURCE}\) to \(\text{NSOURCE}\).
### 5.151 EQ

<table>
<thead>
<tr>
<th>DESCRIPTION</th>
<th>LINKS</th>
</tr>
</thead>
</table>

**Origin**
Arithmetic.

**Constraint**
EQ(VAR1, VAR2)

**Synonym**
XEQY.

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>VAR1</td>
<td>dvar</td>
</tr>
<tr>
<td>VAR2</td>
<td>dvar</td>
</tr>
</tbody>
</table>

**Restriction**

**Purpose**
Enforce the fact that two variables are equal.

**Example**

\( (8, 8) \)

The EQ constraint holds since 8 is equal to 8.

**Symmetries**
- Arguments are permutable w.r.t. permutation (VAR1, VAR2).
- All occurrences of a value in VAR1 or VAR2 can be renamed to any unused value.

**Arg. properties**
- Functional dependency: VAR2 determined by VAR1.
- Functional dependency: VAR1 determined by VAR2.

**Systems**

<p>| | |</p>
<table>

  EQ_CST (constant added), EQ_SET (variable replaced by set variable).
- implies: ABS_VALUE, GEQ, LEQ, SAME_SIGN, ZERO_NOT_ZERO.
- negation: NEQ.

**Keywords**

- constraint arguments: binary constraint, pure functional dependency.
- constraint type: predefined constraint, arithmetic constraint.
- filtering: arc-consistency.
5.152  EQ\_CST

**Description**

- **Origin:** Arithmetic.
- **Constraint:** \(\text{EQ\_CST}(\text{VAR1}, \text{VAR2}, \text{CST2})\)
- **Arguments:**
  - \(\text{VAR1}: \text{dvar}\)
  - \(\text{VAR2}: \text{dvar}\)
  - \(\text{CST2}: \text{int}\)
- **Purpose:** Enforce the fact that the first variable is equal to the sum of the second variable and the constant.
- **Example:** \((8, 2, 6)\)
  - The EQ\_CST constraint holds since 8 is equal to 2 + 6.
- **Typical:** \(\text{CST2} \neq 0\)
- **Symmetries:**
  - Arguments are permutable w.r.t. permutation (VAR1) (VAR2, CST2).
  - One and the same constant can be added to \(\text{VAR1}\) and \(\text{VAR2}\).
  - One and the same constant can be added to \(\text{VAR1}\) and \(\text{CST2}\).
- **Arg. properties:**
  - Functional dependency: \(\text{VAR1} \text{ determined by } \text{VAR2} \text{ and } \text{CST2}\).
  - Functional dependency: \(\text{VAR2} \text{ determined by } \text{VAR1} \text{ and } \text{CST2}\).
  - Functional dependency: \(\text{CST2} \text{ determined by } \text{VAR1} \text{ and } \text{VAR2}\).
- **See also:**
  - implies: GEQ\_CST, LEQ\_CST.
  - negation: NEQ\_CST.
  - specialisation: EQ(\text{constant set to 0}).
- **Keywords:**
  - constraint arguments: binary constraint, pure functional dependency.
  - constraint type: predefined constraint, arithmetic constraint.
  - filtering: arc-consistency.
5.153  EQ_SET

Description

Origin
Used for defining ALLDIFFERENT_BETWEEN_SETS.

Constraint
EQ_SET(SET1, SET2)

Arguments

<table>
<thead>
<tr>
<th>SET1</th>
<th>: svar</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET2</td>
<td>: svar</td>
</tr>
</tbody>
</table>

Purpose
Constraint the set SET1 to be equal to the set SET2.

Example

\[\{(3,5), (3,5)\}\]

Symmetries

- Arguments are permutable w.r.t. permutation (SET1, SET2).
- All occurrences of a value in SET1 or SET2 can be renamed to any unused value.

Systems

EQ in Choco, REL in Gecode.

Used in
ALLDIFFERENT_BETWEEN_SETS.

See also
specialisation: EQ(set variable replaced by variable).

Keywords
characteristic of a constraint: equality.
constraint arguments: binary constraint, constraint involving set variables.
constraint type: predefined constraint.
### Description

**Origin**
Geometry, derived from [349]

**Constraint**
\[
\text{EQUAL\_SBOXES}(K, \text{DIMS}, \text{OBJECTS}, \text{SBOXES})
\]

**Synonym**
\[
\text{EQUAL}.
\]

### Types

<table>
<thead>
<tr>
<th>Collection Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARIABLES</td>
<td>(\text{collection}(v \text{- dvar}))</td>
</tr>
<tr>
<td>INTEGERS</td>
<td>(\text{collection}(v \text{- int}))</td>
</tr>
<tr>
<td>POSITIVES</td>
<td>(\text{collection}(v \text{- int}))</td>
</tr>
</tbody>
</table>

### Arguments

- **K** : \(\text{int}\)
- **DIMS** : \(\text{sint}\)
- **OBJECTS** : \(\text{collection}(oid \text{- int}, sid \text{- dvar}, x \text{- VARIABLES})\)
- **SBOXES** : \(\text{collection}(sid \text{- int}, t \text{- INTEGERS}, l \text{- POSITIVES})\)

### Restrictions

- \(|\text{VARIABLES}| \geq 1\)
- \(|\text{INTEGERS}| \geq 1\)
- \(|\text{POSITIVES}| \geq 1\)
- \(\text{required(VARIABLES, v)}\)
- \(\text{required(INTEGERS, v)}\)
- \(\text{required(POSITIVES, v)}\)
- \(\text{POSITIVES}.v > 0\)
- \(K > 0\)
- \(\text{DIMS} \geq 0\)
- \(\text{DIMS} < K\)
- \(\text{increasing\_seq(Object, oid)}\)
- \(\text{required(Object, [oid, sid, x])}\)
- \(\text{OBJECTS}.oid \geq 1\)
- \(\text{OBJECTS}.oid \leq |\text{OBJECTS}|\)
- \(\text{OBJECTS}.sid \geq 1\)
- \(\text{OBJECTS}.sid \leq |\text{SBOXES}|\)
- \(\text{|SBOXES|} \geq 1\)
- \(\text{required(SBOXES, [sid, t, l])}\)
- \(\text{SBOXES}.sid \geq 1\)
- \(\text{SBOXES}.sid \leq |\text{SBOXES}|\)
- \(\text{do\_not\_overlap(SBOXES)}\)
Holds if, for each pair of objects \((O_i, O_j), i \neq j\), \(O_i\) and \(O_j\) coincide exactly with respect to a set of dimensions depicted by \(\text{DIMS}\). \(O_i\) and \(O_j\) are objects that take a shape among a set of shapes. Each shape is defined as a finite set of shifted boxes, where each shifted box is described by a box in a \(K\)-dimensional space at a given offset (from the origin of the shape) with given sizes. More precisely, a shifted box is an entity defined by its shape id \(\text{sid}\), shift offset \(t\), and sizes \(l\). Then, a shape is defined as the union of shifted boxes sharing the same shape id. An object is an entity defined by its unique object identifier \(\text{oid}\), shape id \(\text{sid}\) and origin \(x\).

Two objects \(O_i\) and object \(O_j\) are equal with respect to a set of dimensions depicted by \(\text{DIMS}\) if and only if, for all shifted box \(s_i\) associated with \(O_i\) there exists a shifted box \(s_j\) such that, for all dimensions \(d \in \text{DIMS}\), (1) the origins of \(s_i\) and \(s_j\) coincide and, (2) the ends of \(s_i\) and \(s_j\) also coincide.

Figure 5.350 shows the objects of the example. Since these objects coincide exactly the \text{EQUAL\_SBOXES} constraint holds.

Typical

\[ |\text{OBJECTS}| > 1 \]

Symmetries

- Items of \text{OBJECTS} are \text{permutable}.
- Items of \text{SBOXES} are \text{permutable}.
- Items of \text{OBJECTS}.x, \text{SBOXES}.t and \text{SBOXES}.l are \text{permutable} (same permutation used).

Arg. properties

Suffix-contractible wrt. \text{OBJECTS}.

Remark

One of the eight relations of the \text{Region Connection Calculus} \cite{349}. The constraint \text{EQUAL\_SBOXES} is a restriction of the original relation since it requires to have exactly the same partition between the different objects.

if \( \text{CTR} = \text{LONGEST}_\text{CHANGE} \):
    \( \text{LONGEST}_\text{CHANGE}(C_1, \langle \text{VAR}_1, \ldots, \text{VAR}_{\text{INDEX}_1} \rangle, \neq) \)
    \( \text{LONGEST}_\text{CHANGE}(C_2, \langle \text{VAR}_{\text{INDEX}_2}, \ldots, \text{VAR}_{|\text{VARIABLES}|} \rangle, \neq) \)
if \( \text{CTR} = \text{SUM}_\text{CTR} \):
    \( \text{SUM}_\text{CTR}(\langle \text{VAR}_1, \ldots, \text{VAR}_{\text{INDEX}_1} \rangle, =, C_1) \)
    \( \text{SUM}_\text{CTR}(\langle \text{VAR}_{\text{INDEX}_2}, \ldots, \text{VAR}_{|\text{VARIABLES}|} \rangle, =, C_2) \)
else:
    \( \text{CTR}(C_1, \langle \text{VAR}_1, \ldots, \text{VAR}_{\text{INDEX}_1} \rangle) \)
    \( \text{CTR}(C_2, \langle \text{VAR}_{\text{INDEX}_2}, \ldots, \text{VAR}_{|\text{VARIABLES}|} \rangle) \)
```

\[ |\text{COEF}_1 \cdot C_1 - \text{COEF}_2 \cdot C_2| \leq \text{TOLERANCE} \]

**Example**

\[
\begin{align*}
(4, 4, 3, 6, 2), & 2, 4, 2, 1, 1, 0, \text{SUM}_\text{CTR} \\
(-2, 5, -2, 6, -1, 0, -3, 5, -7, 6, -1, 7, 0), & 5, 5, 0, 1, 1, 0, \text{SUM}_\text{CTR} \\
(-2, 5, -2, 6, -1, 0, -3, 5, -7, 6, -1, 7, 0), & 11, 11, 0, 1, 1, 0, \text{SUM}_\text{CTR} \\
(0, 3, 2, 6, 2, 2, 5, 8, 7, 6, 7, 3), & 5, 7, 2, 1, 1, 0, \text{PEAK} \\
(0, 5, 3, 8, 2, 2, 5, 8, 7, 2, 7, 3), & 7, 7, 0, 1, 1, 0, \text{CHANGE} \\
\end{align*}
\]
The first example, \( \text{EQUILIBRIUM}(\langle 4_1, 4_2, 3_3, 6_4, 2_5 \rangle, 2, 4, 2, 1, 1, 0, \text{SUM}_\text{CTR} \) holds since:

- \( \text{INDEX1} = 2 \geq 1 \)
- \( \text{INDEX2} = 4 \geq 1 \)
- \( \text{Epsilon} = 2 \geq 0 \)
- \( \text{INDEX1} = 2 \leq |\text{VARIABLES}| = 5 \)
- \( \text{INDEX2} = 4 \leq |\text{VARIABLES}| = 5 \)
- \( \text{Epsilon} = 2 \leq 2 \)
- \( \text{INDEX1} = 2 \leq \text{INDEX2} = 4 \)
- \( C_1 = 4_1 + 4_2 = 8 \)
- \( \text{INDEX2} - \text{INDEX1} = \text{Epsilon} = 2 \)
- \( C_2 = 6_4 + 2_5 = 8 \)
- \( |1 \cdot 8 - 1 \cdot 8| \leq \text{Tolerance} = 0 \)

![Figure 5.351: Illustration of the first example of the Example slot](image)

The second example, \( \text{EQUILIBRIUM}(\langle -2_1, 5_2, -2_3, 6_4, -1_5, 0_6, -3_7, 5_8, -7_9, 6_10, -1_{11}, 7_12, 0_{13} \rangle, 5, 5, 0, 1, 1, 0, \text{SUM}_\text{CTR} \) holds since:

- \( \text{INDEX1} = 5 \geq 1 \)
- \( \text{INDEX2} = 5 \geq 1 \)
- \( \text{Epsilon} = 0 \geq 0 \)
- \( \text{INDEX1} = 5 \leq |\text{VARIABLES}| = 13 \)
- \( \text{INDEX2} = 5 \leq |\text{VARIABLES}| = 13 \)
- \( \text{Epsilon} = 0 \leq 2 \)
- \( \text{Tolerance} = 0 \leq 0 \)
- \( C_1 = -2_1 + 5_2 - 2_3 + 6_4 - 1_5 = 6 \)
- \( \text{INDEX2} - \text{INDEX1} = \text{Epsilon} = 0 \)
- \( C_2 = -1_5 + 0_6 - 3_7 + 5_8 - 7_9 + 6_10 - 1_{11} + 7_12 + 0_{13} = 6 \)
- \( |1 \cdot 6 - 1 \cdot 6| \leq \text{Tolerance} = 0 \)

![Figure 5.352: Illustration of the second and third examples of the Example slot](image)

The third example, \( \text{EQUILIBRIUM}(\langle -2_1, 5_2, -2_3, 6_4, -1_5, 0_6, -3_7, 5_8, -7_9, 6_10, -1_{11}, 7_12, 0_{13} \rangle, 11, 11, 0, 1, 1, 0, \text{SUM}_\text{CTR} \) holds since:

- \( \text{INDEX1} = 11 \geq 1 \)
- \( \text{INDEX2} = 11 \geq 1 \)
- \( \text{Epsilon} = 0 \geq 0 \)
- \( \text{INDEX1} = 11 \leq \text{INDEX2} = 11 \)
- \( C_1 = -2_1 + 5_2 - 2_3 + 6_4 - 1_5 + 0_6 - 3_7 + 5_8 - 7_9 + 6_10 - 1_{11} = 6 \)

The fourth example, EQUILIBRIUM((01, 32, 23, 64, 25, 26, 57, 88, 79, 610, 711, 312), 5, 7, 2, 1, 1, 0, PEAK), holds since:

- INDEX1 = 5 ≥ 1,
- INDEX2 = 7 ≥ 1,
- EPSILON = 2 ≥ 0,
- INDEX1 = 5 ≤ INDEX2 = 7,
- the sequence 01 32 23 64 25 contains 2 peaks,
- INDEX2 − INDEX1 = EPSILON = 2,
- |1 · 2 − 1 · 2| ≤ TOLERANCE = 0

|1 · 2 − 1 · 2| ≤ TOLERANCE = 0

Figure 5.353: Illustration of the fourth example of the Example slot

The fifth example, EQUILIBRIUM((01, 52, 33, 84, 25, 26, 57, 58, 89, 710, 211, 712, 313), 7, 7, 0, 1, 1, 0, CHANGE), holds since:

- INDEX1 = 7 ≥ 1,
- INDEX2 = 7 ≥ 1,
- EPSILON = 0 ≥ 0,
- INDEX1 = 7 ≤ INDEX2 = 7,
- the sequence 01, 52, 33, 84, 25 contains 5 changes,
- INDEX2 − INDEX1 = EPSILON = 0,
- |1 · 5 − 1 · 5| ≤ TOLERANCE = 0.
|1 · 5 − 1 · 5| ≤ TOLERANCE = 0

| changes |
| 01 ≠ 52 ≠ 33 ≠ 84 ≠ 25 ≠ 26 ≠ 57 ≠ 58 ≠ 89 ≠ 710 ≠ 211 ≠ 712 ≠ 313 |
| 00 11 22 33 44 55 66 77 88 99 10 |
| # of changes on prefixes |
| # of changes on suffixes |

VARIABLES
EPSILON = 0

Figure 5.354: Illustration of the fifth example of the Example slot

Typical
| VARIABLES | > 2 |
| INDEX1 | > 1 |
| INDEX1 < | VARIABLES |
| INDEX2 | > 1 |
| INDEX2 < | VARIABLES |
| COEF1 | = 1 |
| COEF2 | = 1 |
| EPSILON | = 1 |
| TOLERANCE | = 0 |

See also root concept: BALANCE.

Keywords characteristic of a constraint: automaton with counters.
constraint type: predefined constraint.
5.156 EQUIVALENT

### Origin
Logic

### Constraint
EQUIVALENT(VAR, VARIABLES)

### Synonym
EQ.

### Arguments
- **VAR**: dvar
- **VARIABLES**: collection(var−dvar)

### Restrictions
- VAR ≥ 0
- VAR ≤ 1
- |VARIABLES| = 2
- required(VARIABLES, var)
- VARIABLES.var ≥ 0
- VARIABLES.var ≤ 1

### Purpose
Let VARIABLES be a collection of 0-1 variables VAR₁, VAR₂. Enforce VAR = (VAR₁ ⇔ VAR₂).

### Example
- (1, (0, 0))
- (0, (0, 1))
- (0, (1, 0))
- (1, (1, 1))

### Symmetries
- Items of VARIABLES are permutable.
- All occurrences of 0 in VAR and in VARIABLES.var can be set to 1.

### Arg. properties
Functional dependency: VAR determined by VARIABLES.

### Counting

Figure 5.356: Hypergraph of the reformulation corresponding to the automaton of the EQUIVALENT constraint
### 5.157 EXACTLY

#### DESCRIPTION

**Origin**
Derived from `ATLEAST` and `ATMOST`.

**Constraint**
\[\text{EXACTLY}(N, \text{VARIABLES}, \text{VALUE})\]

**Synonym**
`COUNT`.

**Arguments**
- \(N\) : int
- \(\text{VARIABLES}\) : collection(var–dvar)
- \(\text{VALUE}\) : int

**Restrictions**
- \(N \geq 0\)
- \(N \leq |\text{VARIABLES}|\)
- \(\text{required}(\text{VARIABLES}, \text{var})\)

**Purpose**
Exactly \(N\) variables of the \(\text{VARIABLES}\) collection are assigned value \(\text{VALUE}\).

**Example**
\[(2, (4, 2, 4, 5), 4)\]

The EXACTLY constraint holds since exactly \(N = 2\) variables of the \(\text{VARIABLES} = (4, 2, 4, 5)\) collection are assigned value \(\text{VALUE} = 4\).

**Typical**
- \(N > 0\)
- \(N < |\text{VARIABLES}|\)
- \(|\text{VARIABLES}| > 1\)

**Symmetries**
- Items of \(\text{VARIABLES}\) are permutable.
- An occurrence of a value of \(\text{VARIABLES}.\text{var}\) that is different from \(\text{VALUE}\) can be replaced by any other value that is also different from \(\text{VALUE}\).

**Arg. properties**
- Functional dependency: \(N\) determined by \(\text{VARIABLES}\) and \(\text{VALUE}\).
- Aggregate: \(N(+)\), \(\text{VARIABLES}(\text{union})\), \(\text{VALUE}(\text{id})\).

**Systems**
- OCCURRENCE in Choco, COUNT in Gecode, EXACTLY in Gecode, COUNT in JaCoP, EXACTLY in MiniZinc, COUNT in SICStus.

**See also**
- generalisation: AMONG (constant replaced by variable and value replaced by list of values).
- implies: ATLEAST (\(= N\) replaced by \(\geq N\)), ATMOST (\(= N\) replaced by \(\leq N\)).
Keywords

characteristic of a constraint: automaton, automaton with counters.
constraint arguments: reverse of a constraint, pure functional dependency.
constraint network structure: alpha-acyclic constraint network(2).
constraint type: value constraint, counting constraint.
filtering: glue matrix, arc-consistency.
modelling: functional dependency.
Arc input(s)  VARIABLES
Arc generator  \( SELF \rightarrow \text{collection}(\text{variables}) \)
Arc arity  1
Arc constraint(s)  \( \text{variables}.\text{var} = \text{VALUE} \)
Graph property(ies)  \( \text{NARC} = N \)

Graph model
Since each arc constraint involves only one vertex (VALUE is fixed), we employ the \textit{SELF} arc generator in order to produce a graph with a single loop on each vertex.

Parts (A) and (B) of Figure 5.357 respectively show the initial and final graph associated with the Example slot. Since we use the \textit{NARC} graph property, the loops of the final graph are stressed in bold. The \textit{EXACTLY} constraint holds since exactly two variables are assigned value 4.

![Diagram](image)

Figure 5.357: Initial and final graph of the \textit{EXACTLY} constraint
Automaton

Figure 5.358 depicts the automaton associated with the EXACTLY constraint. To each variable \( \text{VAR}_i \) of the collection \( \text{VARIABLES} \) corresponds a 0-1 signature variable \( S_i \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i = \text{VALUE} \Leftrightarrow S_i \).

\[
\begin{align*}
\text{VAR}_i \neq \text{VALUE} & \quad \{ C \leftarrow 0 \} \quad \text{VAR}_i = \text{VALUE}, \quad \{ C \leftarrow C + 1 \} \\
\end{align*}
\]

Glue matrix where \( \overrightarrow{C} \) and \( \overleftarrow{C} \) resp. represent the counter value \( C \) at the end of a prefix and at the end of the corresponding reverse suffix that partitions the sequence \( \text{VARIABLES} \).

Figure 5.358: Automaton (with one counter) of the EXACTLY constraint and its glue matrix

Figure 5.359: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the EXACTLY constraint: since all states variables \( Q_0, Q_1, \ldots, Q_n \) are fixed to the unique state \( s \) of the automaton, the transitions constraints share only the counter variable \( C \) and the constraint network is Berge-acyclic
5.158  \texttt{FIRST\_VALUE\_DIFF\_0}

\textbf{Origin}  Paparazzi puzzle

\textbf{Constraint}  \texttt{FIRST\_VALUE\_DIFF\_0(VAR, VARIABLES)}

\textbf{Synonyms}  \texttt{FIRST\_VALUE\_DIFF\_FROM\_0}, \texttt{FIRST\_VALUE\_DIFFERENT\_FROM\_0}.

\textbf{Arguments}  \begin{align*}
\text{VAR} & : \text{dvar} \\
\text{VARIABLES} & : \text{collection(var−dvar)}
\end{align*}

\textbf{Restrictions}  \begin{align*}
\text{VAR} & \neq 0 \\
|\text{VARIABLES}| & \geq 1 \\
\text{required}(\text{VARIABLES}, \text{var})
\end{align*}

\textbf{Purpose}  \text{VAR} is equal to the first non-zero variable of the collection \text{VARIABLES}.

\textbf{Example}  \begin{align*}
(8, (0, 0, 8, 0, 5)) \\
(4, (4, 0, 8, 0, 5))
\end{align*}

\textbf{Typical}  \begin{align*}
|\text{VARIABLES}| & > 1 \\
\text{minval}(\text{VARIABLES}.\text{var}) & < 0 \\
\text{maxval}(\text{VARIABLES}.\text{var}) & > 1 \\
|\text{VARIABLES}|−\text{AMONG\_DIFF\_0}(\text{VARIABLES}.\text{var}) & \geq 1 \\
\bigvee \left( \begin{array}{c}
|\text{VARIABLES}| \leq 4, \\
|\text{VARIABLES}|−\text{AMONG\_DIFF\_0}(\text{VARIABLES}.\text{var}) > 1
\end{array} \right)
\end{align*}

\textbf{Typical model}  \begin{align*}
\text{nval}(\text{VARIABLES}.\text{var}) & > 2 \\
\text{ATLEAST}(2, \text{VARIABLES}, 0)
\end{align*}

\textbf{Arg. properties}  Functional dependency: \text{VAR} determined by \text{VARIABLES}.

Solution count for FIRST_VALUE_DIFF_0: domains 0..n

Solution density for FIRST_VALUE_DIFF_0

Parameter value as fraction of length
See also

implies: BETWEEN_MIN_MAX.

Keywords

characteristic of a constraint: joker value, automaton, automaton with counters.
modelling: functional dependency.
Automaton

Figure 5.360 depicts an automaton that only accepts all the solutions to the FIRST_VALUE_DIFF_0 constraint. This automaton uses a counter in order to record the value of the first non-zero variable $VAR_i$ already encountered. To each variable $VAR_i$ of the collection VARIABLES corresponds a 0-1 signature variable $S_i$. The following signature constraint links $VAR_i$ and $S_i$: $VAR_i \neq 0 \iff S_i$.

\begin{align*}
\{C \leftarrow 0\} & \quad \rightarrow \quad \text{VAR}_i = 0 \\
\text{VAR}_i \neq 0, \quad \{C \leftarrow \text{VAR}_i\} & \quad \rightarrow \quad \text{VAR}_i = 0 \\
\text{VAR}_i \neq 0 & \quad \rightarrow \quad \text{VAR}_i = 0
\end{align*}

Figure 5.361: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the FIRST_VALUE_DIFF_0 constraint
5.159  FULL_GROUP

DESCRIPTION

Origin
Inspired by GROUP

Constraint
FULL_GROUP
NGROUP, MIN_SIZE, MAX_SIZE, MIN_DIST, MAX_DIST, NVAL, VARIABLES, VALUES

Synonym
GROUP_WITHOUT_BORDER.

Arguments
NGROUP : dvar
MIN_SIZE : dvar
MAX_SIZE : dvar
MIN_DIST : dvar
MAX_DIST : dvar
NVAL : dvar
VARIABLES : collection(var−dvar)
VALUES : collection(val−int)

Restrictions
NGROUP ≥ 0
MIN_SIZE ≥ 0
MAX_SIZE ≥ MIN_SIZE
MIN_DIST ≥ 0
MAX_DIST ≥ MIN_DIST
MAX_DIST ≤ |VARIABLES| − 2
NVAL ≥ MAX_SIZE
NVAL ≥ NGROUP
NVAL ≤ |VARIABLES| − 2
required(VARIABLES, var)
required.VALUES, val)
distinct(VALUES, val)
Let $n$ be the number of variables of the collection $\text{VARIABLES}$. Let $X_i, X_{i+1}, \ldots, X_j$ ($1 \leq i \leq j \leq n$) be consecutive variables of the collection of variables $\text{VARIABLES}$ such that all the following conditions simultaneously apply:

- All variables $X_i, \ldots, X_j$ take their values in the set of values $\text{VALUES}$,
- $i = 1$ or $X_{i-1}$ does not take a value in $\text{VALUES}$,
- $j = n$ or $X_{j+1}$ does not take a value in $\text{VALUES}$.

We call such a sequence of variables a group. A full group is a group that neither starts at position 1 nor ends at position $n$. Similarly an anti-full group is a maximum sequence of variables that are not assigned any value from $\text{VALUES}$ that neither starts at position 1 nor ends at position $n$.

The constraint $\text{FULL\_GROUP}$ is true if all the following conditions hold:

- There are exactly $\text{NGROUP}$ full groups of variables,
- $\text{MIN\_SIZE}$ is the number of variables of the smallest full group,
- $\text{MAX\_SIZE}$ is the number of variables of the largest full group,
- $\text{MIN\_DIST}$ is the number of variables of the smallest anti-full group,
- $\text{MAX\_DIST}$ is the number of variables of the largest anti-full group,
- $\text{NVAL}$ is the number of variables that belong to a full group.

**Example**

$\langle 2, 2, 3, 1, 1, 5, \langle 0, 1, 2, 6, 2, 7, 4, 8, 9 \rangle, \langle 0, 2, 4, 6, 8 \rangle \rangle$

Given the fact that full groups are formed by even values in $\{0, 2, 4, 6, 8\}$ (i.e., values expressed by the $\text{VALUES}$ collection), the $\text{FULL\_GROUP}$ constraint holds since:

- Its first argument, $\text{NGROUP}$, is set to value 2 since the sequence $0 \ 1 \ 2 \ 6 \ 2 \ 7 \ 4 \ 8 \ 9$ contains two full groups of even values (i.e., group $2 \ 6 \ 2$ and group $4 \ 8$). Note that the first 0 is not a full group since it is located at the first position of the sequence.
- Its second argument, $\text{MIN\_SIZE}$, is set to value 2 since the smallest full group of even values involves only two elements (i.e., the full group $4 \ 8$).
- Its third argument, $\text{MAX\_SIZE}$, is set to value 3 since the largest full group of even values involves three elements (i.e., the full group $2 \ 6 \ 2$).
- Its fourth argument, $\text{MIN\_DIST}$, is set to value 1 since the smallest anti-full groups involve a single element (i.e., the anti-full groups 1 and 7).
- Its fifth argument, $\text{MAX\_DIST}$, is set to value 1 since the largest anti-full groups involve a single element (i.e., the anti-full groups 1 and 7).
- Its sixth argument, $\text{NVAL}$, is set to value 5 since the total number of even values part of a full group of the sequence $0 \ 1 \ 2 \ 6 \ 2 \ 7 \ 4 \ 8 \ 9$ is equal to 5 (i.e., elements 2, 6, 2, 4 and 8).
**Typical**

NGROUP > 0
MIN_SIZE > 0
MAX_SIZE > MIN_SIZE
MIN_DIST > 0
MAX_DIST > MIN_DIST
MAX_DIST < |VARIABLES|
NVAL > MAX_SIZE
NVAL > NGROUP
NVAL < |VARIABLES|
|VARIABLES| > 1
range(VARIABLES.var) > 1
|VALUES| > 0
|VARIABLES| > |VALUES|

**Symmetries**

- Items of VARIABLES can be reversed.
- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

**Arg. properties**

- Functional dependency: NGROUP determined by VARIABLES and VALUES.
- Functional dependency: MIN_SIZE determined by VARIABLES and VALUES.
- Functional dependency: MAX_SIZE determined by VARIABLES and VALUES.
- Functional dependency: MIN_DIST determined by VARIABLES and VALUES.
- Functional dependency: MAX_DIST determined by VARIABLES and VALUES.
- Functional dependency: NVAL determined by VARIABLES and VALUES.

**See also**

- **common keyword**: GROUP (timetabling constraint, sequence).

**Keywords**

- **characteristic of a constraint**: automaton, automaton with counters, automaton with same input symbol.
- **combinatorial object**: sequence.
- **constraint arguments**: reverse of a constraint, pure functional dependency.
- **constraint network structure**: alpha-acyclic constraint network(2), alpha-acyclic constraint network(3).
- **constraint type**: timetabling constraint.
- **filtering**: glue matrix.
- **modelling**: functional dependency.
Automaton

Figures 5.362, 5.364, 5.366, 5.368, 5.370 and 5.372 depict the different automata associated with the FULL\_GROUP constraint. For the automata that respectively compute \(\text{NGROUP}\), \(\text{MIN}\_\text{SIZE}\), \(\text{MAX}\_\text{SIZE}\), \(\text{MIN}\_\text{DIST}\), \(\text{MAX}\_\text{DIST}\) and \(\text{NVAL}\) we have a 0-1 signature variable \(S_i\) for each variable \(\text{VAR}_i\) of the collection \(\text{VARIABLES}\). The following signature constraint links \(\text{VAR}_i\) and \(S_i\): \(\text{VAR}_i \in \text{VALUES} \leftrightarrow S_i\).

\[
\{C \leftarrow 0\}
\]

\[
\begin{array}{c}

5.160  GCD

Origin                  [146]
Constraint              GCD(X, Y, Z)
Arguments
  X : dvar
  Y : dvar
  Z : dvar
Restrictions
  X > 0
  Y > 0
  Z > 0
Purpose
  Enforce the fact that Z is the greatest common divisor of X and Y.
Example
  (24, 60, 12)
The GCD constraint holds since 12 is the greatest common divisor of 24 and 60.
Typical
  X > 1
  Y > 1
Symmetry
  Arguments are permutable w.r.t. permutation (X, Y) (Z).
Arg. properties
  Functional dependency: X determined by Y and Z.
Algorithm
  In [146] a filtering algorithm for the GCD constraint was automatically derived from the
  Euclidian algorithm by using constructive disjunction and abstract interpretation in order
  to approximate the behaviour of the while loop of the Euclidian algorithm.
See also
  common keyword: POWER (abstract interpretation).
Keywords
  constraint arguments: ternary constraint, pure functional dependency.
  constraint type: arithmetic constraint, predefined constraint.
  filtering: abstract interpretation.
  modelling: functional dependency.
## 5.161 GEOST

### Origin
Generalisation of DIFFN.

### Constraint
GEOST(K, OBJECTS, SBOXES)

### Types
- **VARIABLES**: collection(v-dvar)
- **INTEGERS**: collection(v-int)
- **POSITIVES**: collection(v-int)

### Arguments
- **K**: int
- **OBJECTS**: collection(oid-int,sid-dvar,x-VARIABLES)
- **SBOXES**: collection(sid-int,t-INTEGERS,l-POSITIVES)

### Restrictions
- |VARIABLES| ≥ 1
- |INTEGERS| ≥ 1
- |POSITIVES| ≥ 1
- required(VARIABLES,v)
- |VARIABLES| = K
- required(INTEGERS,v)
- |INTEGERS| = K
- required(POSITIVES,v)
- |POSITIVES| = K
- POSITIVES.v > 0
- K > 0
- required(OBJECTS,[oid,sid,x])
- distinct(OBJECTS,oid)
- OBJECTS.oid ≥ 1
- OBJECTS.oid ≤ |OBJECTS|
- OBJECTS.sid ≥ 1
- OBJECTS.sid ≤ |SBOXES|
- |SBOXES| ≥ 1
- required(SBOXES,[sid,t,1])
- SBOXES.sid ≥ 1
- SBOXES.sid ≤ |SBOXES|
- do_not_overlap(SBOXES)
Holds if, for each pair of objects \((O_i, O_j), i < j\), \(O_i\) and \(O_j\) do not overlap with respect to a set of dimensions \(\{1, 2, \ldots, K\}\). \(O_i\) and \(O_j\) are objects that take a shape among a set of shapes. Each shape is defined as a finite set of shifted boxes, where each shifted box is described by a box in a \(K\)-dimensional space at a given offset (from the origin of the shape) with given sizes that are all strictly greater than 0. More precisely, a shifted box is an entity defined by its shape id \(\text{sid}\), shift offset \(\text{t}\), and sizes \(\text{s}\). Then, a shape is defined as the union of shifted boxes sharing the same shape id. An object is an entity defined by its unique object identifier \(\text{oid}\), shape id \(\text{sid}\) and origin \(\text{x}\).

An object \(O_i\) does not overlap an object \(O_j\) with respect to the set of dimensions \(\{1, 2, \ldots, K\}\) if and only if for all shifted box \(s_i\) associated with \(O_i\) and for all shifted box \(s_j\) associated with \(O_j\), there exists a dimension \(d \in \{1, 2, \ldots, K\}\) such that the start of \(s_i\) in dimension \(d\) is greater than or equal to the end of \(s_j\) in dimension \(d\), or the start of \(s_j\) in dimension \(d\) is greater than or equal to the end of \(s_i\) in dimension \(d\).

\[
\begin{align*}
\text{Examples:} & \\
& \begin{pmatrix}
\text{oid} - 1 & \text{sid} - 1 & \text{x} - (1, 2), \\
\text{oid} - 2 & \text{sid} - 5 & \text{x} - (2, 1), \\
\text{oid} - 3 & \text{sid} - 8 & \text{x} - (4, 1)
\end{pmatrix}, \\
& \begin{pmatrix}
\text{sid} - 1 & \text{t} - (0, 0) & \text{l} - (2, 1), \\
\text{sid} - 1 & \text{t} - (0, 1) & \text{l} - (1, 2), \\
\text{sid} - 1 & \text{t} - (1, 2) & \text{l} - (3, 1), \\
\text{sid} - 2 & \text{t} - (0, 0) & \text{l} - (3, 1), \\
\text{sid} - 2 & \text{t} - (0, 1) & \text{l} - (1, 3), \\
\text{sid} - 2 & \text{t} - (2, 1) & \text{l} - (1, 1), \\
\text{sid} - 3 & \text{t} - (0, 0) & \text{l} - (2, 1), \\
\text{sid} - 3 & \text{t} - (1, 1) & \text{l} - (1, 2), \\
\text{sid} - 3 & \text{t} - (2, 2) & \text{l} - (3, 1), \\
\text{sid} - 4 & \text{t} - (0, 0) & \text{l} - (3, 1), \\
\text{sid} - 4 & \text{t} - (0, 1) & \text{l} - (1, 1), \\
\text{sid} - 4 & \text{t} - (2, 1) & \text{l} - (1, 3), \\
\text{sid} - 5 & \text{t} - (0, 0) & \text{l} - (2, 1), \\
\text{sid} - 5 & \text{t} - (1, 1) & \text{l} - (1, 1), \\
\text{sid} - 5 & \text{t} - (0, 2) & \text{l} - (2, 1), \\
\text{sid} - 6 & \text{t} - (0, 0) & \text{l} - (3, 1), \\
\text{sid} - 6 & \text{t} - (0, 1) & \text{l} - (1, 1), \\
\text{sid} - 6 & \text{t} - (2, 1) & \text{l} - (1, 1), \\
\text{sid} - 7 & \text{t} - (0, 0) & \text{l} - (3, 2), \\
\text{sid} - 8 & \text{t} - (0, 0) & \text{l} - (2, 3)
\end{pmatrix}
\end{align*}
\]

Parts (A), (B) and (C) of Figure 5.374 respectively represent the potential shapes associated with the three objects of the example. Part (D) shows the position of the three objects of the example, where the first, second and third objects were respectively assigned shapes 1, 5 and 8. The coordinates of the leftmost lowest corner of each object are stressed in bold. The \textit{GEOST} constraint holds since the three objects do not overlap (i.e., see part (D) if Figure 5.374).

Typical $|\text{OBJECTS}| > 1$
Potential shapes for object $O_1$ (A)

Potential shapes for object $O_2$ (B)

Potential shapes for object $O_3$ (C)

Figure 5.374: (D) The three non-overlapping objects $O_1$, $O_2$, $O_3$ of the Example slot respectively assigned shapes $S_1$, $S_5$, $S_8$; (A), (B), (C) shapes $S_1$, $S_2$, $S_3$, $S_4$, $S_5$, $S_6$, $S_7$ and $S_8$ are respectively made up from $3$, $3$, $3$, $3$, $3$, $3$ and $1$ disjoint shifted box.

**Symmetries**

- Items of $O$BJECTS are **permutable**.
- Items of $S$BOXES are **permutable**.
- Items of $O$BJECTS.x, $S$BOXES.t and $S$BOXES.l are **permutable** (**same permutation used**).
- $S$BOXES.l.v can be **decreased** to any value $\geq 1$.

**Usage**

The GEOST constraint allows one to model directly a large number of placement problems.

**Remark**

In the two-dimensional case, when rectangles heights are all equal to one and when rectangles starts in the first dimension are all fixed, the GEOST constraint can be rewritten as a $K$,$ALLDIFFERENT constraint corresponding to a system of $ALLDIFFERENT constraints derived from the maximum cliques of the corresponding interval graph.

**Algorithm**

A sweep-based filtering algorithm for this constraint is described in [42]. Unlike previous sweep filtering algorithms which move a line for finding a feasible position for the origin of an object, this algorithm performs a recursive traversal of the multidimensional placement space. It explores all points of the domain of the origin of the object under focus, one by one, in increasing lexicographic order, until a point is found that is not infeasible for any non-overlapping constraints. To make the search efficient, instead of moving each time to the successor point, the search is arranged so that it skips points that are known to be infeasible for some non-overlapping constraint.
Within the context of breaking symmetries six different ways of integrating within GEOST a chain of lexicographical ordering constraints like LEX_CHAIN_LESS for enforcing a lexicographic ordering on the origin coordinates of identical objects, are described in [3].

**Systems**

GEOST in Choco, GEOST in JaCoP, GEOST in SICStus.

**See also**

common keyword: CALENDAR (multi-site employee scheduling with calendar constraints, scheduling with machine choice, calendars and preemption), DIFFN (geometrical constraint, non-overlapping), LEX_CHAIN_LESS, LEX_CHAIN_LESSEQ (symmetry), NON OVERLAP_SBOXES (geometrical constraint, non-overlapping), VISIBLE (geometrical constraint, sweep).

generalisation: GEOST_TIME (temporal dimension added to geometrical dimensions).

specialisation: K_ALLDIFFERENT (when rectangles heights are all equal to 1 and rectangles starts in the first dimension are all fixed), LEX_ALLDIFFERENT (object replaced by vector).

\(s\) for start, \(d\) for duration, \(e\) for end

Parts (A), (B) and (C) of Figure 5.375 respectively represent the potential shapes
associated with the three objects of the example. Part (D) shows the position of the three objects of the example, where the first, second and third objects were respectively assigned shapes 1, 5 and 8. The coordinates of the leftmost lowest corner of each object are stressed in bold. The GEOST\_TIME constraint holds since the three objects do not overlap: even though the time intervals associated with each object overlap (i.e., they are in fact identical), their corresponding shapes do not overlap (i.e., see part (D) if Figure 5.375).

Figure 5.375: (D) The three non-overlapping objects $O_1$, $O_2$, $O_3$ of the Example slot respectively assigned shapes $S_1$, $S_5$, $S_8$; (A), (B), (C) shapes $S_1$, $S_2$, $S_3$, $S_4$, $S_5$, $S_6$, $S_7$ and $S_8$ are respectively made up from 3, 3, 3, 3, 3, 1 and 1 disjoint shifted box.
• The first case (A) corresponds to a non-overlapping constraint among three segments (or three tasks in disjunction).

• The second, third and fourth cases (B,C,D) correspond to a non-overlapping constraint between rectangles where (B) and (C) are special cases where the sizes of all rectangles in the second dimension are equal to 1; this can be interpreted as a machine assignment problem where each rectangle corresponds to a non-pre-emptive task that has to be placed in time and assigned to a specific machine so that no two tasks assigned to the same machine overlap in time. In Part (B) the duration of each task is fixed, while in Part (C) the duration depends on the machine to which the task is actually assigned. This dependence can be expressed by the ELEMENT constraint, which specifies the dependence between the shape variable and the assignment variable of each task.

• The fifth case (E) corresponds to a non-overlapping constraint between rectangles where each rectangle can have two orientations. This is achieved by associating with each rectangle two shapes of respective sizes \( l \times h \) and \( h \times l \). Since their orientations is not initially fixed, an ELEMENT_LESSEQ constraint can be used for enforcing the three rectangles to be included within the bounding box defined by the origin’s coordinates 1, 1 and sizes 8, 3.

• The sixth case (F) corresponds to a non-overlapping constraint between more complex objects where each object is described by a given set of rectangles.

• The seventh case (G) describes a rectangle placement problem where one has to first assign each rectangle to a strip so that all rectangles that are assigned to the same strip do not overlap.

• The eighth case (H) corresponds to a non-overlapping constraint between parallelepipeds.

• The ninth case (I) can be interpreted as a non-overlapping constraint between parallelepipeds that are assigned to the same container. The first dimension corresponds to the identifier of the container, while the next three dimensions are associated with the position of a parallelepiped inside a container.

• Finally the tenth case (J) describes a rectangle placement problem over three consecutive time-slots: rectangles assigned to the same time-slot should not overlap in time. We initially start with the three rectangles 1, 2 and 3. Rectangle 3 is no more present at instant 2 (the arrow \( \downarrow \) within rectangle 3 at time 1 indicates that rectangle 3 will disappear at the next time-point), while rectangle 4 appears at instant 2 (the arrow \( \uparrow \) within rectangle 4 at time 2 denotes the fact that the rectangle 4 appears at instant 2). Finally rectangle 2 disappears at instant 3 and is replaced by rectangle 5.

Algorithm

A sweep-based filtering algorithm for this constraint is described in [42]. Unlike previous sweep filtering algorithms which move a line for finding a feasible position for the origin of an object, this algorithm performs a recursive traversal of the multidimensional placement space. It explores all points of the domain of the origin of the object under focus, one by one, in increasing lexicographic order, until a point is found that is not infeasible for any non-overlapping constraints. To make the search efficient, instead of moving each time to the successor point, the search is arranged so that it skips points that are known to be infeasible for some non-overlapping constraint.

Systems

GEOST in Choco, GEOST in JaCoP.
See also: common keyword: DIFFN, NON_OVERLAP_SBOXES (geometrical constraint, non-overlapping), VISIBLE (geometrical constraint, sweep).

specialisation: GEOST (temporal dimension removed).

Keywords

constraint type: decomposition, timetabling constraint, predefined constraint.

filtering: sweep.

geometry: geometrical constraint, non-overlapping.

modelling: assignment dimension, assignment to the same set of values, assigning and scheduling tasks that run in parallel, disjunction.

modelling exercises: assignment to the same set of values, assigning and scheduling tasks that run in parallel.
tasks in disjunction

(A)

tasks assigned to the same machine are in disjunction (fixed duration)

(B)

tasks assigned to the same machine are in disjunction (machine dependent duration)

(C)

non-overlapping rectangles (fixed orientation)

(D)

non-overlapping rectangles (90° rotation)

(E)

non-overlapping compound objects

(F)

non-overlapping rectangles that are assigned to the same plate

(G)

non-overlapping parallelepipeds

(H)

non-overlapping parallelepipeds that are assigned to the same container

(I)

moving rectangles on a plate:
- rectangle ◊ gets out at instant 1
- rectangle □ gets out at instant 2
- rectangle △ gets in at instant 2
- rectangle □ gets in at instant 3

5.163 GEQ

Origin
Arithmetic.

Constraint
GEQ(VAR1, VAR2)

Synonyms
REL, XGTEQY.

Arguments
VAR1 : dvar
VAR2 : dvar

Purpose
Enforce the fact that the first variable is greater than or equal to the second variable.

Example
(8, 1)
The GEQ constraint holds since 8 is greater than or equal to 1.

Symmetries
• VAR1 can be replaced by any value ≥ VAR2.
• VAR2 can be replaced by any value ≤ VAR1.

Systems
GEQ in Choco, REL in Gecode, XGTEQY in JaCoP, #>= in SICStus.

See also
common keyword: NEQ(binary constraint, arithmetic constraint).
generalisation: GEQ_CST(constant added).
implied by: ABS_VALUE, EQ, GT.
implies (if swap arguments): LEQ.
negation: LT.

Keywords
constraint arguments: binary constraint.
constraint type: predefined constraint, arithmetic constraint.
filtering: arc-consistency.
### 5.164 GEQ_CST

**DESCRIPTION**

**Origin**
Arithmetic.

**Constraint**

GEQ_CST(VAR1, VAR2, CST2)

**Arguments**

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>VAR1</td>
<td>dvar</td>
</tr>
<tr>
<td>VAR2</td>
<td>dvar</td>
</tr>
<tr>
<td>CST2</td>
<td>int</td>
</tr>
</tbody>
</table>

**Purpose**
Enforce the fact that the first variable is greater than or equal to the sum of the second variable and the constant.

**Example**

(8, 1, 7)

The GEQ_CST constraint holds since 8 is greater than or equal to 1 + 7.

**Typical**

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>CST2 ≠ 0</td>
</tr>
<tr>
<td>VAR1 &gt; VAR2 + CST2</td>
</tr>
</tbody>
</table>

**Symmetries**

- Arguments are permutable w.r.t. permutation (VAR1) (VAR2, CST2).
- VAR1 can be replaced by any value ≥ VAR2 + CST2.
- VAR2 can be replaced by any value ≤ VAR1 − CST2.
- CST2 can be replaced by any value ≤ VAR1 − VAR2.

**See also**

- common keyword: LEQ_CST (binary constraint, arithmetic constraint).
- implied by: EQ_CST.
- specialisation: GEQ (constant set to 0).

**Keywords**

- constraint arguments: binary constraint.
- constraint type: predefined constraint, arithmetic constraint.
- filtering: arc-consistency.
5.165  GLOBAL_CARDINALITY

**Origin**  
CHARME [309]

**Constraint**  
GLOBAL_CARDINALITY(VARIABLES, VALUES)

**Synonyms**  
COUNT, DISTRIBUTE, DISTRIBUTION, GCC, CARD_VAR_GCC, EGCC, EXTENDED_GLOBAL_CARDINALITY.

**Arguments**  
VARIABLES : collection(var−dvar)  
VALUES : collection(val−int,noccurrence−dvar)

**Restrictions**  
required(VARIABLES, var)  
required(values, [val, noccurrence])  
distinct(values, val)  
VALUES.noccurrence ≥ 0  
VALUES.noccurrence ≤ |VARIABLES|

**Purpose**  
Each value VALUES[i].val (with i ∈ [1, |VALUES|]) should be taken by exactly VALUES[i].noccurrence variables of the VARIABLES collection.

**Example**  
\[
\begin{pmatrix}
(3,3,8,6), \\
\begin{pmatrix}
val - 3 & noccurrence - 2, \\
val - 5 & noccurrence - 0, \\
val - 6 & noccurrence - 1
\end{pmatrix}
\end{pmatrix}
\]

The GLOBAL_CARDINALITY constraint holds since values 3, 5 and 6 respectively occur 2, 0 and 1 times within the collection (3,3,8,6) and since no restriction was specified for value 8.

**All solutions**  
Figure 5.377 gives all solutions to the following non ground instance of the GLOBAL_CARDINALITY constraint: V₁ ∈ [3, 4], V₂ ∈ [2, 3], V₃ ∈ [1, 2], V₄ ∈ [2, 4], V₅ ∈ [2, 3], V₆ ∈ [1, 2], O₁ ∈ [1, 1], O₂ ∈ [2, 3], O₃ ∈ [0, 1], O₄ ∈ [2, 3], GLOBAL_CARDINALITY((V₁, V₂, V₃, V₄, V₅, V₆), (1 O₁, 2 O₂, 3 O₃, 4 O₄)).

**Typical**  
|VARIABLES| > 1  
range(VARIABLES.var) > 1  
|VALUES| > 1  
|VARIABLES| ≥ |VALUES|  
minval(VARIABLES.var) = 0 \in attr(VARIABLES, var, VALUES, val)
Figure 5.377: All solutions corresponding to the non ground example of the GLOBAL_CARDINALITY constraint of the All solutions slot

Symmetries

- Items of VARIABLES are permutable.
- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.

Arg. properties

- Functional dependency: VALUES.noccurrence determined by VARIABLES and VALUES.val.
- Contractible wrt. VALUES.

Usage

We show how to use the GLOBAL_CARDINALITY constraint in order to model the magic series problem [426, page 155] with a single GLOBAL_CARDINALITY constraint. A non-empty finite series \( S = (s_0, s_1, \ldots, s_n) \) is magic if and only if there are \( s_i \) occurrences of \( i \) in \( S \) for each integer \( i \) ranging from 0 to \( n \). This leads to the following model:

\[
\begin{bmatrix}
\langle \text{var} - s_0, \text{var} - s_1, \ldots, \text{var} - s_n \rangle, \\
\text{val} - 0 & \text{noccurrence} - s_0, \\
\text{val} - 1 & \text{noccurrence} - s_1, \\
\vdots \\
\text{val} - n & \text{noccurrence} - s_n,
\end{bmatrix}
\]

Remark

This is a generalised form of the original GLOBAL_CARDINALITY constraint: in the original GLOBAL_CARDINALITY constraint [353], one specifies for each value its minimum and maximum number of occurrences (i.e., see GLOBAL_CARDINALITY_LOW_UP). Here we give for each value \( v \) a domain variable that indicates how many times \( v \) is actually used. By setting the minimum and maximum values of this variable to the appropriate constants we can express the same thing as in the original GLOBAL_CARDINALITY constraint. However, as shown in the magic series problem, we can also use this variable in other constraints. By reduction from \( 3\text{-SAT} \), Claude-Guy Quimper shows in [342] that it is NP-hard to achieve arc-consistency for the count variables.
A last difference from the original GLOBAL_CARDINALITY constraint is that there is no constraint on the values that are not explicitly mentioned in the VALUES collection. In the original GLOBAL_CARDINALITY these values could not be assigned to the variables of the VARIABLES collection. However allowing values that are not mentioned in VALUES to be assigned to variables of VARIABLES can potentially avoid mentioning a huge number of unconstrained values in the VALUES collection, and as a side effect, prevent possibly generating a dense graph (i.e., see DFS-bottleneck) for the corresponding underlying flow model.

Within [92] the GLOBAL_CARDINALITY constraint is called DISTRIBUTION. Within [361] the GLOBAL_CARDINALITY constraint is called CARD_VAR_GCC. Within [76] the GLOBAL_CARDINALITY constraint is called EGCC or RGCC. This later case corresponds to the fact that some variables are duplicated within the VARIABLES collection.

The GLOBAL_CARDINALITY constraint can be seen as a system (i.e., a conjunction) of AMONG constraints.

When all count variables (i.e., the variables VALUES[i].noccurrence with $i \in [1,|VALUES|]$ do not occur in any other constraints of the problem, it may be operationally more efficient to replace the GLOBAL_CARDINALITY constraint by a GLOBAL_CARDINALITY_LOW_UP constraint where each count variable VALUES[i].noccurrence is replaced by the corresponding interval [$VALUES[i].noccurrence, VALUES[i].noccurrence$]. This stands for two reasons:

- First, by using a GLOBAL_CARDINALITY_LOW_UP constraint rather than a GLOBAL_CARDINALITY constraint, we avoid the filtering algorithm related to the count variables.
- Second, unlike the GLOBAL_CARDINALITY constraint where we need to fix all its variables to get entailment, the GLOBAL_CARDINALITY_LOW_UP constraint can be entailed before all its variables get fixed. As a result, this potentially avoid unnecessary calls to its filtering algorithm.

When all values that can be assigned to the variables of the VARIABLES collection occur in the val attribute of the VALUES collection, two implicit necessary conditions inferred by double counting with the GLOBAL_CARDINALITY constraint are depicted by the following expressions:

$$|VARIABLES| = \sum_{i=1}^{|VALUES|} VALUES[i].noccurrence$$

$$\sum_{i=1}^{|VARIABLES|} VARIABLES[i].var = \sum_{i=1}^{|VALUES|} VALUES[i].val \cdot VALUES[i].noccurrence$$

Within [328, pages 50–51] the previous condition where terms involving identical variables are grouped together (i.e., rule 5 of MALICE [327]) is mentioned as a crucial deduction rule for the autoref problem.

\(^7\) Of course one could also, while generating a flow model, detect all unconstrained values in order to generate a single vertex in the flow model for the set of unconstrained values.

\(^8\) Note that such necessary conditions can be derived by assigning an integer weight to each value [396], e.g. 1 for the first condition, the value itself for the second condition.
W.-J. van Hoeve *et al.* present two soft versions of the `GLOBAL_CARDINALITY` constraint in [435].

In **MiniZinc** ([http://www.minizinc.org/](http://www.minizinc.org/)) there is also a `DISTRIBUTE` constraint where the `val` attribute is not necessarily initially fixed and where a same value may occur more than once. There is also a `GLOBAL_CARDINALITY_CLOSED` constraint where all variables must be assigned a value from the `val` attribute.

**Algorithm**

A *flow* algorithm that handles the original `GLOBAL_CARDINALITY` constraint is described in [353]. The two approaches that were used to design `bound-consistency` algorithms for `ALLDIFFERENT` were generalised for the `GLOBAL_CARDINALITY` constraint. The algorithm in [345] identifies *Hall intervals* and the one in [244] exploits convexity to achieve a fast implementation of the flow-based `arc-consistency` algorithm. The later algorithm can also compute `bound-consistency` for the count variables [245, 242]. An improved algorithm for achieving `arc-consistency` is described in [344].

**Systems**

`GLOBAL_CARDINALITY` in **Choco**, `COUNT` in **Gecode**, `GCC` in **JaCoP**, `GLOBAL_CARDINALITY` in **MiniZinc**, `GLOBAL_CARDINALITY` in **SICStus**.

**Keywords**

- **application area**: assignment.
- **characteristic of a constraint**: core, automaton, automaton with array of counters.
- **complexity**: 3-SAT.
**constraint arguments:** pure functional dependency.
**constraint type:** value constraint, counting constraint, system of constraints.
**filtering:** Hall interval, bound-consistency, flow, duplicated variables, DFS-bottleneck.
**modelling:** functional dependency.
**modelling exercises:** magic series.
**puzzles:** magic series, autoref.

**Cond. implications**

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{minval}(\text{VARIABLES}\.\text{var}) = 0 \)
  implies \( \text{AND}(\text{VAR}, \text{VARIABLES}) \)
  when \( \text{VAR} = 0 \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{maxval}(\text{VARIABLES}\.\text{var}) = 1 \)
  implies \( \text{OR}(\text{VAR}, \text{VARIABLES}) \)
  when \( \text{VAR} = 1 \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{minval}(\text{VARIABLES}\.\text{var}) > 0 \)
  implies \( \text{MIN_SIZE_FULL_ZERO_STRETCH}(\text{MINSIZE}, \text{VARIABLES}) \)
  when \( \text{MINSIZE} = |\text{VARIABLES}| \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{maxval}(\text{VARIABLES}\.\text{var}) < 0 \)
  implies \( \text{MIN_SIZE_FULL_ZERO_STRETCH}(\text{MINSIZE}, \text{VARIABLES}) \)
  when \( \text{MINSIZE} = |\text{VARIABLES}| \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{range}(\text{VALUES}\.\text{val}) = \text{nval}(\text{VALUES}\.\text{val}) \)
  and \( \text{minval}(\text{VALUES}\.\text{val}) \leq \text{minval}(\text{VARIABLES}\.\text{var}) \)
  and \( \text{maxval}(\text{VALUES}\.\text{val}) \geq \text{maxval}(\text{VARIABLES}\.\text{var}) \)
  implies \( \text{AMONG_DIFF_0}(\text{NVAR}, \text{VARIABLES}) \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{range}(\text{VALUES}\.\text{val}) = \text{nval}(\text{VALUES}\.\text{val}) \)
  and \( \text{minval}(\text{VALUES}\.\text{val}) \leq \text{minval}(\text{VARIABLES}\.\text{var}) \)
  and \( \text{maxval}(\text{VALUES}\.\text{val}) \geq \text{maxval}(\text{VARIABLES}\.\text{var}) \)
  implies \( \text{ATMOST_NVALUE}(\text{NVAL}, \text{VARIABLES}) \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{range}(\text{VALUES}\.\text{noccurrence}) = 1 \)
  and \( \text{range}(\text{VALUES}\.\text{val}) = \text{nval}(\text{VALUES}\.\text{val}) \)
  and \( \text{minval}(\text{VALUES}\.\text{val}) = \text{minval}(\text{VARIABLES}\.\text{var}) \)
  and \( \text{maxval}(\text{VALUES}\.\text{val}) = \text{maxval}(\text{VARIABLES}\.\text{var}) \)
  implies \( \text{BALANCE}(\text{BALANCE}, \text{VARIABLES}) \)
  when \( \text{BALANCE} = 0 \).

- **GLOBAL_CARDINALITY**(VARIABLES, VALUES)
  with \( \text{range}(\text{VALUES}\.\text{val}) = \text{nval}(\text{VALUES}\.\text{val}) \)
  and \( \text{minval}(\text{VALUES}\.\text{val}) \leq \text{minval}(\text{VARIABLES}\.\text{var}) \)
  and \( \text{maxval}(\text{VALUES}\.\text{val}) \geq \text{maxval}(\text{VARIABLES}\.\text{var}) \)
  implies \( \text{MAX_N}(\text{MAX}, \text{RANK}, \text{VARIABLES}) \).
- **GLOBAL_CARDINALITY** (VARIABLES, VALUES)
  with \( \text{range} \text{(VALUES.val)} = \text{nval} \text{(VALUES.val)} \)
  and \( \text{minval} \text{(VALUES.val)} \leq \text{minval} \text{(VARIABLES.var)} \)
  and \( \text{maxval} \text{(VALUES.val)} \geq \text{maxval} \text{(VARIABLES.var)} \)
  implies MAX_NVALUE (MAX, VARIABLES).

- **GLOBAL_CARDINALITY** (VARIABLES, VALUES)
  with \( \text{range} \text{(VALUES.val)} = \text{nval} \text{(VALUES.val)} \)
  and \( \text{minval} \text{(VALUES.val)} \leq \text{minval} \text{(VARIABLES.var)} \)
  and \( \text{maxval} \text{(VALUES.val)} \geq \text{maxval} \text{(VARIABLES.var)} \)
  implies MIN_R (MIN, RANK, VARIABLES).

- **GLOBAL_CARDINALITY** (VARIABLES, VALUES)
  with \( \text{range} \text{(VALUES.val)} = \text{nval} \text{(VALUES.val)} \)
  and \( \text{minval} \text{(VALUES.val)} \leq \text{minval} \text{(VARIABLES.var)} \)
  and \( \text{maxval} \text{(VALUES.val)} \geq \text{maxval} \text{(VARIABLES.var)} \)
  implies MIN_NVALUE (MIN, VARIABLES).

- **GLOBAL_CARDINALITY** (VARIABLES, VALUES)
  with \( \text{range} \text{(VALUES.val)} = \text{nval} \text{(VALUES.val)} \)
  and \( \text{minval} \text{(VALUES.val)} \leq \text{minval} \text{(VARIABLES.var)} \)
  and \( \text{maxval} \text{(VALUES.val)} \geq \text{maxval} \text{(VARIABLES.var)} \)
  implies RANGE_CTR (VARIABLES, CTR, R).
GLOBAL CARDINALITY

For all items of VALUES:

Arc input(s) VARIABLES
Arc generator \( \text{SELF} \rightarrow \text{collection}(\text{variables}) \)
Arc arity 1
Arc constraint(s) \( \text{variables}.\text{var} = \text{VALUES}.\text{val} \)
Graph property(ies) \( \text{NVERTEX} = \text{VALUES}.\text{nocurrence} \)

Graph model

Since we want to express one unary constraint for each value we use the “For all items of VALUES” iterator. Part (A) of Figure 5.378 shows the initial graphs associated with each value 3, 5 and 6 of the VALUES collection of the Example slot. Part (B) of Figure 5.378 shows the two corresponding final graphs respectively associated with values 3 and 6 that are both assigned to the variables of the VARIABLES collection (since value 5 is not assigned to any variable of the VARIABLES collection the final graph associated with value 5 is empty). Since we use the NVERTEX graph property, the vertices of the final graphs are stressed in bold.

Figure 5.378: Initial and final graph of the GLOBAL CARDINALITY constraint
Automaton

Figure 5.379 depicts the automaton associated with the \textsc{global\_cardinality} constraint. To each item of the collection \textsc{variables} corresponds a signature variable $S_i$ that is equal to 0. To each item of the collection \textsc{values} corresponds a signature variable $S_i + |\textsc{variables}|$ that is equal to 1.

\[
\begin{align*}
&\{C[1] \leftarrow 0\} \\
&s \rightarrow 0, & \{C[\text{var}_i] \leftarrow C[\text{var}_i] + 1\} \\
&1, & \{C[\text{val}_i] \leftarrow C[\text{val}_i] - \text{nooccurrence}_i\} \\
&t \rightarrow 1, & \{C[\text{val}_i] \leftarrow C[\text{val}_i] - \text{nooccurrence}_i\} \\
&\textbf{arithmetic}(C_i = 0)
\end{align*}
\]

Figure 5.379: Automaton of the \textsc{global\_cardinality} constraint

Quiz

**EXERCISE 1** (checking whether a ground instance holds or not)

A. Does the constraint
\[
\textsc{global\_cardinality}((2, 4, 2, 2), (0, 0, 1, 2, 3, 3, 0, 4))
\]
hold?

B. Does the constraint
\[
\textsc{global\_cardinality}((0, 0, 1, 1), (0, 2, 1, 2, 1, 3, 0, 4))
\]
hold?

C. Does the constraint
\[
\textsc{global\_cardinality}((2, 3, 4, 5), (0, 0, 1, 0, 2, 1, 3, 1, 4))
\]
hold?

*Hint: go back to the definition of \textsc{global\_cardinality}.

**EXERCISE 2** (finding all solutions)

Give all the solutions to the constraint:

\[
\begin{cases}
V_1 \in [1, 2], & V_2 \in [1, 2], & V_3 \in [1, 2], \\
V_4 \in [2, 3], & V_5 \in [3, 3], \\
O_1 \in [1, 2], & O_2 \in [2, 3], & O_3 \in [0, 1], \\
\text{val}_1 \in [1, 2], & \text{val}_2 \in [2, 3], & \text{val}_3 \in [0, 1] \\
\text{ occurrence}_1 \in [1, 2], & \text{ occurrence}_2 \in [2, 3], & \text{ occurrence}_3 \in [0, 1] \\
\end{cases}
\]

\[
\textsc{global\_cardinality}\left(\begin{pmatrix}
\text{val}_1 - 1 \\
\text{val}_2 - 2 \\
\text{val}_3 - 3
\end{pmatrix}, \begin{pmatrix}
\text{occurrence}_1 - O_1 \\
\text{occurrence}_2 - O_2 \\
\text{occurrence}_3 - O_3
\end{pmatrix}\right).
\]

*Hint: focus on the variables of the first argument (since the counting variables of the second argument are functionally determined by the first argument), and enumerate solutions in lexicographic order.
EXERCISE 3 (identifying infeasible values)

Identify all variable-value pairs \((V_i, val)\) (respectively \((O_i, val)\)) (with \(i \in [1, 5]\)), such that the following constraint has no solution when variable \(V_i\) (respectively \(O_i\)) is assigned value \(val\):

\[
\begin{align*}
V_1 &\in [2, 3], & V_2 &\in [1, 5], & V_3 &\in [3, 4], \\
V_4 &\in [1, 3], & V_5 &\in [1, 4], & O_1 &\in [1, 4], \\
O_2 &\in [0, 1], & O_3 &\in [0, 1], & O_4 &\in [1, 5], \\
O_5 &\in [1, 4], & & & & \langle V_1, V_2, V_3, V_4, V_5 \rangle,
\end{align*}
\]

\[
\begin{pmatrix}
\text{val} - 1 & \text{occurrence} - O_1, \\
\text{val} - 2 & \text{occurrence} - O_2, \\
\text{val} - 3 & \text{occurrence} - O_3, \\
\text{val} - 4 & \text{occurrence} - O_4, \\
\text{val} - 5 & \text{occurrence} - O_5
\end{pmatrix}.
\]

*aHint: first restrict the occurrence variables \(O_1, O_2, \ldots, O_5\), second restrict the decision variables \(V_1, V_2, \ldots, V_5\), third check that all remaining values occur in at least one solution.*
EXERCISE 4 (modelling a nurse assignment problem)*

Given a 24 hour period, you must schedule a pool of six nurses Bea, Lea, Leo, Lio, Lili and Tom to at least two and at most three morning shifts, to at least two and at most three afternoon shifts, to at least one night shift, while the other nurses are off-duty. In addition, due to past work, we have the following extra requirements:

- Since on the previous 24 hour period Bea, Lea and Leo were working in the afternoon shift they cannot be assigned to the night shift.
- Leo, Lio and Lili have to work since they already took all their days off.
- Bea and Tom have to work together since Bea supervises Tom.

Provide a model of this problem that uses the `GLOBAL_CARDINALITY` constraint.

A. Provide a solution that satisfies all the constraints, i.e., for each nurse give his/her assignment (morning, afternoon, night, off-duty).

B. Identify the decision variables and the values of the problem, i.e., how do we model the fact that nurse $x \in \{\text{Bea, Lea, Leo, Lio, Lili, Tom}\}$ is assigned shift $y \in \{\text{morning, afternoon, night, off-duty}\}$?

C. Using a bipartite graph, draw the relations between the variables and the values identified in the previous question and display the solution you came up with in the first question.

D. Provide a model of the problem that uses a single `GLOBAL_CARDINALITY` constraint.

- Explain how the minimum/maximum capacity constraints (i.e., at least/at most) are modelled.
- Explain how each extra requirement is modelled in your solution.

*Hint: focus on what is a variable and what is a value in your model, and how to model the capacity constraints with `GLOBAL_CARDINALITY`. 
SOLUTION TO EXERCISE 1

A. Yes, since within \( (2, 4, 2, 2, 1) \), values 0, 1, 2, 3 and 4 are respectively used zero, one, three, zero, and one times.

B. No, since within \( (0, 0, 1, 1) \), value 2 is not used one time.

C. Yes, since within \( (2, 3, 4, 5) \), value 0, 1, 2 and 3 are respectively used zero, zero, one, and one times. The presence of a 5 in the solution does not matter since value 5 is not mentioned in the values of the second argument of the \textsc{global\_cardinality} constraint.

SOLUTION TO EXERCISE 2

the six solutions

\[
\begin{align*}
\langle v_1, v_2, v_3, v_4, v_5 \rangle & \langle o_1, o_2, o_3 \rangle \\
1 & (\{1, 1, 2, 2, 3\}, \{1 2 2 2 3 1\}) \\
2 & (\{1, 2, 1, 2, 3\}, \{1 2 2 2 3 1\}) \\
3 & (\{1, 2, 2, 2, 3\}, \{1 1 2 3 3 1\}) \\
4 & (\{2, 1, 1, 2, 3\}, \{1 2 2 2 3 1\}) \\
5 & (\{2, 1, 2, 2, 3\}, \{1 1 2 3 3 1\}) \\
6 & (\{2, 2, 1, 2, 3\}, \{1 1 2 3 3 1\})
\end{align*}
\]
SOLUTION TO EXERCISE 3

As suggested by the hint we go through the following steps:

A. [RESTRICTING THE OCCURRENCE VARIABLES $O_1, O_2, \ldots, O_5$]

(a) [PRUNING WRT THE MAXIMUM NUMBER OF OCCURRENCES OF EACH VALUE]
Since values 1, 2, 3, 4 and 5 can respectively be assigned to at most 3, 4, 5, 3 and 1 decision variables (e.g., value 1 can only be assigned to $V_2$, $V_4$ and $V_5$) we have $O_1 \leq \min(3, 4)$, $O_2 \leq \min(4, 1)$, $O_3 \leq \min(5, 1)$, $O_4 \leq \min(3, 5)$, and $O_5 \leq \min(1, 4)$.

(b) [PRUNING WRT $\sum_{i=1}^{5} O_i = 5$ AND THE DOMAIN OF $V_1$]
Since we have five decision variables the sum of the occurrence variables is equal to five (i.e., $O_1 + O_2 + O_3 + O_4 + O_5 = 5$). Since values 2 or 3 have to be assigned to the decision variable $V_1$ we have $O_2 + O_3 \geq 1$. It follows that $O_1 + O_4 + O_5 \leq 4$. Since $O_1 \in [1, 3]$, $O_4 \in [1, 3]$ and $O_5 = 1$ we get $O_1 + O_4 \leq 3$ and consequently $O_1 \leq 2$ and $O_4 \leq 2$.

B. [RESTRICTING THE DECISION VARIABLES $V_1, V_2, \ldots, V_5$]
At the end of step A we obtain $O_1 \in [1, 2]$, $O_2 \in [0, 1]$, $O_3 \in [0, 1]$, $O_4 \in [1, 2]$, and $O_5 \in [1, 1]$. Since $O_5 = 1$ and since $V_2$ is the only decision variable that can be assigned value 5 we have $V_2 = 5$.
Consequently $V_1 \in [2, 3]$, $V_2 \in [5, 5]$, $V_3 \in [3, 4]$, $V_4 \in [1, 3]$, and $V_5 \in [1, 4]$.

C. [CHECKING FOR A SUPPORT]
To show that no value can be removed from the domain of the decision and occurrence variables we show that every value that is still in the domain of a variable is part of a solution.

(a) A solution with $O_1 = 2$ is $V_1 = 2$, $V_2 = 5$, $V_3 = 4$, $V_4 = 1$, $V_5 = 1$ and $O_2 = 1$, $O_3 = 0$, $O_4 = 1$, $O_5 = 1$.

(b) A solution with $O_4 = 2$ is $V_1 = 2$, $V_2 = 5$, $V_3 = 4$, $V_4 = 1$, $V_5 = 4$ and $O_1 = 1$, $O_2 = 1$, $O_3 = 0$, $O_4 = 2$, $O_5 = 1$.

(c) We now assume that $O_1 = O_2 = O_3 = O_4 = O_5 = 1$, i.e., all decision variables must be distinct. Without loss of generality we ignore $V_2$, which is fixed to 5. We provide a set of solutions where $V_1$, $V_3$, $V_4$ and $V_5$ can respectively be assigned to all the values of their domains:

i. $V_1 = 2$, $V_3 = 3$, $V_4 = 1$, $V_5 = 4$.

ii. $V_1 = 2$, $V_3 = 4$, $V_4 = 3$, $V_5 = 1$.

iii. $V_1 = 2$, $V_3 = 4$, $V_4 = 1$, $V_5 = 3$.

iv. $V_1 = 3$, $V_3 = 4$, $V_4 = 1$, $V_5 = 2$.

v. $V_1 = 3$, $V_3 = 4$, $V_4 = 2$, $V_5 = 1$. 
SOLUTION TO EXERCISE 4

A. A feasible solution is the following assignment
   \[
   \begin{align*}
   &\text{Bea} : \text{morning} & \text{Lea} : \text{morning} & \text{Leo} : \text{afternoon} \\
   &\text{Lio} : \text{afternoon} & \text{Lili} : \text{night} & \text{Tom} : \text{morning}
   \end{align*}
   \]
   since:
   \begin{itemize}
   \item the number of morning shifts is between 2 and 3,
   \item the number of afternoon shifts is between 2 and 3,
   \item the number of night shifts is at least 1,
   \item Bea, Lea and Leo are not assigned to a night shift,
   \item Leo, Lio and Lili work,
   \item Bea and Tom are both assigned the same shift.
   \end{itemize}

B. To each nurse corresponds a variable whose initial domain is set to the types of shifts that nurse can actually perform (i.e., each shift type is encoded by a unique integer value).

C. The next figure provides a graphical representation of the assignment problem. To each nurse and to each shift type corresponds a vertex. There is an edge between a given nurse and a given shift type if and only if that nurse can perform that shift type. The solution given to question A is displayed with thick blue lines. The interval on top or below each vertex indicates the minimum and maximum number of edges that can reach the corresponding vertex in any solution; values in blue correspond to the number of edges of the displayed solution.

D. We get the following model
   \[
   \begin{align*}
   &M = 1, & A = 2, & N = 3, & O = 4, \\
   &\text{Bea} \in [M, O], & \text{Lea} \in [M, O], & \text{Leo} \in [M, O], \\
   &\text{Lio} \in [M, O], & \text{Lili} \in [M, O], & \text{Tom} \in [M, O], \\
   &O_M \in [2, 3], & O_A \in [2, 3], & O_N \in [1, 6], & O_O \in [0, 6], \\
   &\text{Bea} \neq N, & \text{Lea} \neq N, & \text{Leo} \neq N, \\
   &\text{Leo} \neq O, & \text{Lio} \neq O, & \text{Lili} \neq O, \\
   &\text{Bea} = \text{Tom},
   \end{align*}
   \]
   where:
   \begin{itemize}
   \item line 1 declares the integer value of each shift type,
   \item lines 2, 3 and 4 declare the nurse and occurrence variables,
   \item line 5 enforces Bea, Lea and Leo not to work on a night shift,
   \item line 6 imposes Leo, Lio and Lili to work,
   \item line 7 constrains Bea and Tom to work on the same shift,
   \item line 8 restricts each shift type to occur within a given range.
   \end{itemize}
5.166  GLOBAL_CARDINALITY_LOW_UP

Origin  
Used for defining SLIDING DISTRIBUTION.

Constraint  
GLOBAL_CARDINALITY_LOW_UP(VARIABLES, VALUES)

Synonyms  
GCC_LOW_UP, GCC.

Arguments  
VARIABLES : collection(var−dvar)  
VALUES : collection(val−int, omin−int, omax−int)

Restrictions  
required(VARIABLES, var)  
VALUES > 0  
required(VARIABLES, values)  
distinct(VARIABLES, val)  
VALUES.omin ≥ 0  
VALUES.omax ≤ |VARIABLES|  
VALUES.omin ≤ VALUES.omax

Purpose  
Each value VALUES[|i|].val (1 ≤ i ≤ |VALUES|) should be taken by at least VALUES[|i|].omin and at most VALUES[|i|].omax variables of the VARIABLES collection.

Example  
\[
\begin{bmatrix}
3, 3, 8, 6, \\
\text{val} = 3 & \text{omin} = 2 & \text{omax} = 3, \\
\text{val} = 5 & \text{omin} = 0 & \text{omax} = 1, \\
\text{val} = 6 & \text{omin} = 1 & \text{omax} = 2
\end{bmatrix}
\]

The GLOBAL_CARDINALITY_LOW_UP constraint holds since values 3, 5 and 6 are respectively used 2 (2 ≤ 2 ≤ 3), 0 (0 ≤ 0 ≤ 1) and 1 (1 ≤ 1 ≤ 2) times within the collection ⟨3, 3, 8, 6⟩ and since no constraint was specified for value 8.

Typical  
|VARIABLES| > 1  
\text{range}(VARIABLES.var) > 1  
|VALUES| > 1  
VALUES.omin ≤ |VARIABLES|  
VALUES.omax > 0  
VALUES.omax < |VARIABLES|  
|VARIABLES| > |VALUES|  
in_attr(VARIABLES.var, VALUES, val)
Symmetries

- Items of VARIABLES are permutable.
- An occurrence of a value of VARIABLES.var that does not belong to VALUES.val can be replaced by any other value that also does not belong to VALUES.val.
- Items of VALUES are permutable.
- VALUES.omin can be decreased to any value $\geq 0$.
- VALUES.omax can be increased to any value $\leq |VARIABLES|$.
- All occurrences of two distinct values in VARIABLES.var or VALUES.val can be swapped; all occurrences of a value in VARIABLES.var or VALUES.val can be renamed to any unused value.

Arg. properties

Contractible wrt. VALUES.

Remark

Within the context of linear programming [226, page 376] provides relaxations of the GLOBAL_CARDINALITY_LOW_UP constraint.

In MiniZinc (http://www.minizinc.org/) there is also a GLOBAL_CARDINALITY_LOW_UP_CLOSED constraint where all variables must be assigned a value from the val attribute.

Algorithm

A filtering algorithm achieving arc-consistency for the GLOBAL_CARDINALITY_LOW_UP constraint is given in [333]. This algorithm is based on a flow model of the GLOBAL_CARDINALITY_LOW_UP constraint where there is a one-to-one correspondence between feasible flows in the flow model and solutions to the GLOBAL_CARDINALITY_LOW_UP constraint. The leftmost part of Figure 3.30 illustrates this flow model.

The GLOBAL_CARDINALITY_LOW_UP constraint is entailed if and only if for each value $v$ equal to VALUES[i].val (with $1 \leq i \leq |VALUES|$) the following two conditions hold:

1. The number of variables of the VARIABLES collection assigned value $v$ is greater than or equal to VALUES[i].omin.
2. The number of variables of the VARIABLES collection that can potentially be assigned value $v$ is less than or equal to VALUES[i].omax.

Reformulation

A reformulation of the GLOBAL_CARDINALITY_LOW_UP, involving linear constraints, preserving bound-consistency was introduced in [78]. For each potential interval $[l, u]$ of consecutive values this model uses $|VARIABLES|$ 0-1 variables $B_1,l,u, B_2,l,u, \ldots, B_{|VARIABLES|},l,u$ for modelling the fact that each variable of the collection VARIABLES is assigned a value within interval $[l, u]$ (i.e., $\forall i \in [1, |VARIABLES|] : B_i,l,u \Leftrightarrow l \leq VARIABLES[i].var \land VARIABLES[i].var \leq u$), as well as one domain variable $C_{l,u}$ for counting how many values of $[l, u]$ are assigned to variables of VARIABLES (i.e. $C_{l,u} = B_{1,l,u} + B_{2,l,u} + \cdots + B_{|VARIABLES|},l,u$). The lower and upper bounds of variable $C_{l,u}$ are respectively initially set with respect to the minimum and maximum number of possible occurrences of the values of interval $[l, u]$. Finally, assuming that $s$ is the smallest value that can be assigned to the variables of VARIABLES, the constraint $C_{s,u} = C_{s,k} + C_{k+1,u}$ is stated for each $k \in [s, u - 1]$.

Systems

GLOBAL_CARDINALITY in Choco, GLOBAL_CARDINALITY_LOW_UP in MiniZinc.

Used in

SLIDING_DISTRIBUTION.

<tr>
<td></td>
<td>( \text{NVERTEX} \geq \text{VALUES.omin} )</td>
</tr>
<tr>
<td></td>
<td>( \text{NVERTEX} \leq \text{VALUES.omax} )</td>
</tr>
</tbody>
</table>

**Graph model**

Since we want to express one unary constraint for each value we use the “For all items of \( \text{VALUES} \)” iterator. Part (A) of Figure 5.380 shows the initial graphs associated with each value 3, 5 and 6 of the \( \text{VALUES} \) collection of the \textbf{Example} slot. Part (B) of Figure 5.380 shows the two corresponding final graphs respectively associated with values 3 and 6 that are both assigned to the variables of the \( \text{VARIABLES} \) collection (since value 5 is not assigned to any variable of the \( \text{VARIABLES} \) collection the final graph associated with value 5 is empty). Since we use the \( \text{NVERTEX} \) graph property, the vertices of the final graphs are stressed in bold.

![Initial and final graph of the GLOBAL_CARDINALITY_LOW_UP constraint](image-url)
5.167  GLOBAL/Cardinality_LOW_UP_NO_LOOP

Origin
Derived from GLOBAL/Cardinality_LOW and TREE.

Constraint
GLOBAL/Cardinality_LOW_UP_NO_LOOP (MINLOOP, MAXLOOP, VARIABLES, VALUES)

Synonym
GCC_LOW_UP_NO_LOOP.

Arguments
MINLOOP : int
MAXLOOP : int
VARIABLES : collection(var-dvar)
VALUES : collection(val-int, omin-int, omax-int)

Restrictions
MINLOOP ≥ 0
MINLOOP ≤ MAXLOOP
MAXLOOP ≤ |VARIABLES|
required(VARIABLES, var)
|VALUES| > 0
required(VVALUES, [val, omin, omax])
distinct(VVALUES, val)
VALUES.omin ≥ 0
VALUES.omax ≤ |VARIABLES|
VALUES.omin ≤ VALUES.omax

VALUES[i].omin (1 ≤ i ≤ |VALUES|) is less than or equal to the number of variables VARIABLES[j].var (j ≠ i, 1 ≤ j ≤ |VARIABLES|) that are assigned value VALUES[i].val.

VALUES[i].omax (1 ≤ i ≤ |VALUES|) is greater than or equal to the number of variables VARIABLES[j].var (j ≠ i, 1 ≤ j ≤ |VARIABLES|) that are assigned value VALUES[i].val.

The number of assignments of the form VARIABLES[i].var = i (i ∈ [1, |VARIABLES|]) is greater than or equal to MINLOOP and less than or equal to MAXLOOP.

Example

\[
\begin{bmatrix}
1, 1, (1, 1, 8, 6),
\end{bmatrix}
\]

The GLOBAL/Cardinality_LOW_UP_NO_LOOP constraint holds since:

- Values 1, 5 and 6 are respectively assigned to the set of variables \{VARIABLES[2].var\} (i.e., omin = 1 ≤ 1 ≤ omax = 1), {} (i.e., omin = 0 ≤
0 ≤ omax = 0) and \{\text{VARIABLES}[i].\text{var}\} (i.e., omin = 1 ≤ i ≤ omax = 2). Note that, due to the definition of the constraint, the fact that \text{VARIABLES}[1].\text{var} is assigned to 1 is not counted.

- In addition the number of assignments of the form \text{VARIABLES}[i].\text{var} = i (i ∈ [1, 4]) is greater than or equal to \text{MINLOOP} = 1 and less than or equal to \text{MAXLOOP} = 1.

**Typical**

| VARIABLES| > 1  
|----------|-----|  
| range\(\text{VARIABLES}.\text{var}\) > 1  
| VALUES| > 1  
| VALUES.\text{omin} ≤ |VARIABLES|  
| VALUES.\text{omax} > 0  
| VALUES.\text{omax} < |VARIABLES|  
| |VARIABLES| > |VALUES|

**Symmetries**

- Items of VALUES are permutable.
- VALUES.\text{omin} can be decreased to any value ≥ 0.
- VALUES.\text{omax} can be increased to any value ≤ |VARIABLES|.

**Usage**

Within the context of the \text{TREE} constraint the GLOBAL\_CARDINALITY\_LOW\_UP\_NO\_LOOP constraint allows one to model a minimum and maximum degree constraint on each vertex of our trees.

**Algorithm**

The flow algorithm that handles the original GLOBAL\_CARDINALITY constraint [353] can be adapted to the context of the GLOBAL\_CARDINALITY\_LOW\_UP\_NO\_LOOP constraint. This is done by creating an extra value node representing the loops corresponding to the roots of the trees. The rightmost part of Figure 3.30 illustrates the corresponding flow model for the GLOBAL\_CARDINALITY\_LOW\_UP\_NO\_LOOP constraint where there is a one-to-one correspondence between feasible flows in the flow model and solutions to the GLOBAL\_CARDINALITY\_LOW\_UP\_NO\_LOOP constraint.

**See also**

- generalisation: GLOBAL\_CARDINALITY\_NO\_LOOP (fixed interval replaced by variable).
- implied by: SAME\_AND\_GLOBAL\_CARDINALITY\_LOW\_UP.
- related: TREE (graph partitioning by a set of trees with degree restrictions).
- root concept: GLOBAL\_CARDINALITY\_LOW\_UP (assignment of a variable to its position is ignored).

**Keywords**

- constraint type: value constraint.
- filtering: flow.

</tr>
<tr>
<td>Graph property(ies)</td>
<td>NARC ≥ MINLOOP</td>
</tr>
<tr>
<td></td>
<td>NARC ≤ MAXLOOP</td>
</tr>
</tbody>
</table>

**Graph model**

Since, within the context of the first graph constraint, we want to express one unary constraint for each value we use the “For all items of VALUES” iterator. Part (A) of Figure 5.381 shows the initial graphs associated with each value 1, 5 and 6 of the VALUES collection of the Example slot. Part (B) of Figure 5.381 shows the two corresponding final graphs respectively associated with values 1 and 6 that are both assigned to the variables of the VARIABLES collection (since value 5 is not assigned to any variable of the VARIABLES collection the final graph associated with value 5 is empty). Since we use the NVERTEX graph property, the vertices of the final graphs are stressed in bold.

![Initial graphs](image)

![Final graphs](image)

Figure 5.381: Initial and final graph of the GLOBAL_CARDINALITY_LOW_UP_NO_LOOP constraint
5.168 GLOBAL_CARDINALITY_NO_LOOP

**Origin**
Derived from GLOBAL_CARDINALITY and TREE.

**Constraint**
GLOBAL_CARDINALITY_NO_LOOP(NLOOP, VARIABLES, VALUES)

**Synonym**
GCC_NO_LOOP.

**Arguments**
- NLOOP : dvar
- VARIABLES : collection(var−dvar)
- VALUES : collection(val−int,noccurrence−dvar)

**Restrictions**
- NLOOP ≥ 0
- NLOOP ≤ |VARIABLES|
- required(VARIABLES, var)
- |VALUES| > 0
- required(VALUES, [val, noccurrence])
- distinct(VALUES, val)
- VALUES.noccurrence ≥ 0
- VALUES.noccurrence ≤ |VARIABLES|

**Purpose**
VALUES[i].noccurrence (1 ≤ i ≤ |VALUES|) is equal to the number of variables VARIABLES[j].var (j ≠ i, 1 ≤ j ≤ |VARIABLES|) that are assigned value VALUES[i].val.

The number of assignments of the form VARIABLES[i].var = i (i ∈ [1, |VARIABLES|]) is equal to NLOOP.

**Example**

```
1, ⟨1, 1, 8, 6⟩ ,
( val − 1 noccurrence − 1,
val − 5 noccurrence − 0,
val − 6 noccurrence − 1)
```

The GLOBAL_CARDINALITY_NO_LOOP constraint holds since:
- Values 1, 5 and 6 are respectively assigned to the set of variables {VARIABLES[2].var} (i.e., 1 occurrence of value 1), { } (i.e., no occurrence of value 5) and {VARIABLES[4].var} (i.e., 1 occurrence of value 6). Note that, due to the definition of the constraint, the fact that VARIABLES[1].var is assigned to 1 is not counted.
- In addition the number of assignments of the form VARIABLES[i].var = i (i ∈ [1, 4]) is equal to NLOOP = 1.

**Typical**
- |VARIABLES| > 1
- range(VARIABLES.var) > 1
- |VALUES| > 1
- |VARIABLES| > |VALUES|
**Symmetry**  
Items of VALUES are permutable.

**Arg. properties**  
- *Functional dependency:* NLOOP determined by VARIABLES.
- *Functional dependency:* VALUES.nocurrence determined by VARIABLES and VALUES.val.

**Usage**  
Within the context of the TREE constraint the GLOBAL/Cardinality_NO_LOOP constraint allows one to model a minimum and maximum degree constraint on each vertex of our trees.

**Algorithm**  
The flow algorithm that handles the original GLOBAL/Cardinality constraint [353] can be adapted to the context of the GLOBAL/Cardinality_NO_LOOP constraint. This is done by creating an extra value node representing the loops corresponding to the roots of the trees.

**See also**

**Graph model**

Since, within the context of the first graph constraint, we want to express one unary constraint for each value we use the “For all items of VALUES” iterator. Part (A) of Figure 5.382 shows the initial graphs associated with each value 1, 5 and 6 of the VALUES collection of the Example slot. Part (B) of Figure 5.382 shows the two corresponding final graphs respectively associated with values 1 and 6 that are both assigned to the variables of the VARIABLES collection (since value 5 is not assigned to any variable of the VARIABLES collection the final graph associated with value 5 is empty). Since we use the NVERTEX graph property, the vertices of the final graphs are stressed in bold.

![Initial and final graph of the GLOBAL_CARDINALITY_NO_LOOP constraint](image-url)
5.169  GLOBAL_CARDINALITY_WITH_COSTS

Origin  [355]

Constraint  GLOBAL_CARDINALITY_WITH_COSTS(VARIABLES, VALUES, MATRIX, COST)

Synonyms  GCCC, COST_GCC.

Arguments  VARIABLES : collection(var−dvar)
VALUES : collection(val−int,noccurrence−dvar)
MATRIX : collection(i−int,j−int,c−int)
COST : dvar

Restrictions  
required(VARIABLES, var)
|VALUES| > 0
required(VALUES, [val,noccurrence])
distinct(VALUES, val)
VALUES.noccurrence ≥ 0
VALUES.noccurrence ≤ |VARIABLES|
required(MATRIX, [i,j,c])
increasing_seq(MATRIX, [i,j])
MATRIX.i ≥ 1
MATRIX.i ≤ |VARIABLES|
MATRIX.j ≥ 1
MATRIX.j ≤ |VALUES|
|MATRIX| = |VARIABLES| * |VALUES|

Purpose  
Each value VALUES[i].val should be taken by exactly VALUES[i].noccurrence variables of the VARIABLES collection. In addition the COST of an assignment is equal to the sum of the elementary costs associated with the fact that we assign variable i of the VARIABLES collection to the jth value of the VALUES collection. These elementary costs are given by the MATRIX collection.
Example

\[
\begin{pmatrix}
(3,3,3,6), \\
\{ \text{val} = 3 \ noccurrence = 3, \\
\text{val} = 5 \ noccurrence = 0, \\
\text{val} = 6 \ noccurrence = 1 \}
\end{pmatrix}, 14
\]

The \textsc{global_cardinality_with_costs} constraint holds since:

- Values 3, 5 and 6 respectively occur 3, 0 and 1 times within the collection \( (3,3,3,6) \).
- The \textsc{cost} argument corresponds to the sum of the costs respectively associated with the first, second, third and fourth items of \( (3,3,3,6) \), namely 4, 1, 3 and 6.

All solutions

Figure 5.383 gives all solutions to the following non ground instance of the \textsc{global_cardinality_with_costs} constraint:

\[
V_1 \in [3,4], V_2 \in [2,3], V_3 \in [1,2], V_4 \in [2,4], V_5 \in [2,3], V_6 \in [1,2], \\
O_1 \in [1,1], O_2 \in [2,3], O_3 \in [0,1], O_4 \in [2,3], \\
C \in [0,16], \\
\textsc{global_cardinality_with_costs}(V_1, V_2, V_3, V_4, V_5, V_6), \\
(1 \ O_1, 2 \ O_2, 3 \ O_3, 4 \ O_4), \\
(1 \ 15, 1 \ 20, 1 \ 31, 1 \ 41, \\
2 \ 12, 2 \ 27, 2 \ 30, 2 \ 42, \\
3 \ 13, 3 \ 23, 3 \ 36, 3 \ 46, \\
4 \ 14, 4 \ 23, 4 \ 30, 4 \ 40, \\
5 \ 12, 5 \ 20, 5 \ 36, 5 \ 43, \\
6 \ 15, 6 \ 24, 6 \ 35, 6 \ 44, C).
\]

Typical

| VARIABLES | > 1 |
| range(VARIABLES.var) | > 1 |
| VALUES | > 1 |
| range(VALUE.noccurrence) | > 1 |
| range(MATRIX.c) | > 1 |
| VARIABLES | > | VALUES |

Arg. properties

- Functional dependency: VALUES.noccurrence determined by VARIABLES.
- Functional dependency: COST determined by VARIABLES, VALUES and MATRIX.

Usage

A classical utilisation of the \textsc{global_cardinality_with_costs} constraint corresponds to the following assignment problem. We have a set of persons \( P \) as well as a set of jobs...
Figure 5.383: All solutions corresponding to the non-ground example of the \textsc{global\_cardinality\_with\_costs} constraint of the \textbf{All solutions} slot.

\[ \mathcal{J} \] to perform. Each job requires a number of persons restricted to a specified interval. In addition each person \( p \) has to be assigned to one specific job taken from a subset \( \mathcal{J}_p \) of \( \mathcal{J} \). There is a cost \( C_{pj} \) associated with the fact that person \( p \) is assigned to job \( j \). The previous problem is modelled with a single \textsc{global\_cardinality\_with\_costs} constraint where the persons and the jobs respectively correspond to the items of the \textsc{variables} and \textsc{values} collection.

The \textsc{global\_cardinality\_with\_costs} constraint can also be used for modelling a conjunction \textsc{all\_different}(\( x_1, x_2, \ldots, x_n \)) and \( \alpha_1 \cdot x_1 + \alpha_2 \cdot x_2 + \cdots + \alpha_n \cdot x_n = \text{cost} \).

For this purpose we set the domain of the \textsc{n\_occurrence} variables to \{0, 1\} and the cost attribute \( c \) of a variable \( x_i \) and one of its potential value \( j \) to \( \alpha_i \cdot j \). In practice this can be used for the \textsc{magic\ squares} and the \textsc{magic\ hexagon} problems where all the \( \alpha_i \) are set to 1.

\textbf{Algorithm}

A filtering algorithm achieving \textit{arc-consistency} independently on each side (i.e., the greater than or equal to side and the less than or equal to side) of the \textsc{global\_cardinality\_with\_costs} constraint is described in \[355, 357\]. This algorithm assumes for each value a fixed minimum and maximum number of occurrences. If we rather have occurrence variables, the \textbf{Reformulation slot} explains how to also obtain some propagation from the cost variable back to the occurrence variables.

\textbf{Reformulation}

Let \( n \) and \( m \) respectively denote the number of items of the \textsc{variables} and of the \textsc{values} collections. Let \( v_1, v_2, \ldots, v_m \) denote the values \textsc{values[1].val}, \textsc{values[2].val}, \ldots, \textsc{values[m].val}. In addition let \textsc{line}_i \ (\text{with} \ i \in [1, n]) \ denote the values \textsc{matrix}[m \cdot (i - 1) + 1].c, \textsc{matrix}[m \cdot (i - 1) + 2].c, \ldots, \textsc{matrix}[m \cdot i].c, \) i.e., line \( i \) of the matrix \textsc{matrix}.

By introducing \( 2 \cdot n \) auxiliary variables \( U_1, U_2, \ldots, U_n \) and \( C_1, C_2, \ldots, C_n \), the \textsc{global\_cardinality\_with\_costs}(\textsc{variables}, \textsc{values}, \textsc{matrix}, \textsc{cost}) constraint can be expressed in term of the conjunction of one \textsc{global\_cardinality}(\textsc{variables}, \textsc{values}) constraint, \( 2 \cdot n \) \textsc{element} constraints and one arithmetic constraint \textsc{sum\_ctr}. 
For each variable $V_i$ (with $i \in [1, |\text{VARIABLES}|]$) of the \text{VARIABLES} collection a first \text{ELEMENT}($U_i, \langle v_1, v_2, \ldots, v_m \rangle, V_i$) constraint provides the correspondence between the variable $V_i$ and the index of the value $U_i$ to which it is assigned. A second \text{ELEMENT}($U_i, \text{LINE}_i, C_i$) links the previous index $U_i$ to the cost $C_i$ variable associated with variable $V_i$. Finally the total cost $\text{COST}$ is equal to the sum $C_1 + C_2 + \cdots + C_n$.

In the context of the \textbf{Example} slot we get the following conjunction of constraints:

\textsc{global-cardinality}((3, 3, 3, 6),
\begin{align*}
\langle \text{val} = 3 \text{noccurrence} = 3, \\
\text{val} = 5 \text{noccurrence} = 0, \\
\text{val} = 6 \text{noccurrence} = 1 \rangle,
\end{align*}
\text{ELEMENT}(1, (3, 5, 6), 3),
\text{ELEMENT}(1, (3, 5, 6), 3),
\text{ELEMENT}(3, (3, 5, 6), 3),
\text{ELEMENT}(1, (4, 1, 7), 4),
\text{ELEMENT}(1, (1, 0, 8), 1),
\text{ELEMENT}(1, (3, 2, 1), 3),
\text{ELEMENT}(3, (0, 0, 6), 6),
14 = 4 + 1 + 3 + 6.

We now show how to add implied constraints that can also propagate from the cost variable back to the occurrence variables. Let $O_1, O_2, \ldots, O_m$ respectively denote the variables \text{VALUES}[1].\text{noccurrence}, \text{VALUES}[2].\text{noccurrence}, \ldots, \text{VALUES}[m].\text{noccurrence}. The idea is to get for each value $v_i$ (with $i \in [1, m]$) an idea of its minimum and maximum contribution in the total cost $\text{COST}$ that is linked to the number of times it is assigned to a variables \text{VARIABLES}. E.g., if value $v_i$ (with $i \in [1, m]$) is used twice, then the corresponding minimum (respectively maximum) contribution in the total cost $\text{COST}$ will be at least equal to the sum of the two smallest (respectively largest) costs attached to row $i$. Let $D_i$ (with $i \in [1, m]$) denotes the contribution that stems from the variables \text{VARIABLES} that are assigned value $v_i$. For each value $v_i$ (with $i \in [1, m]$) we create one \text{ELEMENT} constraint for linking $O_i + 1$ to the corresponding minimum contribution $\text{LOW}_i$. The table of that \text{ELEMENT} constraint has $n + 1$ entries, where entry $j$ (with $j \in [0, n]$) corresponds to the sum of the $j^{th}$ smallest entries of row $i$ of the cost matrix $\text{MATRIX}$. Similarly we create for each value $v_i$ (with $i \in [1, m]$) one \text{ELEMENT} constraint for linking $O_i + 1$ to the corresponding maximum contribution $\text{UP}_i$. The table of that \text{ELEMENT} constraint also has $n + 1$ entries, where entry $j$ (with $j \in [0, n]$) corresponds to the sum of the $j^{th}$ largest entries of row $i$ of the cost matrix $\text{MATRIX}$.

In the context of the cost matrix of the \textbf{Example} slot we get the following conjunction of implied constraints:

\begin{align*}
\text{COST} &= D_1 + D_2 + D_3, \\
n &= O_1 + O_2 + O_3, \\
P_1 &= O_1 + 1, \\
P_2 &= O_2 + 1, \\
P_3 &= O_3 + 1, \\
\text{ELEMENT}(P_1, (0, 0, 1, 4, 8), \text{LOW}_1), \\
\text{ELEMENT}(P_2, (0, 0, 0, 1, 3), \text{LOW}_2), \\
\text{ELEMENT}(P_3, (0, 1, 7, 14, 22), \text{LOW}_3), \\
\text{ELEMENT}(P_1, (0, 4, 7, 8, 1), \text{UP}_1),
\end{align*}
GLOBAL_CARDINALITY_WITH_COSTS

\[
\begin{align*}
\text{ELEMENT}(P_2; \{0, 2, 3, 3\}, UP_2), \\
\text{ELEMENT}(P_3; \{0, 8, 15, 21, 22\}, UP_3), \\
\text{LOW}_1 \leq D_1, D_1 \leq \text{UP}_1, \\
\text{LOW}_2 \leq D_2, D_2 \leq \text{UP}_2, \\
\text{LOW}_3 \leq D_3, D_3 \leq \text{UP}_3.
\end{align*}
\]

</tbody>
</table>

**Graph model**

The first graph constraint forces each value of the VALUES collection to be taken by a specific number of variables of the VARIABLES collection. It is identical to the graph constraint used in the GLOBAL_CARDINALITY constraint. The second graph constraint expresses that the COST variable is equal to the sum of the elementary costs associated with each variable-value assignment. All these elementary costs are recorded in the MATRIX collection. More precisely, the cost $c_{ij}$ is recorded in the attribute $c$ of the $((i - 1) \cdot |VALUES| + j)^{th}$ entry of the MATRIX collection. This is ensured by the increasing restriction that enforces the fact that the items of the MATRIX collection are sorted in lexicographically increasing order according to attributes $i$ and $j$.

Parts (A) and (B) of Figure 5.384 respectively show the initial and final graph associated with the second graph constraint of the **Example** slot.

GLOBAL_CARDINALITY_WITH_COSTS 1337
5.170  GLOBAL_CONTIGUITY

Origin  [282]

Constraint  GLOBAL_CONTIGUITY(VARIABLES)

Synonym  CONTIGUITY.

Argument  VARIABLES : collection(var–dvar)

Restrictions
  \[
  \text{required}(\text{VARIABLES}.\text{var})
  \]

  VARIABLES.var \geq 0

  VARIABLES.var \leq 1

Purpose  Enforce all variables of the VARIABLES collection to be assigned value 0 or 1. In addition, all variables assigned to value 1 appear contiguously.

Example

\[
\begin{align*}
\text{(0, 1, 1, 0)}
\end{align*}
\]

The GLOBAL_CONTIGUITY constraint holds since the sequence 0 1 1 0 contains no more than one group of contiguous 1.

All solutions

Figure 5.385 gives all solutions to the following non ground instance of the GLOBAL_CONTIGUITY constraint: \( V_1 \in [0, 1], V_2 \in [0, 1], V_3 = 1, V_4 \in [0, 1], \)

\[
\text{GLOBAL_CONTIGUITY}((V_1, V_2, V_3, V_4)).
\]

\begin{align*}
\& ((0, 0, 1, 0)) \\
\& ((0, 0, 1, 1)) \\
\& ((0, 1, 1, 0)) \\
\& ((0, 1, 1, 1)) \\
\& ((1, 1, 1, 0)) \\
\& ((1, 1, 1, 1))
\end{align*}

Figure 5.385: All solutions corresponding to the non ground example of the GLOBAL_CONTIGUITY constraint of the All solutions slot

Typical  |VARIABLES| > 2

Typical model

\[
\text{range}(\text{VARIABLES}.\text{var}) > 1 \\
\text{ATLEAST}(2, \text{VARIABLES}, 1)
\]
Symmetry

Items of VARIABLES can be reversed.

Arg. properties

Contractible wrt. VARIABLES.

Usage

The article [282] introducing this constraint refers to hardware configuration problems.

Algorithm

A filtering algorithm for this constraint is described in [282].

Figure 5.387: Automaton of the GLOBAL_CONTIGUITY constraint

Figure 5.388: Hypergraph of the reformulation corresponding to the automaton of the GLOBAL_CONTIGUITY constraint
5.171 GOLOMB

Origin
Inspired by [207].

Constraint
GOLOMB(VARIABLES)

Argument
VARIABLES : collection(var-dvar)

Restrictions
required(VARIABLES.var)
VARIABLES.var ≥ 0
STRICTLY_INCREASING(VARIABLES)

Purpose
Given a strictly increasing sequence $X_1, X_2, \ldots, X_n$, enforce all differences $X_i - X_j$ between two variables $X_i$ and $X_j$ ($i > j$) to be distinct.

Example

Figure 5.389 gives a graphical interpretation of the solution given in the example in term of a graph: each vertex corresponds to a value of $\langle 0, 1, 4, 6 \rangle$, while each arc depicts a difference between two values. The GOLOMB constraint holds since one can note that these differences $1, 4, 6, 3, 5, 2$ are all-distinct.

Figure 5.389: Graphical representation of the solution $0, 1, 4, 6$ (differences are displayed in light red and are pairwise distinct).

Typical
$|VARIABLES| > 2$

Symmetry
One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties
Contractible wrt. VARIABLES.

Usage
This constraint refers to the Golomb ruler problem. We quote the definition from [391]: “A Golomb ruler is a set of integers (marks) $a_1 < \cdots < a_k$ such that all the differences $a_i - a_j$ ($i > j$) are distinct”.

Remark

Different constraints models for the Golomb ruler problem were presented in [404].

Algorithm

At a first glance, one could think that, because it looks so similar to the ALLDIFFERENT constraint, we could have a perfect polynomial filtering algorithm. However this is not true since one retrieves the same variable in different vertices of the graph. This leads to the fact that one has incompatible arcs in the bipartite graph (the two classes of vertices correspond to the pair of variables and to the fact that the difference between two pairs of variables takes a specific value). However one can still reuse a similar filtering algorithm as for the ALLDIFFERENT constraint, but this will not lead to perfect pruning.

Derived Collection

\[
\text{col}\left( \text{PAIRS-collection}(x-dvar,y-dvar),
\text{item}(x-VARIABLES.var,y-VARIABLES.var) \right)
\]

Arc input(s) PAIRS
Arc generator \( CLIQUE \rightarrow \text{collection}(pairs1,pairs2) \)
Arc arity 2
Arc constraint(s) \( pairs1.y - pairs1.x = pairs2.y - pairs2.x \)
Graph property(ies) \( \text{MAX_NSCC} \leq 1 \)

Graph model
When applied on the collection of items \( \langle \text{VAR1, VAR2, VAR3, VAR4} \rangle \), the generator of derived collection generates the following collection of items: \( \langle \text{VAR2 VAR1, VAR3 VAR1, VAR3 VAR2, VAR4 VAR1, VAR4 VAR2, VAR4 VAR3} \rangle \). Note that we use a binary arc constraint between two vertices and that this binary constraint involves four variables.

Parts (A) and (B) of Figure 5.390 respectively show the initial and final graph associated with the Example slot. Since we use the \( \text{MAX_NSCC} \) graph property we show one of the largest strongly connected components of the final graph. The constraint holds since all the strongly connected components have at most one vertex: the differences \( 1, 2, 3, 4, 5, 6 \) that one can construct from the values \( 0, 1, 4, 6 \) assigned to the variables of the \( \text{VARIABLES} \) collection are all-distinct.

![Figure 5.390: Initial and final graph of the GOLOMB constraint](image)
## 5.172 GRAPH_CROSSING

**Origin**  
N. Beldiceanu

**Constraint**  
GRAPH_CROSSING(NCROSS, NODES)

**Synonyms**  
CROSSING, NCROSS.

**Arguments**  
NCROSS : dvar  
NODES : collection(succ - dvar, x - int, y - int)

**Restrictions**  
NCROSS ≥ 0  
required(NODES, [succ, x, y])  
NODES.succ ≥ 1  
NODES.succ ≤ |NODES|

**Purpose**  
NCROSS is the number of proper intersections between line segments, where each line segment is an arc of the directed graph defined by the arc linking a node and its unique successor.

**Example**  
\[
\begin{pmatrix}
\text{succ} - 1 & x - 4 & y - 7, \\
\text{succ} - 1 & x - 2 & y - 5, \\
\text{succ} - 1 & x - 7 & y - 6, \\
\text{succ} - 2 & x - 1 & y - 2, \\
\text{succ} - 3 & x - 2 & y - 2, \\
\text{succ} - 2 & x - 5 & y - 3, \\
\text{succ} - 3 & x - 8 & y - 2, \\
\text{succ} - 9 & x - 6 & y - 2, \\
\text{succ} - 10 & x - 10 & y - 6, \\
\text{succ} - 8 & x - 10 & y - 1
\end{pmatrix}
\]

Figure 5.391 shows the line segments associated with the NODES collection. One can note the following line segments intersection:

- Arcs 8 → 9 and 7 → 3 cross,
- Arcs 5 → 3 and 6 → 2 cross also.

Consequently, the GRAPH_CROSSING constraint holds since its first argument NCROSS is set to 2.

**Typical**  
|NODES| > 1  
range(NODES.succ) > 1  
range(NODES.x) > 1  
range(NODES.y) > 1
Symmetries

- Attributes of NODES are permutable w.r.t. permutation \((\text{succ} \ (x, y))\) \((\text{permutation applied to all items})\).
- One and the same constant can be added to the \(x\) attribute of all items of NODES.
- One and the same constant can be added to the \(y\) attribute of all items of NODES.

Arg. properties

Functional dependency: \(\text{NCROSS}\) determined by NODES.

Usage

This is a general crossing constraint that can be used in conjunction with one graph covering constraint such as CYCLE, TREE or MAP. In many practical problems ones want not only to cover a graph with specific patterns but also to avoid too much crossing between the arcs of the final graph.

Remark

We did not give a specific crossing constraint for each graph covering constraint. We feel that it is better to start first with a more general constraint before going in the specificity of the pattern that is used for covering the graph.

See also

- common keyword: CROSSING \((\text{line segments intersection})\).

\prod \left(\frac{n_2.y - n_1.y}{n_2.x - n_1.x,} - \right) & \neq \prod \left(\frac{n_2.x - n_1.x,}{\text{NODES}[n_2.succ].y - \text{NODES}[n_1.succ].y} \right) \\
\end{align*}
\]

### Graph property(ies)

\[ \text{NARC} = \text{NCROSS} \]

### Graph model

Each node is described by its coordinates \(x\) and \(y\), and by its successor \(\text{succ}\) in the final covering. Note that the co-ordinates are initially fixed. We use the arc generator \(\text{CLIQUE}(\langle \rangle)\) in order to avoid counting twice the same line segment crossing.

Parts (A) and (B) of Figure 5.392 respectively show the initial and final graph associated with the **Example** slot. Since we use the \(\text{NARC}\) graph property, the arcs of the final graph are stressed in bold. Each arc of the final graph corresponds to a proper intersection between two line segments.
Figure 5.392: Initial and final graph of the GRAPH\_CROSSING constraint
5.173 GRAPH ISOMORPHISM

DESCRIPTION

Origin [288]

Constraint

GRAPH ISOMORPHISM(NODES_PATTERN, NODES_TARGET, FUNCTION)

Arguments

NODES_PATTERN : collection(index-int, succ-sint)
NODES_TARGET : collection(index-int, succ-sint)
FUNCTION : collection(image-dvar)

Restrictions

required(NODES_PATTERN, [index, succ])
NODES_PATTERN.index ≥ 1
NODES_PATTERN.index ≤ |NODES_PATTERN|
distinct(NODES_PATTERN, index)
NODES_PATTERN.succ ≥ 1
NODES_PATTERN.succ ≤ |NODES_PATTERN|
required(NODES_TARGET, [index, succ])
NODES_TARGET.index ≥ 1
NODES_TARGET.index ≤ |NODES_TARGET|
distinct(NODES_TARGET, index)
NODES_TARGET.succ ≥ 1
NODES_TARGET.succ ≤ |NODES_TARGET|
|NODES_TARGET| = |NODES_PATTERN|
required(FUNCTION, [image])
FUNCTION.image ≥ 1
FUNCTION.image ≤ |NODES_TARGET|
distinct(FUNCTION, image)
|FUNCTION| = |NODES_PATTERN|

Purpose

Given two directed graphs PATTERN and TARGET enforce a one to one correspondence, defined by the function FUNCTION, between the vertices of the graph PATTERN and the vertices of the graph TARGET so that:

1. if there is an arc from u to v in the graph PATTERN, then there is also an arc from the image of u to the image of v in the graph TARGET,
2. if there is no arc from u to v in the graph PATTERN, then there is also no arc from the image of u to the image of v in the graph TARGET.

Both, the PATTERN and TARGET are fixed, and the vertices of both graphs are respectively defined by the two collections of vertices NODES_PATTERN and NODES_TARGET.
Figure 5.393 gives the pattern (see Part (A)) and target graph (see Part (B)) of the Example slot as well as the one to one correspondence (see Part (C)) between the pattern graph and the target graph. The GRAPH ISOMORPHISM constraint since the pattern and target graphs have the same number of vertices and arcs and since:

- To the arc from vertex 1 to vertex 4 in the pattern graph corresponds the arc from vertex 4 to 1 in the target graph.
- To the arc from vertex 1 to vertex 2 in the pattern graph corresponds the arc from vertex 4 to 2 in the target graph.
- To the arc from vertex 2 to vertex 1 in the pattern graph corresponds the arc from vertex 2 to 4 in the target graph.
- To the arc from vertex 2 to vertex 4 in the pattern graph corresponds the arc from vertex 2 to 1 in the target graph.
- To the arc from vertex 2 to vertex 3 in the pattern graph corresponds the arc from vertex 2 to 3 in the target graph.

Typical

| NODES_PATTERN | > 1 |

Symmetries

- Items of NODES_PATTERN are permutable.
- Items of NODES_TARGET are permutable.

Algorithm

A constraint approach is described in [406].

See also

related: SUBGRAPH ISOMORPHISM.

Keywords

- constraint arguments: constraint involving set variables.
- constraint type: predefined constraint, graph constraint.
Figure 5.393: Illustration of the Example slot: (A) The pattern graph, (B) the target graph and (C) the correspondence, denoted by thick dashed arcs, between the vertices of the pattern graph and the vertices of the target graph.
5.174 GROUP

Origin: CHIP

Constraint:

\[
\begin{pmatrix}
\text{NGROUP}, \\
\text{MIN\_SIZE}, \\
\text{MAX\_SIZE}, \\
\text{MIN\_DIST}, \\
\text{MAX\_DIST}, \\
\text{NVAL}, \\
\text{VARIABLES}, \\
\text{VALUES}
\end{pmatrix}
\]

Arguments:

- \text{NGROUP} : dvar
- \text{MIN\_SIZE} : dvar
- \text{MAX\_SIZE} : dvar
- \text{MIN\_DIST} : dvar
- \text{MAX\_DIST} : dvar
- \text{NVAL} : dvar
- \text{VARIABLES} : \text{collection}(\text{var} - \text{dvar})
- \text{VALUES} : \text{collection}(\text{val} - \text{int})

Restrictions:

- \text{NGROUP} \geq 0
- \text{MIN\_SIZE} \geq 0
- \text{MAX\_SIZE} \geq \text{MIN\_SIZE}
- \text{MIN\_DIST} \geq 0
- \text{MAX\_DIST} \geq \text{MIN\_DIST}
- \text{MAX\_DIST} \leq |\text{VARIABLES}|
- \text{NVAL} \geq \text{MAX\_SIZE}
- \text{NVAL} \geq \text{NGROUP}
- \text{NVAL} \leq |\text{VARIABLES}|
- \text{required}(\text{VARIABLES}, \text{var})
- \text{required}(\text{VALUES}, \text{val})
- \text{distinct}(\text{VALUES}, \text{val})
Let \( n \) be the number of variables of the collection \( \text{VARIABLES} \). Let \( X_i, X_{i+1}, \ldots, X_j \) (\( 1 \leq i \leq j \leq n \)) be consecutive variables of the collection of variables \( \text{VARIABLES} \) such that all the following conditions simultaneously apply:

- All variables \( X_i, \ldots, X_j \) take their values in the set of values \( \text{VALUES} \),
- \( i = 1 \) or \( X_{i-1} \) does not take a value in \( \text{VALUES} \),
- \( j = n \) or \( X_{j+1} \) does not take a value in \( \text{VALUES} \).

We call such a sequence of variables a group. Similarly an anti-group is a maximum sequence of variables that are not assigned any value from \( \text{VALUES} \). The constraint \( \text{GROUP} \) is true if all the following conditions hold:

- There are exactly \( \text{NGROUP} \) groups of variables,
- \( \text{MIN\_SIZE} \) is the number of variables of the smallest group,
- \( \text{MAX\_SIZE} \) is the number of variables of the largest group,
- \( \text{MIN\_DIST} \) is the number of variables of the smallest anti-group,
- \( \text{MAX\_DIST} \) is the number of variables of the largest anti-group,
- \( \text{NVAL} \) is the number of variables that take their values in the set of values \( \text{VALUES} \).

**Example**

\( (2, 1, 2, 4, 3, (2, 8, 1, 7, 4, 5, 1, 1, 1), (0, 2, 4, 6, 8)) \)

Given the fact that groups are formed by even values in \( \{0, 2, 4, 8\} \) (i.e., values expressed by the \( \text{VALUES} \) collection), the \( \text{GROUP} \) constraint holds since:

- Its first argument, \( \text{NGROUP} \), is set to value 2 since the sequence 2 8 1 7 4 5 1 1 1 contains two groups of even values (i.e., group 2 8 and group 4).
- Its second argument, \( \text{MIN\_SIZE} \), is set to value 1 since the smallest group of even values involves only a single value (i.e., value 4).
- Its third argument, \( \text{MAX\_SIZE} \), is set to value 2 since the largest group of even values involves two values (i.e., group 2 8).
- Its fourth argument, \( \text{MIN\_DIST} \), is set to value 2 since the smallest anti-group involves two values (i.e., anti-group 1 7).
- Its fifth argument, \( \text{MAX\_DIST} \), is set to value 4 since the largest anti-group involves four values (i.e., anti-group 5 1 1 1).
- Its sixth argument, \( \text{NVAL} \), is set to value 3 since the total number of even values of the sequence 2 8 1 7 4 5 1 1 1 is equal to 3 (i.e., values 2, 8 and 4).

**All solutions**

Figure 5.394 gives all solutions to the following non ground instance of the \( \text{GROUP} \) constraint: \( \text{NGROUP} \in [2, 3], \text{MIN\_SIZE} \in [3, 4], \text{MAX\_SIZE} \in [3, 5], \text{MIN\_DIST} \in [1, 2], \text{MAX\_DIST} \in [1, 2], \text{NVAL} \in [5, 6], \text{V}_1 \in [0, 1], \text{V}_2 \in [0, 1], \text{V}_3 \in [0, 1], \text{V}_4 \in [0, 1], \text{V}_5 \in [0, 1], \text{V}_6 \in [0, 1], \text{V}_7 \in [0, 1], \text{V}_8 \in [0, 1], \text{V}_9 \in [0, 1], \text{GROUP}(\text{NGROUP}, \text{MIN\_SIZE}, \text{MAX\_SIZE}, \text{MIN\_DIST}, \text{MAX\_DIST}, \text{NVAL}, \langle \text{V}_1, \text{V}_2, \text{V}_3, \text{V}_4, \text{V}_5, \text{V}_6, \text{V}_7, \text{V}_8, \text{V}_9 \rangle, (1)) \).
Figure 5.394: All solutions corresponding to the non ground example of the GROUP constraint of the All solutions slot

Typical

\[
\begin{align*}
\text{NGROUP} & > 0 \\
\text{MIN\_SIZE} & > 0 \\
\text{MAX\_SIZE} & > \text{MIN\_SIZE} \\
\text{MIN\_DIST} & > 0 \\
\text{MAX\_DIST} & > \text{MIN\_DIST} \\
\text{MAX\_DIST} & < |\text{VARIABLES}| \\
\text{NVAL} & > \text{MAX\_SIZE} \\
\text{NVAL} & > \text{NGROUP} \\
\text{NVAL} & < |\text{VARIABLES}| \\
|\text{VARIABLES}| & > 1 \\
\text{range}(\text{VARIABLES}.\text{var}) & > 1 \\
|\text{VALUES}| & > 0 \\
|\text{VARIABLES}| & > |\text{VALUES}| \\
\end{align*}
\]

Symmetries

- Items of \text{VARIABLES} can be reversed.
- Items of \text{VALUES} are permutable.
- An occurrence of a value of \text{VARIABLES}.\text{var} that belongs to \text{VALUES}.\text{val} (resp. does not belong to \text{VALUES}.\text{val}) can be replaced by any other value in \text{VALUES}.\text{val} (resp. not in \text{VALUES}.\text{val}).

Arg. properties

- Functional dependency: \text{NGROUP} determined by \text{VARIABLES} and \text{VALUES}.
- Functional dependency: \text{MIN\_SIZE} determined by \text{VARIABLES} and \text{VALUES}.
- Functional dependency: \text{MAX\_SIZE} determined by \text{VARIABLES} and \text{VALUES}.
- Functional dependency: \text{MIN\_DIST} determined by \text{VARIABLES} and \text{VALUES}.
- Functional dependency: \text{MAX\_DIST} determined by \text{VARIABLES} and \text{VALUES}.
- Functional dependency: \text{NVAL} determined by \text{VARIABLES} and \text{VALUES}.

Usage

A typical use of the GROUP constraint in the context of timetabling is as follow: The value of the \(i^{th}\) variable of the \text{VARIABLES} collection corresponds to the type of shift (i.e., night, morning, afternoon, rest) performed by a specific person on day \(i\). A complete period of work is represented by the variables of the \text{VARIABLES} collection. In this context the GROUP constraint expresses for a person:
- The number of periods of consecutive night-shift during a complete period of work.
- The total number of night-shift during a complete period of work.
- The maximum number of allowed consecutive night-shift.
- The minimum number of days, which do not correspond to a night-shift, between two consecutive sequences of night-shift.

**Remark**

For this constraint we use the possibility to express directly more than one constraint on the parameters of the final graph we want to obtain. For more propagation, it is crucial to keep this in a single constraint, since strong relations relate the different parameters of a graph. This constraint is very similar to the GROUP constraint introduced in CHIP, except that here, the MIN_DIST and MAX_DIST constraints apply also for the two borders: we cannot start or end with a group of $k$ consecutive variables that take their values outside VALUES and such that $k$ is less than MIN_DIST or $k$ is greater than MAX_DIST.

- **final graph structure:** connected component, vpartition, consecutive loops are connected.
- **modelling:** functional dependency.
We use two graph constraints for modelling the GROUP constraint: a first one for specifying the constraints on NGROUP, MIN_SIZE, MAX_SIZE and NVAL, and a second one for stating the constraints on MIN_DIST and MAX_DIST. In order to generate the initial graph related to the first graph constraint we use:

- The arc generators PATH and LOOP.
- The binary constraint variables1.var ∈ VALUES ∧ variables2.var ∈ VALUES.

On the first graph constraint of the Example slot this produces an initial graph depicted in part (A) of Figure 5.395. We use PATH LOOP and the binary constraint variables1.var ∈ VALUES ∧ variables2.var ∈ VALUES in order to catch the two following situations:

- A binary constraint has to be used in order to get the notion of group: Consecutive variables that take their values in VALUES.
- If we only use PATH then we would lose the groups that are composed from a single variable since the predecessor and the successor arc would be destroyed; this is why we use also the LOOP arc generator.

Part (B) of Figure 5.395 shows the final graph associated with the first graph constraint of the Example slot. Since we use the NVERTEX graph property, the vertices of the final graph are stressed in bold. In addition, since we use the MIN_NCC and the MAX_NCC graph properties, we also show the smallest and largest connected components of the final graph.

The GROUP constraint of the Example slot holds since:
Figure 5.395: Initial and final graph of the GROUP constraint
• The final graph of the first graph constraint has two connected components. Therefore the number of groups $\text{NGROUP}$ is equal to two.

• The number of vertices of the smallest connected component of the final graph of the first graph constraint is equal to 1. Therefore $\text{MIN\_SIZE}$ is equal to 1.

• The number of vertices of the largest connected component of the final graph of the first graph constraint is equal to 2. Therefore $\text{MAX\_SIZE}$ is equal to 2.

• The number of vertices of the smallest connected component of the final graph of the second graph constraint is equal to 2. Therefore $\text{MIN\_DIST}$ is equal to 2.

• The number of vertices of the largest connected component of the final graph of the second graph constraint is equal to 4. Therefore $\text{MAX\_DIST}$ is equal to 4.

• The number of vertices of the final graph of the first graph constraint is equal to three. Therefore $\text{NVAL}$ is equal to 3.
Figures 5.396, 5.398, 5.401, 5.403, 5.405 and 5.407 depict the different automata associated with the GROUP constraint. For the automata that respectively compute \( \text{NGROUP}, \text{MIN\_SIZE}, \text{MAX\_SIZE}, \text{MIN\_DIST}, \text{MAX\_DIST} \) and \( \text{NVAL} \) we have a 0-1 signature variable \( S_i \) for each variable \( \text{VAR}_i \) of the collection \( \text{VARIABLES} \). The following signature constraint links \( \text{VAR}_i \) and \( S_i \): \( \text{VAR}_i \in \text{VALUES} \Leftrightarrow S_i \).

5.175 **GROUP_SKIP_ISOLATED_ITEM**

**Origin**
Derived from `GROUP`.

**Constraint**

\[
\begin{pmatrix}
\text{NGROUP}, \\
\text{MIN\_SIZE}, \\
\text{MAX\_SIZE}, \\
\text{NVAL}, \\
\text{VARIABLES}, \\
\text{VALUES}
\end{pmatrix}
\]

**Arguments**

- `NGROUP`: dvar
- `MIN\_SIZE`: dvar
- `MAX\_SIZE`: dvar
- `NVAL`: dvar
- `VARIABLES`: `collection(var−dvar)`
- `VALUES`: `collection(val−int)`

**Restrictions**

- `NGROUP` ≥ 0
- `3 * NGROUP` ≤ `|VARIABLES|` + 1
- `MIN\_SIZE` ≥ 0
- `MIN\_SIZE` ≠ 1
- `MAX\_SIZE` ≥ `MIN\_SIZE`
- `NVAL` ≥ `MAX\_SIZE`
- `NVAL` ≥ `NGROUP`
- `NVAL` ≤ `|VARIABLES|`
- `required(VARIABLES, var)`
- `required(VALUES, val)`
- `distinct(VALUES, val)`

Let \( n \) be the number of variables of the collection `VARIABLES`. Let \( X_i, X_{i+1}, \ldots, X_j \) (\( 1 \leq i < j \leq n \)) be consecutive variables of the collection of variables `VARIABLES` such that the following conditions apply:

- All variables \( X_i, \ldots, X_j \) take their values in the set of values `VALUES`,
- \( i = 1 \) or \( X_{i−1} \) does not take a value in `VALUES`,
- \( j = n \) or \( X_{j+1} \) does not take a value in `VALUES`.

**Purpose**

We call such a set of variables a group. The constraint `GROUP_SKIP_ISOLATED_ITEM` is true if all the following conditions hold:

- There are exactly `NGROUP` groups of variables,
- The number of variables of the smallest group is `MIN\_SIZE`,
- The number of variables of the largest group is `MAX\_SIZE`,
- The number of variables that take their values in the set of values `VALUES` is equal to `NVAL`. 
Example

$\langle 1, 2, 2, 3, (2, 8, 1, 7, 4, 5, 1, 1, 1), (0, 2, 4, 6, 8) \rangle$

Given the fact that groups are formed by even values in $\{0, 2, 4, 6, 8\}$ (i.e., values expressed by the VALUES collection), and the fact that isolated even values are ignored, the GROUP.Skip.Isolated.Item constraint holds since:

- Its first argument, NGROUP, is set to value 1 since the sequence $2\,8\,1\,7\,4\,5\,1\,1\,1$ contains only one group of even values involving more than one even value (i.e., group $2\,8$).
- Its second and third arguments, MIN_SIZE and MAX_SIZE, are both set to 2 since the only group of even values with more than one even value involves two values (i.e., group $2\,8$).
- The fourth argument, NVAL, is fixed to 2 since it corresponds to the total number of even values belonging to groups involving more than one even value (i.e., value 4 is discarded since it is an isolated even value of the sequence $2\,8\,1\,7\,4\,5\,1\,1\,1$).

Typical

- NGROUP $> 0$
- MIN_SIZE $> 0$
- NVAL $> \text{MAX}_\text{SIZE}$
- NVAL $> \text{NGROUP}$
- NVAL $< |\text{VALUES}|$
- $|\text{VALUES}| > 1$
- range($\text{VALUES}.\text{var}$) $> 1$
- $|\text{VALUES}| > 0$
- $|\text{VALUES}| > |\text{VALUES}|$

Symmetries

- Items of VARIABLES can be reversed.
- Items of VALUES are permutable.
- An occurrence of a value of VARIABLES.var that belongs to VALUES.val (resp. does not belong to VALUES.val) can be replaced by any other value in VALUES.val (resp. not in VALUES.val).

Arg. properties

- Functional dependency: NGROUP determined by VARIABLES and VALUES.
- Functional dependency: MIN_SIZE determined by VARIABLES and VALUES.
- Functional dependency: MAX_SIZE determined by VARIABLES and VALUES.
- Functional dependency: NVAL determined by VARIABLES and VALUES.

Usage

This constraint is useful in order to specify rules about how rest days should be allocated to a person during a period of $n$ consecutive days. In this case VALUES are the codes for the rest days (perhaps a single value) and VARIABLES corresponds to the amount of work done during $n$ consecutive days. We can then express a rule like: in a month one should have at least 4 periods of at least 2 rest days (isolated rest days are not counted as rest periods).

Remark

The following invariant imposes a limit on the maximum number of groups wrt the minimum size of a group and the total number of variables: $\text{NGROUP} \cdot (\max(\text{MIN}_\text{SIZE}, 2) + 1) \leq |\text{VALUES}| + 1$.

• \text{MIN\_NSCC} = \text{MIN\_SIZE}
• \text{MAX\_NSCC} = \text{MAX\_SIZE}
• \text{NVERTEX} = \text{NVAL} |

**Graph model**

We use the $CHAIN$ arc generator in order to produce the initial graph. In the context of the Example slot, this creates the graph depicted in part (A) of Figure 5.409. We use $CHAIN$ together with the arc constraint $\text{variables1}.\text{var} \in \text{VALUES} \wedge \text{variables2}.\text{var} \in \text{VALUES}$ in order to skip the isolated variables that take a value in \text{VALUES} that we do not want to count as a group. This is why, on the example, value 4 is not counted as a group.

Part (B) of Figure 5.409 shows the final graph associated with the Example slot. The \text{GROUP\_SKIP\_ISOLATED\_ITEM} constraint of the Example slot holds since:

- The final graph contains one strongly connected component. Therefore the number of groups is equal to one.
- The unique strongly connected component of the final graph contains two vertices. Therefore \text{MIN\_SIZE} and \text{MAX\_SIZE} are both equal to 2.
- The number of vertices of the final graph is equal to two. Therefore \text{NVAL} is equal to 2.
Figure 5.409: Initial and final graph of the GROUP_SKIP_ISOLATED_ITEM constraint
Figures 5.410, 5.412, 5.414 and 5.416 depict the different automata associated with the GROUP_SKIP_ISOLATED_ITEM constraint. For the automata that respectively compute NGROUP, MIN_SIZE, MAX_SIZE and NVAL we have a 0-1 signature variable $S_i$ for each variable $VAR_i$ of the collection $VARIABLES$. The following signature constraint links $VAR_i$ and $S_i$: $VAR_i \in VALUES \iff S_i$.

Figure 5.410: Automaton for the NGROUP argument of the GROUP_SKIP_ISOLATED_ITEM constraint and its glue matrix, where counter $C$ is the number of groups encountered so far.

Figure 5.411: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the NGROUP argument of the GROUP_SKIP_ISOLATED_ITEM constraint (since all states of the automaton are accepting there is no restriction on the last variable $Q_n$).
The figure illustrates the automaton for the `MIN_SIZE` argument of the `GROUP_SKIP_ISOLATED_ITEM` constraint and its glue matrix. The counters \( C \) and \( D \) respectively correspond to the size of the smallest group encountered so far, and to the size of the current group.

The glue matrix shows transitions for states \( s \), \( t \), and \( r \) with inputs \((\varepsilon^*)\), \((\varepsilon^+)\), and \((\varepsilon^+)\) respectively:

- \( s \): not in `VALUES` mode
- \( t \), \( r \): in `VALUES` mode

The transitions are as follows:

- \( s \): not in `VALUES` mode
  - \((\varepsilon^*)\): \( C \leftarrow |\text{VARi\_VALUES}| \)
  - \((\varepsilon^+)\): \( D \leftarrow 0 \)

- \( t \), \( r \): in `VALUES` mode
  - \((\varepsilon^*)\): \( \text{not in} (\text{VARi\_VALUES}) \)
  - \((\varepsilon^+)\): \( \text{in} (\text{VARi\_VALUES}), \{ D \leftarrow 2 \} \)
  - \( \text{in} (\text{VARi\_VALUES}), \{ D \leftarrow D + 1 \} \)

The glue matrix represents the counters values \( C \) and \( D \) at the end of a prefix and at the end of the corresponding reverse suffix that partitions the sequence `VARi\_VALUES`.

The states and transitions are as follows:

- **States SEMANTICS**
  - \( s \) : not in `VALUES` mode
  - \( t \), \( r \) : in `VALUES` mode

- **Glue matrix**
  - \( s \): not in `VALUES` mode
  - \( t \), \( r \): in `VALUES` mode

- **Figure 5.412**: Automaton for the `MIN_SIZE` argument of the `GROUP_SKIP_ISOLATED_ITEM` constraint and its glue matrix; counters \( C \) and \( D \) respectively correspond to the size of the smallest group encountered so far, and to the size of the current group.
Figure 5.413: Hypergraph of the reformulation corresponding to the automaton (with two counters) of the MIN_SIZE argument of the GROUP_SKIP_ISOLATED_ITEM constraint (since all states of the automaton are accepting there is no restriction on the last variable $Q_n$.)
Figure 5.414: Automaton for the MAX_SIZE argument of the GROUP_SKIP_ISOLATED_ITEM constraint and its glue matrix; counters $C$ and $D$ respectively correspond to the size of the largest group encountered so far, and to the size of the current group.
Figure 5.415: Hypergraph of the reformulation corresponding to the automaton (with two counters) of the \texttt{MAX\_SIZE} argument of the \texttt{GROUP\_SKIP\_ISOLATED\_ITEM} constraint (since all states of the automaton are accepting there is no restriction on the last variable $Q_n$).

$\max(C_n, D_n) = C_n$  
$D_0 = 0$  
$C_0 = 0$  
$Q_0 = s$  
$C_1$  
$D_1$  
$S_1$

Figure 5.417: Hypergraph of the reformulation corresponding to the automaton (with one counter) of the \texttt{NVAL} argument of the \texttt{GROUP\_SKIP\_ISOLATED\_ITEM} constraint.
**5.176 GT**

**Origin**
Arithmetic.

**Constraint**
GT(VAR1, VAR2)

**Synonyms**
REL, XGTY.

**Arguments**
- VAR1: dvar
- VAR2: dvar

**Purpose**
Enforce the fact that the first variable is strictly greater than the second variable.

**Example**

\[(8, 1)\]

The GT constraint holds since 8 is strictly greater than 1.

**Symmetries**
- VAR1 can be replaced by any value > VAR2.
- VAR2 can be replaced by any value < VAR1.

**Systems**
- GT in Choco, REL in Gecode, XGTY in JaCoP, #> in SICStus.

**See also**
- common keyword: EQ (binary constraint, arithmetic constraint).
- implies: GEQ, NEQ.
- implies (if swap arguments): LT.
- negation: LEQ.

**Keywords**
- constraint arguments: binary constraint.
- constraint type: predefined constraint, arithmetic constraint.
- filtering: arc-consistency.
### 5.177 HIGHEST_PEAK

**Origin**
Derived from PEAK.

**Constraint**
HIGHEST_PEAK(HEIGHT, VARIABLES)

**Arguments**
- HEIGHT : dvar
- VARIABLES : collection(var – dvar)

**Restriction**
required(VARIABLES, var)

**Purpose**
A variable \(V_k\) \((1 < k < m)\) of the sequence of variables VARIABLES = \(V_1, \ldots, V_m\) is a peak if and only if there exists an \(i\) \((1 < i \leq k)\) such that \(V_{i-1} < V_i\) and \(V_i = V_{i+1} = \cdots = V_k\) and \(V_k > V_{k+1}\). HEIGHT is the maximum value of the peak variables. If no such variable exists, HEIGHT is equal to MININT.

**Example**
\((8, (1, 1, 4, 8, 6, 2, 7, 1))\)
\((1, (0, 1, 1, 0, 0, 1, 0, 1))\)

The first HIGHEST_PEAK constraint holds since 8 is the maximum peak of the sequence 1 1 4 8 6 2 7 1.

![Illustration of the first constraint of the Example slot](image)

Figure 5.418: Illustration of the first constraint of the Example slot: a sequence of eight variables \(V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8\) respectively fixed to values 1, 1, 4, 8, 6, 2, 7, 1 and its corresponding highest peak 8

**Typical**
- \(|\text{VARIABLES}| > 2\)
- range(VARIABLES.var) > 2
- PEAK(VARIABLES.var) > 0
Typical model: \( \text{nval(VARIABLES.var)} > 2 \)

Symmetry: Items of VARIABLES can be reversed.

Arg. properties: Functional dependency: HEIGHT determined by VARIABLES.

implies: BETWEEN\_MIN\_MAX.
### Keywords

- **characteristic of a constraint**: automaton, automaton with counters, automaton with same input symbol.
- **combinatorial object**: sequence.
- **constraint arguments**: reverse of a constraint, pure functional dependency.
- **constraint network structure**: sliding cyclic(1) constraint network(2).
- **filtering**: glue matrix.
- **modelling**: functional dependency.
Automaton

Figure 5.419 depicts the automaton associated with the HIGHEST_PEAK constraint. To each pair of consecutive variables (VAR\(_i\), VAR\(_{i+1}\)) of the collection VARIABLES corresponds a signature variable S\(_i\). The following signature constraint links VAR\(_i\), VAR\(_{i+1}\) and S\(_i\):

\[
\text{VAR}_i < \text{VAR}_{i+1} \iff S_i = 0 \land \text{VAR}_i = \text{VAR}_{i+1} \iff S_i = 1 \land \text{VAR}_i > \text{VAR}_{i+1} \iff S_i = 2.
\]

STATE SEMANTICS

\[s: \text{stationary/decreasing mode}, \quad u: \text{increasing mode}\]

Glue matrix where \(\overrightarrow{C}\) and \(\overleftarrow{C}\) resp. represent the counters values \(C\) at the end of a prefix and at the end of the corresponding reverse suffix that partitions the sequence VARIABLES; \(\overline{X}\) denotes the last variable of the prefix.

Figure 5.419: Automaton of the HIGHEST_PEAK constraint and its glue matrix (state \(s\) means that we are in decreasing or stationary mode, state \(u\) means that we are in increasing mode, a new peak is detected each time we switch from increasing to decreasing mode and the counter \(C\) is updated accordingly); minint is the smallest integer that can be represented on a machine.

Figure 5.420: Hypergraph of the reformulation corresponding to the automaton of the HIGHEST_PEAK constraint (\(C_0\) is set to minint the largest integer that can be represented on a machine).
5.178  IMPLY

DESCRIPTION  LINKS  AUTOMATON

Origin  Logic

Constraint  IMPLY(VAR, VARIABLES)

Synonyms  REL, IFTHEN.

Arguments

<table>

Derived Collection

col(VARIABLES −> collection(var − dvar)., item(var − VAR))

Arc input(s)
VARIABLES VALUES

Arc generator
PRODUCT -> collection(variables, values)

Arc arity
2

Arc constraint(s)
variables.var = values.val

Graph property(ies)
\textbf{NARC} = 1

Graph model
Parts (A) and (B) of Figure 5.423 respectively show the initial and final graph associated with the Example slot. Since we use the \textbf{NARC} graph property, the unique arc of the final graph is stressed in bold.

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{figure}
\caption{Initial and final graph of the IN constraint}
\end{figure}

Signature
Since all the \texttt{val} attributes of the VALUES collection are distinct and because of the arc constraint \texttt{variables.var = values.val} the final graph contains at most one arc. Therefore we can rewrite \textbf{NARC} = 1 to \textbf{NARC} \geq 1 and simplify \textbf{NARC} to \textbf{NARC}. 
Automaton

Figure 5.424 depicts the automaton associated with the IN constraint. Let VAL_i be the val attribute of the i^{th} item of the VALUES collection. To each pair (VAR, VAL_i) corresponds a 0-1 signature variable S_i as well as the following signature constraint: VAR = VAL_i ⇔ S_i.

Figure 5.424: Automaton of the IN constraint

Figure 5.425: Hypergraph of the reformulation corresponding to the automaton of the IN constraint
5.180 IN_INTERVAL

Origin: Domain definition.

Constraint: \( \text{IN}_\text{INTERVAL}(\text{VAR}, \text{LOW}, \text{UP}) \)

Synonyms: \( \text{DOM}, \text{IN}. \)

Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{VAR} )</td>
<td>dvar</td>
</tr>
<tr>
<td>( \text{LOW} )</td>
<td>int</td>
</tr>
<tr>
<td>( \text{UP} )</td>
<td>int</td>
</tr>
</tbody>
</table>

Restriction: \( \text{LOW} \leq \text{UP} \)

Purpose: Enforce the domain variable \( \text{VAR} \) to take a value within the interval \([\text{LOW}, \text{UP}]\).

Example: \((3, 2, 5)\)

The \(\text{IN}_\text{INTERVAL}\) constraint holds since its first argument \(\text{VAR} = 3\) is greater than or equal to its second argument \(\text{LOW} = 2\) and less than or equal to its third argument \(\text{UP} = 5\).

Typical:

<table>
<thead>
<tr>
<th>Typical</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{LOW} &lt; \text{UP} )</td>
<td></td>
</tr>
<tr>
<td>( \text{VAR} &gt; \text{LOW} )</td>
<td></td>
</tr>
<tr>
<td>( \text{VAR} &lt; \text{UP} )</td>
<td></td>
</tr>
</tbody>
</table>

Symmetries:

- \( \text{LOW} \) can be decreased.
- \( \text{UP} \) can be increased.
- An occurrence of a value of \( \text{VAR} \) can be replaced by any other value in \([\text{LOW}, \text{UP}]\).
- One and the same constant can be added to \( \text{VAR}, \text{LOW} \) and \( \text{UP} \).

Remark: Entailment occurs immediately after posting this constraint.

The \(\text{IN}_\text{INTERVAL}\) constraint is referenced under the name \(\text{DOM}\) in \textbf{Gecode}.

Systems: \(\text{MEMBER} \) in \textbf{Choco}, \(\text{DOM} \) in \textbf{Gecode}, \(\text{IN} \) in \textbf{JaCoP}, \(\text{IN} \) in \textbf{SICStus}.

See also: common keyword: \(\text{DOMAIN, IN (domain definition)}\).

generalisation: \(\text{IN}_\text{INTERVAL}\_\text{REIFIED} \) (reified version), \(\text{IN}_\text{INTERVALS} \) (single interval replaced by a set of intervals), \(\text{IN}_\text{SET} \) (interval replaced by set variable).
Keywords

\end{tikzpicture}
\end{center}

Figure 5.428: Hypergraph of the reformulation corresponding to the automaton of the \texttt{IN\_INTERVAL} constraint
5.181 IN_INTERVAL_REIFIED

DESCRIPT LINKS

Origin
Reified version of IN_INTERVAL.

Constraint
IN_INTERVAL_REIFIED(VAR, LOW, UP, B)

Synonyms
DOM_REIFIED, IN_REIFIED.

Arguments
VAR : dvar
LOW : int
UP : int
B : dvar

Restrictions
LOW ≤ UP
B ≥ 0
B ≤ 1

Purpose
Enforce the following equivalence, VAR ∈ [LOW, UP] ⇔ B.

Example

\[
(3, 2, 5, 1)
\]

The IN_INTERVAL_REIFIED constraint holds since:

- Its first argument VAR = 3 is greater than or equal to its second argument LOW = 2
  and less than or equal to its third argument UP = 5 (i.e., 3 ∈ [2, 5]).
- The corresponding Boolean variable B is set to 1 since condition 3 ∈ [2, 5] holds.

Typical
VAR ≠ LOW
VAR ≠ UP
LOW < UP

Symmetries
- An occurrence of a value of VAR that belongs to [LOW, UP] (resp. does not belong to
  [LOW, UP]) can be replaced by any other value in [LOW, UP]) (resp. not in [LOW, UP]).
- One and the same constant can be added to VAR, LOW and UP.

Reformulation
The IN_INTERVAL_REIFIED constraint can be reformulated in terms of linear constraints.
For convenience, we rename VAR to \(x\), LOW to \(l\), UP to \(u\), and B to \(y\). The constraint is
decomposed into the following conjunction of constraints:

\[
\begin{align*}
x & \geq l \iff y_1, \\
x & \leq u \iff y_2, \\
y_1 \land y_2 & \iff y.
\end{align*}
\]
We show how to encode these constraints with linear inequalities. The first constraint, i.e., \( x \geq l \iff y_1 \) is encoded by posting one of the following three constraints:

\[
\begin{cases}
  a) & \text{if } x \geq l : \quad y_1 = 1, \\
  b) & \text{if } x < l : \quad y_1 = 0, \\
  c) & \text{otherwise : } \quad x \geq (l-x) \cdot y_1 + x \land x \leq (x - l + 1) \cdot y_1 + l - 1.
\end{cases}
\]

On the one hand, cases a) and b) correspond to situations where one can fix \( y_1 \), no matter what value will be assigned to \( x \). On the other hand, in case c), \( y_1 \) can take both values 0 or 1 depending on the value assigned to \( x \). As shown by Figure 5.429, all possible solutions for the pair of variables \((x, y_1)\) satisfy the following two linear inequalities \( x \geq (l-x) \cdot y_1 + x \land x \leq (x - l + 1) \cdot y_1 + l - 1 \), while the second one removes all points that are below the line that goes through the two extreme solution points \((l, 0)\) and \((l, 1)\).

![Figure 5.429](image.png)

Figure 5.429: Illustration of the reformulation of the reified constraint \( x \geq l \iff y_1 \) with two linear inequalities

The second constraint, i.e., \( x \leq u \iff y_2 \) is encoded by posting one of the following three constraints:

\[
\begin{cases}
  d) & \text{if } x \leq u : \quad y_2 = 1, \\
  e) & \text{if } x > u : \quad y_2 = 0, \\
  f) & \text{otherwise : } \quad x \leq (u - x) \cdot y_2 + u \land x \geq (x - u - 1) \cdot y_2 + u + 1.
\end{cases}
\]

On the one hand, cases d) and e) correspond to situations where one can fix \( y_2 \), no matter what value will be assigned to \( x \). On the other hand, in case f), \( y_2 \) can take both value 0 or 1 depending on the value assigned to \( x \). As shown by Figure 5.430, all possible solutions for the pair of variables \((x, y_2)\) satisfy the following two linear inequalities \( x \leq (u - x) \cdot y_2 + u \land x \geq (x - u - 1) \cdot y_2 + u + 1 \). The first inequality discards all points that are above the line that goes through the two extreme solution points \((u, 0)\) and \((u, 1)\), while the second one removes all points that are above the line that goes through the two extreme solution points \((u + 1, 0)\) and \((x, 1)\).
The third constraint, i.e., \( y_1 \land y_2 \Leftrightarrow y \) is encoded as:

\[
\begin{cases}
  g) & y \geq y_1 + y_2 - 1, \\
  h) & y \leq y_1, \\
  i) & y \leq y_2.
\end{cases}
\]

Case g) handles the implication \( y_1 \land y_2 \Rightarrow y \), while cases h) and i) take care of the other side \( y \Rightarrow y_1 \land y_2 \).

See also specialisation: \texttt{IN\_INTERVAL}.

Uses in its reformulation: \texttt{ALLDIFFERENT} (bound consistency preserving reformulation).

Keywords characteristic of a constraint: reified constraint.

constraint arguments: binary constraint.

constraint type: predefined constraint, value constraint.

filtering: arc-consistency.

IN_INTERVALS
## 5.183 IN_RELATION

**Origin**
Constraint explicitly defined by tuples of values.

**Constraint**
\[
\text{IN\_RELATION}((\text{VARIABLES}, \text{TUPLES\_OF\_VALS}))
\]

**Synonyms**
CASE, EXTENSION, EXTENSIONAL, EXTENSIONAL\_SUPPORT, EXTENSIONAL\_SUPPORT\_VA, EXTENSIONAL\_SUPPORT\_MDD, EXTENSIONAL\_SUPPORT\_STR, FEASTUPLEAC, TABLE.

**Types**
- \text{TUPLE\_OF\_VARS} : \text{collection}(\text{var}−\text{dvar})
- \text{TUPLE\_OF\_VALS} : \text{collection}(\text{val}−\text{int})

**Arguments**
- \text{VARIABLES} : \text{TUPLE\_OF\_VARS}
- \text{TUPLES\_OF\_VALS} : \text{collection}(\text{tuple} − \text{TUPLE\_OF\_VALS})

**Restrictions**
- \text{required}(\text{TUPLE\_OF\_VARS}, \text{var})
- \(|\text{TUPLE\_OF\_VARS}| \geq 1\)
- \(|\text{TUPLE\_OF\_VALS}| \geq 1\)
- \(|\text{TUPLE\_OF\_VALS}| = |\text{VARIABLES}|\)
- \text{required}(\text{TUPLE\_OF\_VALS}, \text{val})
- \text{required}(\text{TUPLES\_OF\_VALS}, \text{tuple})

**Purpose**
Enforce the tuple of variables \text{VARIABLES} to take its value out of a set of tuples of values \text{TUPLES\_OF\_VALS}. The value of a tuple of variables \(\langle V_1, V_2, \ldots, V_n \rangle\) is a tuple of values \(\langle U_1, U_2, \ldots, U_n \rangle\) if and only if \(V_1 = U_1 \land V_2 = U_2 \land \cdots \land V_n = U_n\).

**Example**
\[
(\langle 5, 3, 3 \rangle, \langle \text{tuple} − \langle 5, 2, 3 \rangle, \text{tuple} − \langle 5, 2, 6 \rangle, \text{tuple} − \langle 5, 3, 3 \rangle \rangle)
\]
The \text{IN\_RELATION} constraint holds since its first argument \(\langle 5, 3, 3 \rangle\) corresponds to the third item of the collection of tuples \text{TUPLES\_OF\_VALS}.

**Typical**
\(|\text{TUPLE\_OF\_VARS}| > 1\)

**Symmetries**
- Items of \text{TUPLES\_OF\_VALS} are \text{permuta}ble.
- Items of \text{VARIABLES} and \text{TUPLES\_OF\_VALS}.\text{tuple} are \text{permuta}ble \text{same permutation used}.
- All occurrences of two distinct tuples of values in \text{VARIABLES} or \text{TUPLES\_OF\_VALS}.\text{tuple} can be \text{swapped}; all occurrences of a tuple of values in \text{VARIABLES} or \text{TUPLES\_OF\_VALS}.\text{tuple} can be \text{re}named to any unused tuple of values.
Arg. properties

| Extensible wrt. TUPLES_OF_VALS. |

Usage

Quite often some constraints cannot be easily expressed, neither by a formula, nor by a regular pattern. In this case one has to define the constraint by specifying in extension the combinations of allowed values.

Remark

The IN_RELATION constraint is called EXTENSIONAL_SUPPORT in JaCoP (http://www.jacop.eu/). Within SICStus Prolog the constraint can be applied to more than a single tuple of variables and is called TABLE. Within [92] this constraint is called EXTENSION.

The IN_RELATION constraint is called TABLE in MiniZinc (http://www.minizinc.org/).

Systems

Used in

COND_LEX_COST, COND_LEX_GREATER, COND_LEX_GREATEREQ, COND_LEX_LESS, COND_LEX_LESSEQ.

See also

- common keyword: ELEMENT (data constraint).
- cost variant: COND_LEX_COST (COST parameter added).
- used in graph description: VEC_EQ_TUPLE.

Graph model

Parts (A) and (B) of Figure 5.431 respectively show the initial and final graph associated with the Example slot. Since we use the \text{NARC} graph property, the unique arc of the final graph is stressed in bold.

Figure 5.431: Initial and final graph of the \text{IN_RELATION} constraint
5.184 IN_SAME_PARTITION

Origin
Used for defining several entries of this catalog.

Constraint
IN_SAME_PARTITION(VAR1, VAR2, PARTITIONS)

Type
VALUES : collection(val-int)

Arguments
VAR1 : dvar
VAR2 : dvar
PARTITIONS : collection(p - VALUES)

Restrictions
|VALUES| ≥ 1
required(VALUE, val)
distinct(VALUE, val)
required(PARTITIONS, p)
|PARTITIONS| ≥ 2

Purpose
Enforce VAR1 and VAR2 to be respectively assigned to values \(v_1\) and \(v_2\) that both belong to a same partition of the collection PARTITIONS.

Example
\((6, 2, \langle p - \langle 1, 3\rangle, p - \langle 4\rangle, p - \langle 2, 6\rangle\rangle)\)

The IN_SAME_PARTITION constraint holds since its first and second arguments VAR1 = 6 and VAR2 = 2 both belong to the third partition \(\langle 2, 6\rangle\) of its third argument PARTITIONS.

Typical
VAR1 ≠ VAR2

Symmetries
- Arguments are permutable w.r.t. permutation \((VAR1, VAR2)\) (PARTITIONS).
- Items of PARTITIONS are permutable.
- Items of PARTITIONS.p are permutable.

Arg, properties
Extensible wrt. PARTITIONS.

Used in
ALLDIFFERENT_PARTITION, BALANCE_PARTITION, CHANGE_PARTITION, COMMON_PARTITION, NCLASS, SAME_PARTITION, SOFT_SAME_PARTITION_VAR, SOFT_USED_BY_PARTITION_VAR, USED_BY_PARTITION.

See also
common keyword: ALLDIFFERENT_PARTITION (partition), IN (value constraint).
used in graph description: IN.
Keywords

characteristic of a constraint: partition, automaton, automaton without counters, reified automaton constraint, derived collection.

constraint arguments: binary constraint.

constraint network structure: centered cyclic(2) constraint network(1).

constraint type: value constraint.

filtering: arc-consistency.
Derived Collection

\[
\text{col}(\text{VARIABLES} - \text{collection}(\text{var} - \text{dvar}),\\ [\text{item} (\text{var} \rightarrow \text{VAR1}), \text{item} (\text{var} \rightarrow \text{VAR2})])
\]

Arc input(s) VARIABLES PARTITIONS
Arc generator \text{PRODUCT} \rightarrow \text{collection}(\text{variables}.\text{partitions})
Arc arity 2
Arc constraint(s) \text{IN} (\text{variables}.\text{var}, \text{partitions}.\text{p})
Graph property(ies)
- \text{NSOURCE} = 2
- \text{NSINK} = 1

Graph model

VAR1 and VAR2 are put together in the derived collection VARIABLES. Since both VAR1 and VAR2 should take their values in one of the partition depicted by the PARTITIONS collection, the final graph should have two sources corresponding respectively to VAR1 and VAR2. Since two, possibly distinct, values should be assigned to VAR1 and VAR2 and since these values belong to the same partition \( p \) the final graph should only have one sink. This sink corresponds in fact to partition \( p \).

Parts (A) and (B) of Figure 5.432 respectively show the initial and final graph associated with the Example slot. Since we both use the NSOURCE and NSINK graph properties, the source and sink vertices of the final graph are shown with a double circle.

![Initial and final graph of the IN_SAME_PARTITION constraint](image)

Figure 5.432: Initial and final graph of the IN_SAME_PARTITION constraint

Signature

Note that the sinks of the initial graph cannot become sources of the final graph since isolated vertices are eliminated from the final graph. Since the final graph contains two sources it also includes one arc between a source and a sink. Therefore the minimum number of sinks of the final graph is equal to one. So we can rewrite \text{NSINK} = 1 to \text{NSINK} \geq 1 and simplify \text{NSINK} to \text{NSINK}. 
Automaton

Figure 5.433 depicts the automaton associated with the INSAME_PARTITION constraint. Let \(\text{VALUES}_i\) be the \(p\) attribute of the \(i^{th}\) item of the PARTITIONS collection. To each triple \((\text{VAR1}, \text{VAR2}, \text{VALUES}_i)\) corresponds a 0-1 signature variable \(S_i\) as well as the following signature constraint:

\[
((\text{VAR1} \in \text{VALUES}_i) \land (\text{VAR2} \in \text{VALUES}_i)) \Leftrightarrow S_i.
\]

Figure 5.433: Automaton of the INSAME_PARTITION constraint

Figure 5.434: Hypergraph of the reformulation corresponding to the automaton of the INSAME_PARTITION constraint
5.185  **IN_SET**

**DESCRIPTION**

**Origin**
Used for defining constraints with set variables.

**Constraint**
\[ \text{IN\_SET}(\text{VAL}, \text{SET}) \]

**Synonyms**
DOM, MEMBER.

**Arguments**
- **VAL**: dvar
- **SET**: svar

**Purpose**
Constraint variable VAL to belong to set SET.

**Example**
\[ (3, \{1, 3\}) \]

**Remark**
When SET is fixed the IN_SET constraint is referenced under the name DOM in Gecode.

**Systems**
MEMBER in Choco, REL in Gecode, DOM in Gecode.

**Used in**
BIPARTITE, CLIQUE, CONNECTED, CUTSET, DAG, DISCREPANCY, DISJ, INVERSE\_SET, K\_CUT, LINK\_SET\_TO\_BOOLEANS, OPEN\_ALLDIFFERENT, OPEN\_AMONG, OPEN\_ATLEAST, OPEN\_ATMOST, OPEN\_GLOBAL\_CARDINALITY, OPEN\_GLOBAL\_CARDINALITY\_LOW\_UP, PATH\_FROM\_TO, PROPER\_FOREST, ROOTS, STRONGLY\_CONNECTED, SUM, SUM\_SET, SYMMETRIC, SYMMETRIC\_CARDINALITY, SYMMETRIC\_GCC, TOUR.

**See also**

\( \text{INCOMPARABLES}. \)

\( \text{VECTOR1} : \text{collection}(\text{var}-\text{dvar}) \)

\( \text{VECTOR2} : \text{collection}(\text{var}-\text{dvar}) \)

Enforce that when the components of \( \text{VECTOR1} \) and \( \text{VECTOR2} \) are ordered, and respectively denoted by \( \text{SVVECTOR1}[i].\text{var} \leq \text{SVVECTOR2}[i].\text{var} \) (for all \( i \in [1,|\text{SVVECTOR1}|] \)) nor have \( \text{SVVECTOR2}[i].\text{var} \leq \text{SVVECTOR1}[i].\text{var} \) (for all \( i \in [1,|\text{SVVECTOR1}|] \)).

\( (\langle 16,2 \rangle,\langle 4,11 \rangle) \)

The \text{INCOMPARABLE} constraint holds since \( 16 > 4 \) and \( 2 < 11 \).

\(|\text{VECTOR1}| > 1 \)

- Items of \( \text{VECTOR1} \) are \text{permutable}.
- Items of \( \text{VECTOR2} \) are \text{permutable}.
- Arguments are \text{permutable} \text{w.r.t.} permutation \( (\text{VECTOR1, VECTOR2}) \).

\( \text{ALL_INCOMPARABLE} \).

\text{implies: LEX_DIFFERENT.}

\text{system of constraints: ALL_INCOMPARABLE.}

\text{characteristic of a constraint: vector.}

\text{constraint arguments: constraint between two collections of variables.}

\text{constraint type: predefined constraint.}
Cond. implications

• \textsc{incomparable} \( (\text{VECTOR}_1, \text{VECTOR}_2) \) with \( |\text{VECTOR}_1| = 2 \) implies \textsc{disjoint} \( (\text{VARIABLES}_1 : \text{VECTOR}_1, \text{VARIABLES}_2 : \text{VECTOR}_2) \).

• \textsc{incomparable} \( (\text{VECTOR}_1, \text{VECTOR}_2) \) with \( |\text{VECTOR}_1| = 2 \) implies \textsc{int-value-precede-chain} \( (\text{VALUES} : \text{VECTOR}_1, \text{VARIABLES} : \text{VECTOR}_2) \).
5.187 INCREASING

Description

Origin: KOALOG

Constraint: INCREASING(VARIABLES)

Argument: VARIABLES : collection(var−dvar)

Restriction: required(VARIABLES,var)

Purpose: The variables of the collection VARIABLES are increasing.

Example: ((1, 1, 4, 8))

The INCREASING constraint holds since 1 ≤ 1 ≤ 4 ≤ 8.

Typical: |VARIABLES| > 2

Typical model: nval(VARIABLES.var) > 2

Symmetry: One and the same constant can be added to the var attribute of all items of VARIABLES.

Arg. properties: Contractible wrt. VARIABLES.

Counting:

Figure 5.435: Initial and final graph of the INCREASING constraint
Figure 5.436 depicts the automaton associated with the INCREASING constraint. To each pair of consecutive variables \((VAR_i, VAR_{i+1})\) of the collection \(VARIABLES\) corresponds a 0-1 signature variable \(S_i\). The following signature constraint links \(VAR_i, VAR_{i+1}\) and \(S_i\): 

\[ \text{VAR}_i \leq \text{VAR}_{i+1} \Leftrightarrow S_i. \]

Figure 5.436: Automaton of the INCREASING constraint

Figure 5.437: Hypergraph of the reformulation corresponding to the automaton of the INCREASING constraint
### 5.188 INCREASING_GLOBAL_CARDINALITY

**Origin**
Conjoin `GLOBAL_CARDINALITY_LOW_UP` and `INCREASING`.

**Constraint**

\[
\text{INCREASING_GLOBAL_CARDINALITY} (\text{VARIABLES, VALUES})
\]

**Synonyms**

\[
\text{INCREASINGGLOBAL_CARDINALITY_LOW_UP}, \quad \text{INCREASING_GCC}, \quad \text{INCREASING_GCC_LOW_UP}.
\]

**Arguments**

- `VARIABLES`: \(\text{collection} (\text{var} - \text{dvar})\)
- `VALUES`: \(\text{collection} (\text{val} - \text{int}, \text{omin} - \text{int}, \text{omax} - \text{int})\)

**Restrictions**

- `required`(`VARIABLES`, `var`)
- `INCREASING`(`VARIABLES`)
- `required`(`VALUES`, `[val, omin, omax]`)
- `distinct`(`VALUES`, `val`)
- `VALUES.omin \geq 0`
- `VALUES.omax \leq |\text{VARIABLES}|`
- `VALUES.omin \leq VALUES.omax`

**Purpose**
The variables of the collection `VARIABLES` are increasing. In addition, each value `VALUES[i].val` \((1 \leq i \leq |\text{VALUES}|)\) should be taken by at least `VALUES[i].omin` and at most `VALUES[i].omax` variables of the `VARIABLES` collection.

**Example**

\[
\begin{pmatrix}
(3, 3, 6, 8), \\
\text{val} - 3 \quad \text{omin} - 2 \quad \text{omax} - 3, \\
\text{val} - 5 \quad \text{omin} - 0 \quad \text{omax} - 1, \\
\text{val} - 6 \quad \text{omin} - 1 \quad \text{omax} - 2
\end{pmatrix}
\]

The `INCREASING_GLOBAL_CARDINALITY` constraint holds since:

- The values of the collection \((3, 3, 6, 8)\) are sorted in increasing order.
- Values 3, 5 and 6 are respectively used \(2 \leq 2 \leq 3\), \(0 \leq 0 \leq 1\) and \(1 \leq 1 \leq 2\) times within the collection \((3, 3, 6, 8)\) and since no constraint was specified for value 8.

**Typical**

- `|\text{VARIABLES}| > 1`
- `\text{range} (\text{VARIABLES.var}) > 1`
- `|\text{VALUES}| > 1`
- `\text{VALUES.omin} \leq |\text{VARIABLES}|`
- `\text{VALUES.omax} > 0`
- `\text{VALUES.omax} \leq |\text{VARIABLES}|`
- `|\text{VARIABLES}| > |\text{VALUES}|`
INCREASING_GLOBAL_CARDINALITY

Typical model

\[ nval(VARIABLES:var) > 2 \]

Symmetry

Items of VALUES are permutable.

Usage

This constraint can be used in order to break symmetry in the context of the following pattern. We have a matrix \( M \) of variables with the same constraint on each row and a \( \text{GLOBAL\_CARDINALITY\_LOW\_UP} \) constraint on each column. Beside lexicographically ordering the rows of \( M \) with a \( \text{LEX\_CHAIN\_LESSEQ} \) constraint, one can also state a \( \text{INCREASING\_GLOBAL\_CARDINALITY} \) on the first column of \( M \) in order to improve propagation on the corresponding variables.

Reformulation

The \( \text{INCREASING\_GLOBAL\_CARDINALITY} \) constraint can be expressed in term of a conjunction of a \( \text{GLOBAL\_CARDINALITY\_LOW\_UP} \) and an \( \text{INCREASING} \) constraints. Even if we achieve arc-consistency on these two constraints this hinders propagation as shown by the following small example.

We have two variables \( X \) and \( Y \) \((X \leq Y)\), which both take their values in the set \{2, 3\}. In addition, assume that the minimum number of occurrences of values 0, 1 and 2 are respectively equal to 0, 1 and 1. Similarly assume that, the maximum number of occurrences of values 0, 1 and 2 are respectively equal to 1, 1 and 2. The reformulation does not reduce the domain of variables \( X, Y \) in any way, while the automaton described in the Automaton slot fixes \( X \) to 2 and \( Y \) to 3.

See also

\textbf{implies:} \text{GLOBAL\_CARDINALITY\_LOW\_UP, INCREASING}.

\textbf{related:} \text{ORDERED\_GLOBAL\_CARDINALITY}.

Keywords

\textbf{application area:} assignment.

\textbf{characteristic of a constraint:} automaton, automaton without counters, reified automaton constraint.

\textbf{constraint network structure:} Berge-acyclic constraint network.

\textbf{constraint type:} value constraint, order constraint.

\textbf{filtering:} arc-consistency.

\textbf{symmetry:} symmetry, matrix symmetry.
For all items of \texttt{VALUES}:

\begin{itemize}
  \item \texttt{Arc input(s)} \hspace{1cm} \texttt{VARIABLES}
  \item \texttt{Arc generator} \hspace{1cm} \texttt{SELF} \mapsto \texttt{collection(variables)}
  \item \texttt{Arc arity} \hspace{1cm} 1
  \item \texttt{Arc constraint(s)} \hspace{1cm} \texttt{variables.var = VALUES.val}
  \item \texttt{Graph property(ies)} \hspace{1cm} \begin{itemize}
    \item \texttt{NVERTEX} \geq \texttt{VALUES.omin}
    \item \texttt{NVERTEX} \leq \texttt{VALUES.omax}
  \end{itemize}
\end{itemize}

\textbf{Graph model}

Since we want to express one unary constraint for each value we use the “For all items of \texttt{VALUES}” iterator. Part (A) of Figure 5.438 shows the initial graphs associated with each value 3, 5 and 6 of the \texttt{VALUES} collection of the \texttt{Example} slot. Part (B) of Figure 5.438 shows the two corresponding final graphs respectively associated with values 3 and 6 that are both assigned to the variables of the \texttt{VARIABLES} collection (since value 5 is not assigned to any variable of the \texttt{VARIABLES} collection the final graph associated with value 5 is empty). Since we use the \texttt{NVERTEX} graph property, the vertices of the final graphs are stressed in bold.

![Figure 5.438: Initial and final graph of the INCREASING\_GLOBAL\_CARDINALITY constraint](image-url)
A first systematic approach for creating an automaton that only recognises the solutions to the `INCREASING_GLOBAL_CARDINALITY` constraint could be to:

- First, create an automaton that recognises the solutions to the `INCREASING` constraint.
- Second, create an automaton that recognises the solutions to the `GLOBAL_CARDINALITY_LOW_UP` constraint.
- Third, make the product of the two previous automata and minimise the resulting automaton.

However, this approach is not going to scale well in practice since the automaton associated with the `GLOBAL_CARDINALITY_LOW_UP` constraint may have a too big size. Therefore, we propose an approach where we directly construct in a single step the automaton that only recognises the solutions to the `INCREASING_GLOBAL_CARDINALITY` constraint. Note that we do not have any formal proof that the resulting automaton is always minimum.

Without loss of generality, we assume that:

- All items of the `VALUES` collection are sorted in increasing value on the attribute `val`.
- All the potential values of the variables of the `VARIABLES` collection are included within the set of values of the collection `VALUES` (i.e., the `val` attribute).
- All values of the `VALUES` collection for which the attribute `omax` is set to 0 cannot be assigned to the variables of the `VARIABLES` collection.

Before defining the states of the automaton, we first need to introduce the following notion. A value `VALUES[v].val` is constrained by its maximum number of occurrences if and only if `VALUES[v].omax ≤ 1` or `VALUES[v].omax < |VARIABLES| - \sum_{u=1}^{|VALUES|} VALUES[u].omin`.

Let \( \mathcal{V} \) denote the set of constrained values (i.e., their indexes within the collection `VALUES`) by their respective maximum number of occurrences.

After determining the set \( \mathcal{V} \), the `omax` attribute of each potential value is normalised in the following way:

- For an unconstrained value `VALUES[v].val` we reset `VALUES[v].omax` to \( \max(1, VALUES[v].omin) \).
- For a constrained value `VALUES[v].val` we reset `VALUES[v].omax` to 1 if its current value is smaller than 1.

We are now in position to introduce the states of the automaton.

The \( 1 + \sum_{v=1}^{|VALUES|} VALUES[v].omax + \sum_{v=1}^{|VALUES|} VALUES[v].omin \) states of the automaton that only accept solutions to the `INCREASING_GLOBAL_CARDINALITY` constraint are defined in the following way:

- For the \( v \)-th item of the collection `VALUES` we have:
  - If \( v ∈ \mathcal{V} \), `VALUES[v].omax` states labelled by \( s_v o \) (\( 1 ≤ o ≤ VALUES[v].omax \)).

---

9 If this is not the case, we can include these values within the `VALUES` collection and set their minimum and maximum number of occurrences to 0 and \( |VARIABLES| - \sum_{v=1}^{|VALUES|} VALUES[v].omin \).
10 We initially remove such values from all variables of the `VARIABLES` collection.
11 When `VALUES[v].omax ≤ 1` we cannot reduce the number of states related to value `VALUES[v].val` and we therefore consider that we are in the constrained case.
The at least comes from the loop on state $s_{12}$. 

---

12The at least comes from the loop on state $s_{12}$. 

---

---
Figure 5.439: Automaton of the INCREASING_GLOBAL_CARDINALITY constraint of the Example slot: the path corresponding to the solution \( \langle 3, 3, 6, 8 \rangle \) is depicted by thick orange arcs.
5.189  **INCREASING_NVALUE**

**Origin**
Conjoin \( \text{NVALUE} \) and \( \text{INCREASING} \).

**Constraint**
\( \text{INCREASING_NVALUE}(\text{NVAL}, \text{VARIABLES}) \)

**Arguments**
- \( \text{NVAL} \): \text{dvar}
- \( \text{VARIABLES} \): \text{collection(\text{var--dvar})}

**Restrictions**
- \( \text{NVAL} \geq \min(1, |\text{VARIABLES}|) \)
- \( \text{NVAL} \leq |\text{VARIABLES}| \)
- \( \text{required}(\text{VARIABLES}, \text{var}) \)
- \( \text{INCREASING}(\text{VARIABLES}) \)

**Purpose**
The variables of the collection \( \text{VARIABLES} \) are increasing. In addition, \( \text{NVAL} \) is the number of distinct values taken by the variables of the collection \( \text{VARIABLES} \).

**Example**
\( (2, (6, 6, 8, 8, 8)) \)
\( (1, (6, 6, 6, 6, 6)) \)
\( (5, (0, 2, 3, 6, 7)) \)

The first \( \text{INCREASING_NVALUE} \) constraint (see Figure 5.440 for a graphical representation) holds since:

- The values of the collection \( (6, 6, 8, 8, 8) \) are sorted in increasing order.
- \( \text{NVAL} = 2 \) is set to the number of distinct values occurring within the collection \( (6, 6, 8, 8, 8) \).

![Figure 5.440](image-url)

Figure 5.440: Illustration of the first example of the **Example** slot: five variables \( V_1, V_2, V_3, V_4, V_5 \) respectively fixed to values 6, 6, 8, 8 and 8, and the corresponding number of distinct values \( \text{NVAL} = 2 \).

Arg. properties

Functional dependency: NVAL determined by VARIABLES.

Algorithm

A complete filtering algorithm in a linear time complexity over the sum of the domain sizes is described in [51].

Reformulation

The INCREASING_NVALUE constraint can be expressed in term of a conjunction of a NVALUE and an INCREASING constraints (i.e., a chain of non strict inequality constraints on adjacent variables of the collection VARIABLES). But as shown by the following example, \( V_1 \in [1, 2], V_2 \in [1, 2], V_1 \leq V_2, \text{NVALUE}(2, \langle V_1, V_2 \rangle) \), this hinders propagation (i.e., the unique solution \( V_1 = 1, V_2 = 2 \) is not directly obtained after stating all the previous constraints).

A better reformulation achieving arc-consistency uses the SEQ_BIN constraint [321] that we now introduce. Given a domain variable, \( X \) a sequence of domain variables, and \( C \) and \( B \) two binary constraints, SEQ_BIN(\( N, X, C, B \)) holds if (1) \( N \) is equal to the number of \( C \)-stretches in the sequence \( X \), and (2) \( B \) holds on any pair of consecutive variables in \( X \). A \( C \)-stretch is a generalisation of the notion of stretch introduced by G. Pesant [316], where the equality constraint is made explicit by replacing it by a binary constraint \( C \), i.e., a \( C \)-stretch is a maximal length subsequence of \( X \) for which the binary constraint \( C \) is satisfied on consecutive variables. INCREASING_NVALUE(NVAL, VARIABLES) can be reformulated as SEQ_BIN(NVAL, VARIABLES, =, \leq).

Graph model

Parts (A) and (B) of Figure 5.441 respectively show the initial and final graph associated with the first example of the Example slot. Since we use the NSCC graph property, we show the different strongly connected components of the final graph. Each strongly connected component corresponds to a value that is assigned to some variables of the VARIABLES collection. The 2 following values 6 and 8 are used by the variables of the VARIABLES collection.

![Figure 5.441: Initial and final graph of the INCREASING_NVALUE constraint](image-url)
A first systematic approach for creating an automaton that only recognises the solutions to the \textsc{increasing}_{NVALUE} constraint could be to:

- First, create an automaton that recognises the solutions to the \textsc{increasing} constraint.
- Second, create an automaton that recognises the solutions to the \textsc{NValue} constraint.
- Third, make the product of the two previous automata and minimise the resulting automaton.

However this approach is not going to scale well in practice since the automaton associated with the \textsc{NValue} constraint has a too big size. Therefore we propose an approach where we directly construct in a single step the automaton that only recognises the solutions to the \textsc{increasing}_{NVALUE} constraint. Note that we do not have any formal proof that the resulting automaton is always minimum.

Without loss of generality, assume that the collection of variables \textsc{variables} contains at least one variable (i.e., $|\textsc{variables}| \geq 1$). Let $l$, $m$, $n$, $\text{min}$ and $\text{max}$ respectively denote the minimum and maximum possible value of variable \textsc{NVal}, the number of variables of the collection \textsc{variables}, the smallest value that can be assigned to the variables of \textsc{variables}, and the largest value that can be assigned to the variables of \textsc{variables}. Let $s = \text{max} - \text{min} + 1$ denote the total number of potential values. Clearly, the maximum number of distinct values that can be assigned to the variables of the collection \textsc{variables} cannot exceed the quantity $d = \min(m, n, s)$. The $s^2 - (s-\text{max})(s-\text{max}+1)/2 + 1$ states of the automaton that only accepts solutions to the \textsc{increasing}_{NVALUE} constraint can be defined in the following way:

- We have an initial state labelled by $s_{00}$.
- We have $\frac{s(s+1)}{2} - \frac{(s-d)(s-d+1)}{2}$ states labelled by $s_{ij}$ ($1 \leq i \leq d$, $i \leq j \leq s$). The first index $i$ of a state $s_{ij}$ corresponds to the number of distinct values already encountered, while the second index $j$ denotes the the current value (i.e., more precisely the index of the current value, where the minimum value has index 1).

Terminal states depend on the possible values of variable \textsc{NVal} and correspond to those states $s_{ij}$ such that $i$ is a possible value for variable \textsc{NVal}. Note that we assume no further restriction on the domain of \textsc{NVal} (otherwise the set of accepting states needs to be reduced in order to reflect the current set of possible values of \textsc{NVal}). Three classes of transitions are respectively defined in the following way:

1. There is a transition, labelled by $\text{min} + j - 1$, from the initial state $s_{00}$ to the state $s_{1j}$ ($1 \leq j \leq s$).
2. There is a loop, labelled by $\text{min} + j - 1$ for every state $s_{ij}$ ($1 \leq i \leq d$, $i \leq j \leq s$).
3. \forall i \in [1,d-1], \forall j \in [i,s], \forall k \in [j+1,s]$ there is a transition labelled by $\text{min} + k - 1$ from $s_{ij}$ to $s_{i+1,k}$.

We respectively have $s$ transitions of class 1, $\frac{s(s+1)}{2} - \frac{(s-d)(s-d+1)}{2}$ transitions of class 2, and $\frac{s(s+1)}{6} - \frac{(s-d)(s-d+1)(s-d+2)}{6}$ transitions of class 3.

Note that all states $s_{ij}$ such that $i + s - j < l$ can be discarded since they do not allow to reach the minimum number of distinct values required $l$. 

**Automaton**
Part (A) of Figure 5.442 depicts the automaton associated with the `INCREASING_NVALUE` constraint of the first example of the `Example` slot. For this purpose, we assume that variable `NVAL` is fixed to value 2 and that variables of the collection `VARIABLES` take their values within interval $[6, 8]$. Part (B) of Figure 5.442 represents the simplified automaton where all states that do not allow to reach an accepting state were removed. The corresponding `INCREASING_GLOBAL_CARDINALITY` constraint holds since the corresponding sequence of visited states, $s_0 \ s_1 \ s_2 \ s_3$, ends up in an accepting state (i.e., accepting states are denoted graphically by a double circle).

Figure 5.442: Automaton – Part (A) – and simplified automaton – Part (B) – of the `INCREASING_NVALUE(2, (6, 6, 8, 8))` constraint of the first example of the `Example` slot: the path corresponding to the second argument $(6, 6, 8, 8)$ is depicted by thick orange arcs, where the self-loop on state $s_3$ is applied twice.

Figure 5.443 depicts a second deterministic automaton with one counter associated with the `INCREASING_NVALUE` constraint, where the argument `NVAL` is unified to the final value of the counter.

Figure 5.443: Automaton (with one counter) of the `INCREASING_NVALUE` constraint for a non-empty collection of variables
5.190 INCREASING_NVALUE_CHAIN

Origin
Derived from INCREASING_NVALUE.

Constraint
INCREASING_NVALUE_CHAIN(NVAL, VARIABLES)

Arguments
NVAL : dvar
VARIABLES : collection(b−dvar, var−dvar)

Restrictions
NVAL ≥ min(1, |VARIABLES|)
NVAL ≤ |VARIABLES|
required(VARIABLES, [b, var])
VARIABLES.b ≥ 0
VARIABLES.b ≤ 1

Purpose
For each consecutive pair of items VARIABLES[i], VARIABLES[i + 1] (1 ≤ i < |VARIABLES|) of the VARIABLES collection at least one of the following conditions hold:
1. VARIABLES[i + 1].b = 0,
2. VARIABLES[i].var ≤ VARIABLES[i + 1].var.

In addition, NVAL is equal to number of pairs of variables VARIABLES[i], VARIABLES[i + 1] (1 ≤ i < |VARIABLES|) plus one, which verify at least one of the following conditions:
1. VARIABLES[i + 1].b = 0,
2. VARIABLES[i].var < VARIABLES[i + 1].var.

Note that VARIABLES[1].b is not referenced at all in the previous definition (i.e., its value does not influence at all the values assigned to the other variables).

Example

\[
\begin{pmatrix}
  b - 0 & var - 2, \\
  b - 1 & var - 4, \\
  b - 1 & var - 4, \\
  b - 1 & var - 4, \\
  b - 0 & var - 4, \\
  b - 1 & var - 8, \\
  b - 0 & var - 1, \\
  b - 0 & var - 7, \\
  b - 1 & var - 7
\end{pmatrix}
\]

The INCREASING_NVALUE_CHAIN constraint holds since:
1. The condition VARIABLES[i + 1].b = 0 ∨ VARIABLES[i].var ≤ VARIABLES[i + 1].var holds for every pair of adjacent items of the VARIABLES collection:
• For the pair \((\text{VARIABLES}[1].\text{var}, \text{VARIABLES}[2].\text{var})\) we have \(\text{VARIABLES}[1].\text{var} \leq \text{VARIABLES}[2].\text{var} \ (2 \leq 4)\).

• For the pair \((\text{VARIABLES}[2].\text{var}, \text{VARIABLES}[3].\text{var})\) we have \(\text{VARIABLES}[2].\text{var} \leq \text{VARIABLES}[3].\text{var} \ (4 \leq 4)\).

• For the pair \((\text{VARIABLES}[3].\text{var}, \text{VARIABLES}[4].\text{var})\) we have \(\text{VARIABLES}[3].\text{var} \leq \text{VARIABLES}[4].\text{var} \ (4 \leq 4)\).

• For the pair \((\text{VARIABLES}[4].\text{var}, \text{VARIABLES}[5].\text{var})\) we have \(\text{VARIABLES}[4].\text{var} = 0\).

• For the pair \((\text{VARIABLES}[5].\text{var}, \text{VARIABLES}[6].\text{var})\) we have \(\text{VARIABLES}[5].\text{var} \leq \text{VARIABLES}[6].\text{var} \ (4 \leq 8)\).

• For the pair \((\text{VARIABLES}[6].\text{var}, \text{VARIABLES}[7].\text{var})\) we have \(\text{VARIABLES}[6].\text{var} = 0\).

• For the pair \((\text{VARIABLES}[7].\text{var}, \text{VARIABLES}[8].\text{var})\) we have \(\text{VARIABLES}[7].\text{var} = 0\).

• For the pair \((\text{VARIABLES}[8].\text{var}, \text{VARIABLES}[9].\text{var})\) we have \(\text{VARIABLES}[8].\text{var} \leq \text{VARIABLES}[9].\text{var} \ (7 \leq 7)\).

2. \text{NVAL} is equal to number of pairs of variables \(\text{VARIABLES}[i].\text{var}, \text{VARIABLES}[i + 1].\text{var} \ (1 \leq i < |\text{VARIABLES}|)\) plus one which verify at least \(\text{VARIABLES}[i + 1].\text{b} = 0 \lor \text{VARIABLES}[i].\text{var} < \text{VARIABLES}[i + 1].\text{var} \). Beside the plus one, the following five pairs contribute for 1 in \text{NVAL}:

• For the pair \((\text{VARIABLES}[1].\text{var}, \text{VARIABLES}[2].\text{var})\) we have \(\text{VARIABLES}[1].\text{var} \leq \text{VARIABLES}[2].\text{var} \ (2 < 4)\).

• For the pair \((\text{VARIABLES}[4].\text{var}, \text{VARIABLES}[5].\text{var})\) we have \(\text{VARIABLES}[5].\text{var} = 0\).

• For the pair \((\text{VARIABLES}[5].\text{var}, \text{VARIABLES}[6].\text{var})\) we have \(\text{VARIABLES}[5].\text{var} \leq \text{VARIABLES}[6].\text{var} \ (4 < 8)\).

• For the pair \((\text{VARIABLES}[6].\text{var}, \text{VARIABLES}[7].\text{var})\) we have \(\text{VARIABLES}[6].\text{var} = 0\).

• For the pair \((\text{VARIABLES}[7].\text{var}, \text{VARIABLES}[8].\text{var})\) we have \(\text{VARIABLES}[8].\text{var} = 0\).

\begin{align*}
\text{Typical} & \quad |\text{VARIABLES}| > 1 \\
& \quad \text{range}(|\text{VARIABLES}.\text{b}|) > 1 \\
& \quad \text{range}(|\text{VARIABLES}.\text{var}|) > 1
\end{align*}

Graph model

Parts (A) and (B) of Figure 5.444 respectively show the initial and final graph associated with the second graph constraint of the Example slot. Since we use the NARC graph property the arcs of the final graph are stressed in bold.

Figure 5.444: Initial and final graph of the INCREASING_NVALUE_CHAIN constraint
Without loss of generality, assume that the collection VARIABLES contains at least one variable (i.e., $|\text{VARIABLES}| \geq 1$). Let $l, m, n, \text{min}$ and $\text{max}$ respectively denote the minimum and maximum possible value of variable NVAL, the number of items of the collection VARIABLES, the smallest value that can be assigned to VARIABLES[i].var ($1 \leq i \leq n$), and the largest value that can be assigned to VARIABLES[i].var ($1 \leq i \leq n$). Let $s = \text{max} - \text{min} + 1$ denote the total number of potential values. Clearly, the maximum value of NVAL cannot exceed the quantity $d = \text{min}(m, n)$. The states of the automaton that only accepts solutions to the INCREASING_NVALUE_CHAIN constraint can be defined in the following way:

- We have an initial state labelled by $s_{00}$.
- We have $d \cdot s$ states labelled by $s_{ij}$ ($1 \leq i \leq d$, $1 \leq j \leq s$).

Terminal states depend on the possible values of variable NVAL and correspond to those states $s_{ij}$ such that $i$ is a possible value for variable NVAL. Note that we assume no further restriction on the domain of NVAL (otherwise the set of accepting states needs to be reduced in order to reflect the current set of possible values of NVAL).

Transitions of the automaton are labelled by a pair of values $(\alpha, \beta)$ and correspond to a condition of the form VARIABLES[i].b = $\alpha \land$ VARIABLES[i].var = $\beta$ ($1 \leq i \leq n$). Characters * and + respectively represent all values in \{0, 1\} and all values in \{min, min + 1, \ldots, max\}. Four classes of transitions are respectively defined in the following way:

1. There is a transition, labelled by the pair $(\ast, \min + j - 1)$, from the initial state $s_{00}$ to the state $s_{1j}$ ($1 \leq j \leq s$). We use the * character since VARIABLES[1].b is not used at all in the definition of the INCREASING_NVALUE_CHAIN constraint.
2. There is a loop, labelled by the pair $(1, \min + j - 1)$ for every state $s_{ij}$ ($1 \leq i \leq d, 1 \leq j \leq s$).
3. $\forall i \in [1, d - 1], \forall j \in [1, s], \forall k \in [j + 1, s]$ there is a transition labelled by the pair $(1, \min + k - 1)$ from $s_{ij}$ to $s_{i+1k}$.
4. $\forall i \in [1, d - 1], \forall j \in [1, s]$ there is a transition labelled by the pair $(0, +)$ from $s_{ij}$ to $s_{i+11}$.
INCREASING_NVALUE_CHAIN

Figure 5.445: Automaton of the INCREASING_NVALUE_CHAIN constraint under the hypothesis that all variables are assigned a value in \{6, 7, 8\} and that NVAL is equal to 2. The character * on a transition corresponds to a 0 or to a 1 and the + corresponds to a 6, 7 or 8.
5.191 INCREASING\_PEAK

**Description**

Origin: Derived from PEAK and INCREASING.

Constraint: \( \text{INCREASING\_PEAK}(\text{VARIABLES}) \)

Argument: \( \text{VARIABLES} : \text{collection}(\text{var\text{-}dvar}) \)

Restrictions:

\[ |\text{VARIABLES}| > 0 \]
\[ \text{required}(\text{VARIABLES}, \text{var}) \]

A variable \( V_k \) (for \( 1 < k < m \)) of the sequence of variables \( \text{VARIABLES} = V_1, \ldots, V_m \) is a peak if and only if there exists an \( i \) (for \( 1 < i \leq k \)) such that \( V_{i-1} < V_i \) and \( V_i = V_{i+1} = \cdots = V_k \) and \( V_k > V_{k+1} \).

**Purpose**

When considering all the peaks of the sequence \( \text{VARIABLES} \) from left to right, enforce all peaks to be increasing, i.e., the altitude of each peak is greater than or equal to the altitude of its preceding peak when it exists.

**Example**

\( (1, 5, 5, 3, 5, 2, 2, 7, 4) \)

The \( \text{INCREASING\_PEAK} \) constraint holds since the sequence \( 1 \ 5 \ 5 \ 3 \ 5 \ 2 \ 2 \ 7 \ 4 \) contains three peaks, in bold, that are increasing.

Figure 5.446: Illustration of the Example slot: a sequence of ten variables \( V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10} \) respectively fixed to values \( 1, 5, 5, 3, 5, 2, 2, 7, 4 \) and its corresponding three peaks, in red, respectively located at altitudes 5, 5 and 7.
Typical

\[ |\text{VARIABLES}| \geq 7 \]
\[ \text{range}(\text{VARIABLES}.\text{var}) > 1 \]
\[ \text{PEAK}(\text{VARIABLES}.\text{var}) \geq 3 \]

Typical model

\[ n\text{val}(\text{VARIABLES}.\text{var}) > 2 \]

Symmetry

One and the same constant can be added to the \text{var} attribute of all items of \text{VARIABLES}.

Arg. properties

- Prefix-contractible wrt. \text{VARIABLES}.
- Suffix-contractible wrt. \text{VARIABLES}.

Number of solutions for \text{INCREASING\_PEAK}: domains 0..\(n\)

Solution density for \text{INCREASING\_PEAK}
See also

implied by: ALL_EQUAL_PEAK.
related: DECREASING_PEAK, PEAK.

Keywords

characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.
combinatorial object: sequence.
constraint network structure: sliding cyclic(1) constraint network(2).

Cond. implications

INCREASING_PEAK(VARIABLES)
with PEAK(VARIABLES.var) > 0
implies NOT_ALL_EQUAL(VARIABLES).
Automaton

Figure 5.447 depicts the automaton associated with the INCREASING_PEAK constraint. To each pair of consecutive variables (VAR_i, VAR_{i+1}) of the collection VARIABLES corresponds a signature variable S_i. The following signature constraint links VAR_i, VAR_{i+1} and S_i:

\[(\text{VAR}_i < \text{VAR}_{i+1} \iff S_i = 0) \land (\text{VAR}_i = \text{VAR}_{i+1} \iff S_i = 1) \land (\text{VAR}_i > \text{VAR}_{i+1} \iff S_i = 2).\]

**STATE SEMANTICS**

s : initial stationary or decreasing mode \((\{= | >\}^*)\)

u : increasing (before first potential peak) mode \((\{< | =\}^*)\)

v : decreasing (after a peak) mode \((\{> | =\}^*)\)

w : increasing (after a peak) mode \((\{< | =\}^*)\)

\{Altitude ← 0\} → VAR_i < VAR_{i+1}

VAR_i ≥ VAR_{i+1} → VAR_i ≤ VAR_{i+1}

VAR_i > VAR_{i+1}, \{Altitude ≤ VAR_i, Altitude ← VAR_i\} → VAR_i > VAR_{i+1}, \{Altitude ← VAR_i\}

VAR_i ≤ VAR_{i+1} → VAR_i ≥ VAR_{i+1}

VAR_i < VAR_{i+1}

Figure 5.447: Automaton for the INCREASING_PEAK constraint (note the conditional transition from state w to state v testing that the counter Altitude is less than or equal to VAR_i for enforcing that all peaks from left to right are in increasing altitude)

Figure 5.448: Hypergraph of the reformulation corresponding to the automaton of the INCREASING_PEAK constraint where \(A_i\) stands for the value of the counter Altitude (since all states of the automaton are accepting there is no restriction on the last variable \(Q_{n-1}\))

</table>
1. A normalisation phase adjusts the minimum and maximum value of variables \( x_0, x_1, \ldots, x_{n-1} \) with respect to the chain of inequalities \( x_0 \leq x_1 \leq \cdots \leq x_{n-1} \). A forward phase adjusts the minimum value of \( x_1, x_2, \ldots, x_{n-1} \) (i.e., \( x_{i+1} \geq x_i \)), while a backward phase adjusts the maximum value of \( x_{n-2}, x_{n-1}, \ldots, x_0 \) (i.e., \( x_{i-1} \leq x_i \)).

2. A phase restricts the minimum and maximum value of the sum variable \( s \) with respect to the chain of inequalities \( x_0 \leq x_1 \leq \cdots \leq x_{n-1} \) (i.e., \( \bar{x} \geq \sum_{0 \leq i < n} x_i \) and \( s \leq \sum_{0 \leq i < n} x_i \)).

3. A final phase reduces the minimum and maximum value of variables \( x_0, x_1, \ldots, x_{n-1} \) both from the bounds of \( s \) and from the chain of inequalities. Without loss of generality we now focus on the pruning of the maximum value of variables \( x_0, x_1, \ldots, x_{n-1} \). For this purpose we first need to introduce the notion of last intersecting index of a variable \( x_i \), denoted by \( \text{last}_i \). This corresponds to the greatest index in \([i+1, n-1]\) such that \( \tau_i > x_{\text{last}_i} \), or \( i \) if no such integer exists. Then the increase of the minimum value of \( s \) when \( x_i \) is equal to \( \tau_i \) is equal to \( \sum_{k \in [i, \text{last}_i]} (\tau_i - x_k) \). When this increase exceeds the available margin, i.e., \( s - \sum_{0 \leq i < n} x_i \), we update the maximum value of \( x_i \).

We illustrate a part of the final phase on the following example INCREASING\_SUM\((x_0, x_1, x_2, x_3, x_4, x_5, s)\), where \( x_0 \in [2, 6], x_1 \in [4, 7], x_2 \in [4, 7], x_3 \in [5, 7], x_4 \in [6, 9], x_5 \in [7, 9] \) and \( s \in [28, 29] \). Observe that the domains are consistent with the first two phases of the algorithm, since,

1. the minimum (and maximum) values of variables \( x_0, x_1, x_2, x_3, x_4, x_5 \) are increasing,
2. the sum of the minimum of the variables \( x_0, x_1, x_2, x_3, x_4, x_5 \), i.e., 28 is less than or equal to the maximum value of \( s \),
3. the sum of the maximum of the variables \( x_0, x_1, x_2, x_3, x_4, x_5 \), i.e., 45 is greater than or equal to the minimum value of \( s \).

Now, assume we want to know the increase of the minimum value of \( s \) when \( x_0 \) is set to its maximum value 6. First we compute the last intersecting index of variable \( x_0 \). Since \( x_4 \) is the last variable for which the minimum value is less than or equal to maximum value of \( x_0 \) we have \( \text{last}_0 = 4 \). The increase is equal to \( \sum_{k \in [0, 4]} (\tau_k - x_k) = (6 - 2) + (6 - 4) + (6 - 4) + (6 - 5) + (6 - 6) = 9 \). Since it exceeds the margin 29 - (2 + 4 + 5 + 6 + 7) = 1 we have to reduce the maximum value of \( x_0 \). How to do this incrementally is described in [324].

Solution count for INCREASING_SUM: domains 0...n
Solution density for INCREASING_SUM

See also common keyword: SUM_CTR (sum).

implies: INCREASING.
Keywords

- **characteristic of a constraint**: sum.
- **constraint type**: predefined constraint, order constraint, arithmetic constraint.
- **filtering**: bound-consistency.
- **modelling**: functional dependency.
- **symmetry**: symmetry.

Cond. implications

- \( \text{INCREASING\_SUM}(\text{VARIABLES}, S) \)
  with \( \text{minval}(\text{VARIABLES}.\text{var}) > 0 \)
  implies \( \text{ATMOST\_NVALUE}(S, \text{VARIABLES}) \).  

- \( \text{INCREASING\_SUM}(\text{VARIABLES}, S) \)
  with \( \text{minval}(\text{VARIABLES}.\text{var}) > 0 \)
  implies \( \text{SUM\_OF\_INCREMENTS}(\text{VARIABLES}, \text{LIMIT}) \).
5.193 INCREASING_VALLEY

**Origin**
Derived from VALLEY and INCREASING.

**Constraint**
INCREASING_VALLEY(VARIABLES)

**Argument**
VARIABLES : collection(var−dvar)

**Restrictions**
|VARIABLES| > 0
required(VARIABLES, var)

A variable \( V_k \) \((1 < k < m)\) of the sequence of variables \( \text{VARIABLES} = V_1, \ldots, V_m \) is a valley if and only if there exists an \( i \) \((1 < i \leq k)\) such that \( V_{i-1} > V_i \) and \( V_i = V_{i+1} = \cdots = V_k \) and \( V_k < V_{k+1} \).

When considering all the valleys of the sequence \( \text{VARIABLES} \) from left to right enforce all valleys to be increasing, i.e. the altitude of each valley is greater than or equal to the altitude of its preceding valley when it exists.

**Purpose**

When considering all the valleys of the sequence \( \text{VARIABLES} \) from left to right enforce all valleys to be increasing, i.e. the altitude of each valley is greater than or equal to the altitude of its preceding valley when it exists.

**Example**
\((3,5,1,4,3,5,3,7,2)\)

The INCREASING_VALLEY constraint holds since the sequence 3 5 1 4 3 5 3 3 7 2 contains three valleys, in bold, that are increasing.

Figure 5.449: Illustration of the Example slot: a sequence of ten variables \( V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8, V_9, V_{10} \) respectively fixed to values 3, 5, 1, 4, 3, 5, 3, 7, 2 and its corresponding three valleys, in red, respectively located at altitudes 1, 3 and 3.
**Typical**

\[
|\text{VARIABLES}| \geq 7 \\
\text{range}(\text{VARIABLES}.\var) > 1 \\
\text{VALLEY}(\text{VARIABLES}.\var) \geq 3
\]

**Typical model**

\[nval(\text{VARIABLES}.\var) > 2\]

**Symmetry**

One and the same constant can be added to the \texttt{var} attribute of all items of \texttt{VARIABLES}.

**Arg. properties**

- Prefix-contractible wrt. \texttt{VARIABLES}.
- Suffix-contractible wrt. \texttt{VARIABLES}.

**Counting**

Number of solutions for \texttt{INCREASING\_VALLEY}: domains $0..n$

**Solution density for \texttt{INCREASING\_VALLEY}**
Solution density for INCREASING VALLEY

See also
- implied by: ALL_EQUAL VALLEY.
- related: DECREASING VALLEY, VALLEY.

Keywords
- characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.
- combinatorial object: sequence.
- constraint network structure: sliding cyclic(1) constraint network(2).

Cond. implications
- INCREASING VALLEY(VARIABLES)
  with VALLEY(VARIABLES.var) > 0
  implies NOT ALL_EQUAL(VARIABLES).
Automaton

Figure 5.450 depicts the automaton associated with the INCREASING_VALLEY constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection \(\text{VARIABLES}\) corresponds a signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i, \text{VAR}_{i+1}\) and \(S_i\): \((\text{VAR}_i < \text{VAR}_{i+1} \iff S_i = 0) \land (\text{VAR}_i = \text{VAR}_{i+1} \iff S_i = 1) \land (\text{VAR}_i > \text{VAR}_{i+1} \iff S_i = 2)\).

STATE SEMANTICS

- \(s\) : initial stationary or increasing mode \((\{ = | < \}^*)\)
- \(u\) : decreasing (before first potential valley) mode \((> \{ > | = \}^*)\)
- \(v\) : increasing (after a valley) mode \((< \{ < | = \}^*)\)
- \(w\) : decreasing (after a valley) mode \((> \{ > | = \}^*)\)

\[
\begin{align*}
\{ \text{Altitude} \leftarrow 0 \} & \quad \text{VAR}_i > \text{VAR}_{i+1} \\
\text{VAR}_i \leq \text{VAR}_{i+1} & \quad \text{VAR}_i \geq \text{VAR}_{i+1} \\
\text{VAR}_i < \text{VAR}_{i+1}, \{ \text{Altitude} \leq \text{VAR}_i \} & \quad \{ \text{Altitude} \leftarrow \text{VAR}_i \} \\
\text{VAR}_i \geq \text{VAR}_{i+1} & \quad \text{VAR}_i \leq \text{VAR}_{i+1} \\
\text{VAR}_i > \text{VAR}_{i+1} &
\end{align*}
\]

Figure 5.450: Automaton for the INCREASING_VALLEY constraint (note the conditional transition from state \(w\) to state \(v\) testing that the counter \(\text{Altitude}\) is less than or equal to \(\text{VAR}_i\) for enforcing that all valleys from left to right are in increasing altitude)

Figure 5.451: Hypergraph of the reformulation corresponding to the automaton of the INCREASING_VALLEY constraint where \(A_i\) stands for the value of the counter \(\text{Altitude}\) (since all states of the automaton are accepting there is no restriction on the last variable \(Q_{n-1}\)).
5.194 INDEXED_SUM

Origin
N. Beldiceanu

Constraint
INDEXED_SUM(ITEMS, TABLE)

Arguments
ITEMS : collection(index—dvar, weight—dvar)
TABLE : collection(index—int, summation—dvar)

Restrictions
|ITEMS| > 0
|TABLE| > 0
required(ITEMS,[index, weight])
ITEMS.index ≥ 1
ITEMS.index ≤ |TABLE|
required(TABLE, [index, summation])
TABLE.index ≥ 1
TABLE.index ≤ |TABLE|
increasing_seq(TABLE, index)

Purpose
Given several items of the collection ITEMS (each of them having a specific fixed index as well as a weight that may be negative or positive), and a table TABLE (each entry of TABLE corresponding to a summation variable), assign each item to an entry of TABLE so that the sum of the weights of the items assigned to that entry is equal to the corresponding summation variable.

Example

\[
\begin{pmatrix}
  \text{index} & \text{weight} \\
  3 & -4 \\
  1 & -6 \\
  3 & -1 \\
  1 & -6 \\
  2 & -0 \\
  3 & -3
\end{pmatrix}
\]

The INDEXED_SUM constraint holds since the summation variables associated with each entry of TABLE are equal to the sum of the weights of the items assigned to the corresponding entry:

- TABLE[1].summation = ITEMS[2].weight = 6 (since TABLE[1].index = ITEMS[2].index = 1),
- TABLE[2].summation = 0 (since TABLE[2].index = 2 does not occur as a value of the index attribute of an item of ITEMS),
INDEXED_SUM

Typical

- $|\text{ITEMS}| > 1$
- $\text{range}(|\text{ITEMS}.\text{index}|) > 1$
- $|\text{TABLE}| > 1$
- $\text{range}(|\text{TABLE}.\text{summation}|) > 1$

Symmetries

- Items of $\text{ITEMS}$ are permutable.
- Items of $\text{TABLE}$ are permutable.

Reformulation

The INDEXED_SUM($\text{ITEMS}, \text{TABLE}$) constraint can be expressed in term of a set of reified constraints and of $|\text{TABLE}|$ arithmetic constraints (i.e., SCALAR_PRODUCT constraints).

1. For each item $\text{ITEMS}[i]$ ($i \in [1,|\text{ITEMS}|]$) and for each table entry $j$ ($j \in [1,|\text{TABLE}|]$) of $\text{TABLE}$ we create a 0-1 variable $B_{ij}$ that will be set to 1 if and only if $\text{ITEMS}[i].\text{index}$ is fixed to $j$ (i.e., $B_{ij} \iff \text{ITEMS}[i].\text{index} = j$).

2. For each entry $j$ of the table $\text{TABLE}$, we impose the sum $\text{ITEMS}[1].\text{weight} \cdot B_{1j} + \text{ITEMS}[2].\text{weight} \cdot B_{2j} + \cdots + \text{ITEMS}[|\text{ITEMS}|].\text{weight} \cdot B_{|\text{ITEMS}|j}$ to be equal to $\text{TABLE}[j].\text{summation}$.

See also

- implied by: ELEMENTS_ALLDIFFERENT.

Specialisation: BIN_PACKING (negative contribution not allowed, effective use variable for each bin replaced by an overall fixed capacity), BIN_PACKING_CAPA (negative contribution not allowed, effective use variable for each bin replaced by a fixed capacity for each bin).

Used in graph description: SUM_CTR.

Keywords

- application area: assignment.
- modelling: variable indexing, variable subscript.
For all items of TABLE:

<table>
<thead>
<tr>
<th>Arc input(s)</th>
<th>ITEMS TABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arc generator</td>
<td>PRODUCT.collection(items, table)</td>
</tr>
<tr>
<td>Arc arity</td>
<td>2</td>
</tr>
<tr>
<td>Arc constraint(s)</td>
<td>items.index = table.index</td>
</tr>
</tbody>
</table>
| Sets | SUCC \[\begin{array}{l}
\text{source}, \\
\text{variables} - \text{col (VARIABLES.collection(var, dvar),)} \\
\text{item(var - ITEMS.weight)}
\end{array}\] |
| Constraint(s) on sets | SUM.CTR(variables, =, TABLE.summation) |

**Graph model**

We enforce the SUM.CTR constraint on the weight of the items that are assigned to the same entry. Within the context of the Example slot, part (A) of Figure 5.452 shows the initial graphs associated with entries 1, 2 and 3 (i.e., one initial graph for each item of the TABLE collection). Part (B) of Figure 5.452 shows the corresponding final graphs associated with entries 1 and 3. Each source vertex of the final graph can be interpreted as an item assigned to a specific entry of TABLE.

![Initial and final graph of the INDEXED_SUM constraint](image)
5.195 INFLEXION

**Origin**
N. Beldiceanu

**Constraint**
INFLEXION\((N, VARIABLES)\)

**Arguments**
- \(N\) : dvar
- \(VARIABLES\) : collection(var–dvar)

**Restrictions**
\[N \geq 0\]
\[N \leq \max(0, |VARIABLES| - 2)\]
\[\text{required}(VARIABLES, \text{var})\]

\(N\) is equal to the number of times that the following conjunctions of constraints hold:
- \(X_i \text{CTR} X_{i+1} \land X_i \neq X_{i+1}\),
- \(X_{i+1} = X_{i+2} \land \cdots \land X_{j-2} = X_{j-1}\),
- \(X_{j-1} \neq X_j \land \text{CTR} X_j\).

where \(X_k\) is the \(k^{th}\) item of the \(VARIABLES\) collection and \(1 \leq i, i + 2 \leq j, j \leq n\) and \(\text{CTR}\) is \(<\) or \(>\).

**Example**
\[
\begin{align*}
(3, (1, 1, 4, 8, 8, 2, 7, 1))
\quad & 8 \quad 8 \\
(0, (1, 1, 4, 4, 6, 6, 7, 9))
\quad & 1 \quad 1 \\
(7, (1, 0, 2, 0, 7, 2, 7, 1, 2))
\quad & 7 \quad 7
\end{align*}
\]

The first INFLEXION constraint holds since the sequence 1 1 4 8 8 2 7 1 contains three inflexions peaks that respectively correspond to values 8, 2 and 7.

**All solutions**
Figure 5.454 gives all solutions to the following non ground instance of the INFLEXION constraint:
\[N \in \{0, 2\}, V_1 = 2, V_2 \in \{2, 3\}, V_3 \in \{1, 2\}, V_4 \in \{1, 2\}, V_5 = 3,\]
\[\text{INFLEXION}(N, (V_1, V_2, V_3, V_4, V_5))\].

**Typical**
- \(N > 0\)
- \(|VARIABLES| > 2\)
- \(\text{range}(VARIABLES\text{.var}) > 1\)

**Typical model**
\(\text{nval}(VARIABLES\text{.var}) > 2\)

**Symmetries**
- Items of \(VARIABLES\) can be reversed.
- One and the same constant can be added to the \(\text{var}\) attribute of all items of \(VARIABLES\).

**Arg. properties**
- Functional dependency: \(N\) determined by \(VARIABLES\).
Figure 5.453: Illustration of the first example of the Example slot: a sequence of eight variables \( V_1, V_2, V_3, V_4, V_5, V_6, V_7, V_8 \) respectively fixed to values 1, 1, 4, 8, 2, 7, 1 and its three inflexions in red, two peaks and one valley \( (N = 3) \)

Figure 5.454: All solutions corresponding to the non ground example of the INFLEXION constraint of the All solutions slot where each inflexion (i.e. peak or valley) is coloured in orange or cyan

**Usage**

Useful for constraining the number of inflexions of a sequence of domain variables.

**Remark**

Since the arity of the arc constraint is not fixed, the INFLEXION constraint cannot be currently described with the graph-based representation. However, this would not hold anymore if we were introducing a slot that specifies how to merge adjacent vertices of the final graph.

**Counting**

Solution count for INFLEXION: domains $0..n$

Solution density for INFLEXION

![Graph showing solution density for INFLEXION](image_url)
See also **common keyword**: GLOBAL_CONTIGUITY, MIN_DIST_BETWEEN_INFLEXION, PEAK, VALLEY (sequence).

**Keywords**

characteristic of a constraint: automaton, automaton with counters, automaton with same input symbol.

combinatorial object: sequence.

constraint arguments: reverse of a constraint, pure functional dependency.

constraint network structure: sliding cyclic(1) constraint network(2).

filtering: glue matrix.

modelling: functional dependency.

**Cond. implications**

- \( \text{INFLEXION}(N, \text{VARIABLES}) \)
  - with \( N > 0 \)
  - implies \( \text{ATLEAST}_N\text{VALUE}(N\text{VAL}, \text{VARIABLES}) \)
    - when \( N\text{VAL} = 2 \).

- \( \text{INFLEXION}(N, \text{VARIABLES}) \)
  - with \( \text{VALLEY}(\text{VARIABLES}.\text{var}) = 0 \)
  - implies \( \text{PEAK}(N, \text{VARIABLES}) \).

- \( \text{INFLEXION}(N, \text{VARIABLES}) \)
  - with \( \text{PEAK}(\text{VARIABLES}.\text{var}) = 0 \)
  - implies \( \text{VALLEY}(N, \text{VARIABLES}) \).
Automaton

Figure 5.455 depicts the automaton associated with the INFLEXION constraint. To each pair of consecutive variables \((\text{VAR}_i, \text{VAR}_{i+1})\) of the collection \(\text{VARIABLES}\) corresponds a signature variable \(S_i\). The following signature constraint links \(\text{VAR}_i, \text{VAR}_{i+1}\) and \(S_i\): \((\text{VAR}_i < \text{VAR}_{i+1} \Leftrightarrow S_i = 0) \land (\text{VAR}_i = \text{VAR}_{i+1} \Leftrightarrow S_i = 1) \land (\text{VAR}_i > \text{VAR}_{i+1} \Leftrightarrow S_i = 2)\).

STATE SEMANTICS

\[
\begin{align*}
\text{s} & : \text{stationary mode} & (=^*) & \text{VAR}_i = \text{VAR}_{i+1} \\
\text{i} & : \text{increasing mode} & (< | = | >^*) & \text{VAR}_i < \text{VAR}_{i+1} \\
\text{j} & : \text{decreasing mode} & (> | = | <^*) & \text{VAR}_i > \text{VAR}_{i+1}
\end{align*}
\]

\[
\begin{align*}
\text{VAR}_i < \text{VAR}_{i+1} & \Leftrightarrow \{C \leftarrow 0\} \\
\text{VAR}_i > \text{VAR}_{i+1} & \Leftrightarrow \{N = C\} \\
\text{VAR}_i \leq \text{VAR}_{i+1} & \Leftrightarrow \{\text{VAR}_i \geq \text{VAR}_{i+1}, \{C \leftarrow C + 1\}\} \\
\text{VAR}_i \geq \text{VAR}_{i+1} & \Leftrightarrow \{\text{VAR}_i < \text{VAR}_{i+1}, \{C \leftarrow C + 1\}\}
\end{align*}
\]

Figure 5.455: Automaton of the INFLEXION constraint (state \(s\) means that we are in stationary mode, state \(i\) means that we are in increasing mode, state \(j\) means that we are in decreasing mode, a new inflexion is detected each time we switch from increasing to decreasing mode – or conversely from decreasing to increasing mode – and the counter \(C\) is incremented accordingly).

Figure 5.456: Hypergraph of the reformulation corresponding to the automaton of the INFLEXION constraint
Glue matrix where $\overrightarrow{C}$ and $\overleftarrow{C}$ resp. represent the counter value $C$ at the end of a prefix and at the end of the corresponding reverse suffix that partitions the sequence $\text{VARIABLES}$. 

$\begin{array}{|c|c|c|}
\hline
s (\Rightarrow^*) & i (\Rightarrow \{< | = \}^*) & j (\Rightarrow \{> | = \}^*) \\
\hline
0 & \overrightarrow{C} & \overrightarrow{C} \\
\hline
\overrightarrow{C} & \overrightarrow{C} + 1 & \overrightarrow{C} + 1 \\
\hline
\end{array}$
